To those who believe in swabbings and a little stimulating whiskey or strychnine in the treatment of this disease, rather than depending upon the serum treatment, the observations of Dr. John H. McCollom will prove instructive. Dr. McCollom has had remarkable opportunities to study diphtheria, and is an authority on this subject. No case, he says, in an acute stage should be considered hopeless. "When one sees a patient with membrane covering the tonsils and uvula, profuse sanious discharge from the nose, spots of ecchymosis on the body and extremities, cold, clammy hands and feet, a feeble pulse, and the nauseous odor of diphtheria, and finds that after the administration of 10,000 units of antitoxin in two doses the condition of the patient improves slightly; that after 10,000 units more have been given there is a marked abatement in the severity of the symptoms; that when an additional 10,000 units have been given the patient is apparently out of danger, and eventually recovers, one must believe in the curative power of antitoxin. When one sees a patient in whom the intubation tube has been repeatedly clogged, when the hopeless condition of the patient changes for the better after the administration of 50,000 units, one cannot help but be convinced of the importance of giving large doses of antitoxin in the very severe and apparently hopeless cases.[6] The antitoxin service of New York State reports that during 1909 the average dose per lethal case was less than 12,000 units of diphtheria antitoxin.

Diagnosis.—Those who fortunately have had few cases of diphtheria will undoubtedly consider that any discussion of this subject is most uncalled for, and in bringing forward this brief description of symptoms and cases I have no thought of assuming that any of these points are not found in textbooks. My argument is, however, that while these facts are in certain books they are not prominently noted in some and in others they are barely mentioned. Consequently, the physician who has seen but few atypical cases of this disease immediately sums up his knowledge of diphtheria as "an acute contagious disease excited by the Klebs-Löffler bacillus, and characterized by moderate fever, glandular enlargement, great prostration, anemia, and the formation of a false membrane upon certain mucous membranes, especially of the throat and adjacent parts." Together with

this definition the "false membrane" of "grayish color," very "tenacious" in character, "difficult to remove," and "leaving a bleeding surface" are the remaining essential diagnostic points. Without any one or more of these objective symptoms the case is not entitled to a serious suspicion of diphtheria. On the other hand, those particularly interested in the diseases of children will recall Holt's excellent description of this disease; but to others his account of nasal, laryngeal, pharyngeal, and middle ear manifestations of diphtheria will read like a fairy story. The membrane, that oft-mentioned foundation stone, is not seen in many instances. There may be no rapid development of the disease. Two or three weeks may elapse before any very marked symptoms warn the parents and physicians of the presence of a contagious and dangerous disease. What may be noted is a fretful child, gradually becoming weaker and more irritable, with a slight "cold in the head" or with some small degree of discharge from one ear, or a slightly rapid pulse, sometimes irregular and at times surprisingly weak, or perhaps increased respirations, which may be a trifle labored. There may be a little fever each evening or a slight hoarseness. The increasing weakness and gradual loss of appetite seem rather hard to explain to the worried parents. Smears or cultures taken from deep down in the throat or from far back in the posterior nares would prove the presence of diphtheria bacilli, but since the textbook description lays little stress upon any such symptoms, and since the "membrane" is not to be seen, no such diagnostic measure is taken. Later, perhaps, when the child has become terribly weakened by the toxin of the disease, the laboratory may be appealed to. The value of such early laboratory evidence in all suspicious or unexplained laryngeal, nasal, pharyngeal, or aural conditions is well expressed by McCollom.[7] "The importance of a bacteriological examination in all cases of suspicious sore throat cannot be overestimated. Much has been said about the inaccuracy of cultural diagnosis, and, while mistakes may be made in the laboratory, the chances of error are very much less in cultural diagnosis than in clinical. One great source of error is carelessness in taking the culture. The swab is simply put into the mouth and does not come in contact with the membrane." In many instances the cultures are not thought of until the clinical evidences of the disease are so clear that the laboratory report, as well as the delayed use of antitoxin, is valueless. Dr. Dixon, State Commissioner of Health of Pennsylvania, especially comments on these delayed diagnoses.[8] His annual report for 1908 gives a not uncommon example of tardy diagnosis. Dr. M. F. Cawley, C.M.I., after investigating an epidemic in an asylum of thirty-five inmates in Lehigh County, Pa., reports the fact that "the attending physician had not diagnosed the earliest cases as diphtheria and it was only when the child of the superintendent sickened and Dr. S. of Bethlehem was called that the disease was properly diagnosed." Here is an example of late diagnosis which resulted in endangering the lives of some thirty-five persons, mostly children, all residing in close contact. Surely with all of the ample facilities furnished by the State of Pennsylvania, and with sore throat present in several children, one might expect that a few cultures would be taken even if there did not happen to be an enormous membrane in each throat. All statistics prove that deaths from diphtheria are due, in the majority of instances, to delayed diagnosis and to late and insufficient administration of antitoxin. The fact that in the lethal cases occurring in New York less than 12,000 units were administered as an average has already been stated. The following graphic presentation shows the result of delayed diagnosis and treatment. These percentages were compiled from the Pennsylvania health statistics and further comment is uncalled for:

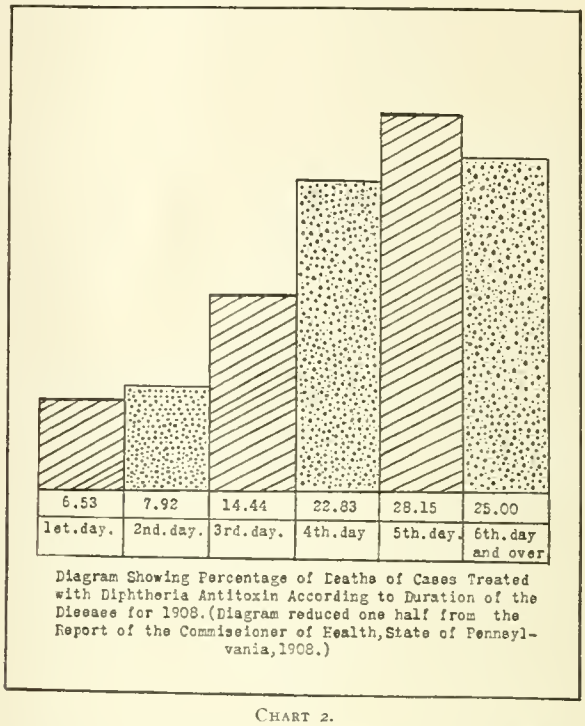

Diagram Showing Percentage of Deaths of Cases Treated with Diphtheria Antitoxin According to Duration of the Disease for 1908. (Diagram reduced one half from the Report of the Commissioner of Health, State of Pennsylvania, 1908.)

Chart 2.

Frequency of Administration of Antitoxin and Amounts Needed.—When we come to consult the various authorities as to the amounts of antitoxin needed and the frequency of its administration, the advice is surprisingly at variance. Quite naturally we would not expect to find the same exactitude in dosage as in well known drugs of many years' use, but after nearly eighteen years one would expect more uniformity in the amounts advocated. Still, as McCollom explains, there is no way of estimating the quantity of toxin generated in any one case of diphtheria and therefore the curative agent must be administered until the characteristic effect is produced—"viz., the shriveling of the membrane, the diminution of the nasal discharge, the correction of the fetid odor, and a general improvement in the condition of the patient." Large doses are not required in the majority of the cases, he asserts, and ordinarily 4,000 to 6,000 units is sufficient to produce the characteristic effect. So we are to administer the antitoxin until all untoward symptoms disappear, no matter whether we use 4,000, 50,000, or 100,000 units. Unfortunately Osler in his textbook does not tell us at what intervals this serum is to be repeated, but leaves us with merely the ranges of dosage up to 50,000 or more, as may be demanded.[9] McCollom, however, in Osler's "Modern Medicine," gives advice as to dosage and interval, which is much more specific. He prefaces his remarks by stating that in the early days of antitoxin the doses were too small because of the legitimate fear of doing harm, but as experience has shown that there are no ill effects from the use of this serum, the dosage has

been materially increased. In cases with a very extensive membrane or very toxic symptoms, he advises 8,000 or 10,000 units immediately, to be repeated every four to six hours until the characteristic effect is produced. Small doses, he contends, are of little avail in the treatment of grave types of this disease, and in order to obtain the best results the serum must be heroically administered.[10]

Ballenger recommends: (a) 2,000 to 3,000 units in ordinary diphtheria to a child over one year old; (b) 3,000 to 5,000 units in severe laryngeal cases of any age; (c) 1,500 to 2,000 units to an ordinary case in a child under one year old." This advice, although appearing in his latest edition, published in 1909, might more properly appear in a volume published ten or fifteen years ago. The time interval between doses is given as twelve hours or less if the symptoms are increasing, and in eighteen to twenty-four hours if there is no decided improvement.[11]

Emery suggests under the treatment of diphtheria that 4,000 to 8,000 units of serum be given at once and a second injection at the end of twelve or twenty-four hours, with subsequent doses given as required. "Larger doses may be given, but are of doubtful advantage; a smaller amount should not be given, except, perhaps, in mild cases." Here again the interval is twelve to twenty-four hours.[12]

One of the antitoxin laboratories advises us as follows: "In light cases, not involving the larynx, if treatment is given early, 2,000 units may be considered the average curative dose; if treatment is delayed, 3,000 units should be given. In severe cases, and especially in croup, the initial dose should be at least 4,000 units, while 5,000 to 10,000 units are often indicated. In cases in which marked improvement does not follow the first dose the remedy should be administered a second or third time, depending upon the symptoms, at intervals of eight to twelve hours." "With refined and concentrated antitoxin, giving a maximum strength in a minimum bulk, it is safer to give large doses than to risk the danger of an insufficient dosage."

Another manufacturing company recommends a therapeutic dose of never less than 5,000 units. "If the disease has progressed for some time" in pharyngeal diphtheria "and the membrane is extensive or is disposed to spread, give at least 10,000 units as a first injection. In all cases of nasal or laryngeal diphtheria—membranous croup—never administer less than 10,000 units. If antitoxin is given late and the symptoms of asphyxia seem imminent, 10,000 to 20,000 units should be promptly administered. In all cases in which a decided improvement is not observed within six to eight hours antitoxin should be administered in at least double the initial dose and continued every six to eight hours until a favorable result is secured."

Since most of our serious cases occur in children, it is particularly fortunate to find that Holt has very decided views on the use of this serum in diphtheria. His very wide experience with this disease in children renders his advice of especial value. "Convinced now of the essential harmlessness of the serum, the tendency everywhere has been to use larger and larger doses, a practice which has been fully justified by the results obtained. For a child over two years of age an initial dose for a severe attack, including all laryngeal cases, should not be less than 7,000 or 8,000 units; repeated in from six to eight hours, provided no improvement is seen. Children under two years should receive from 5,000 to 7,000 units. Cases of exceptional severity in older children should receive from 10,000 to 15,000 units, to be repeated in from six to eight hours if the progress of the illness is unfavorable. Mild cases should receive from 3,000 to 5,000 units as an initial dose, a second rarely being required. In cases receiving antitoxin late, even though the symptoms may not seem particularly severe, the dose should be increased in proportion to the length of the illness, *i.e.* if three days ill, three times the ordinary dose should be given."[13] From this latter advice it would appear that in a very severe case of three days' duration 30,000 to 45,000 units would be indicated as an initial dose. Here, once again, it may be well to recall Dr. Porter's statement, that the *average amount of antitoxin given to those who died from diphtheria in New York State was less than* 12,000 *units.* From this varied advice it would appear that those authorities of the widest experience and in whose judgment implicit reliance may be placed agree that in serious cases of this disease large doses of 10,000 to 30,000 units should be given immediately and repeated every four to eight hours if no satisfactory improvement is noted.

As far as the danger from large dosage of antitoxin is concerned, the State report of Pennsylvania is of particular importance. In the following table for the year 1908 it will be noted that the total dosages of 52,000, 57,000, 63,000, 68,000, and 117,000 units caused no deaths. These cases were undoubtedly serious, yet when the antitoxin was heroically administered the patients recovered. This, if it indicated nothing else, would certainly go far to prove that antitoxin in itself is harmless. (Compiled Statistical Report of Pennsylvania.)

Chart 3.

It is of especial importance to note that, with the early administration of antitoxin and in large doses as recommended by those best qualified to advise, those serious cases receiving from 52,000 to 117,000 units all recovered, and there were no

deaths from sudden heart failure, paralysis or nephritis.

Prophylactic Treatment.—For prophylactic measures various authorities agree as to the necessary dosage, although even here there is a tendency to increase the amount from 100 to 500 units as was formerly advocated to 1,000 units or more. Dr. Dixon advises "never less than 1,000 units"; the Mulford Company, 1,000 units; the Lederle Laboratories, 1,000 units; Holt, 100 to 1,000 units on a basis of age: 1 month, 100 units, ten to twelve years, 700 units, fourteen years, 1,000 units; Children's Hospital, Boston, 750 units for those under two years of age, 1,500 units for those of two years or over. In discussing immunization as a preventive measure, Commissioner Dixon lays great emphasis on the fact that "if physicians would follow instructions in regard to immunizing all those in the immediate vicinity of the patient at once, it would go far toward stopping the spread of the disease, if not altogether eliminating the chances of an epidemic." His report for the year 1908 shows that 3,920 patients received immunizing doses, among whom forty-five contracted the disease and only eight died. No record is given as to the time when the immunizing treatment was given, and it is perhaps possible that the eight deaths were due to late prophylactic administration of the antitoxin.

Selection of the Place for Injecting Antitoxin.—This subject is one that should merit but little attention. The important thing is to give sufficient antitoxin early in the disease and as frequently as demanded. Many recommend the region between the shoulder blades. In children this location is excellent because the patient does not see the operation and is consequently not greatly alarmed. Others suggest the arms, legs, or thighs as being preferable. In adults I have usually selected the arm. McCollom especially recommends the back near the angle of the scapula. He advocates this location because the tissues are lax and because if an abscess is caused pus has small space in which to burrow. He particularly warns against the thighs, legs, or arms and states that injections into the abdominal muscles are inadmissable. He argues that the tissues of the arms, legs, and thighs are tense, that the presence of the serum gives great discomfort, and that an abscess in these regions may cause serious trouble. His reason for not using the abdominal region is that such injections cause pain. But in children there seem to be several reasons why antitoxin should not be injected into the arms, legs, back, or thighs. If we use the scapular region, the child is awakened or made uncomfortable if it happens to roll over on its back during sleep. Likewise in turning in bed a sore leg or arm gives considerable pain. Also the leg or thigh becomes so painful after one or more injections that a new spot must be selected. In one of my first cases I recall using first the back, then the thighs, and finally the arms. One injection seemed to produce so marked a degree of swelling (5,000 units was the usual dose at an injection) that it was almost impossible to use the same spot again. Since then I have used the abdominal region. The child naturally lies on its sides or back, so that a tender abdomen causes little discomfort. Also, this area seems to be decidedly less sensitive, and I have given twelve or fifteen injections over the rectus abdominalis muscle without any degree of pain. As far as the effect on the child of seeing the operation is concerned, discussion may be avoided, because it is a simple matter to cover the child's face with a towel if it is particularly nervous. But the greatest advantage of using the abdominal region lies in the fact that we do not have to raise the patient, the part is easily exposed, and a small dressing is sufficient. Abscess formation following the aseptic administration of antitoxin which has been properly prepared is so rare that this factor should assume but little importance in selecting the location. The puncture can be quickly and aseptically sealed with sterile absorbent cotton and collodion.

Treatment Aside from Antitoxin.—All textbooks clearly outline the treatment of diphtheria in so far as nourishment, stimulation, and attention to the bowels are concerned. Emphasis might, however, be laid on the fact that any unnecessary disturbance of the patient is exceedingly harmful. For this reason, in one of the cases cited later, it may be noticed that no temperature record was made for several days. Drastic nasal douching and spraying are being abandoned to a great extent on account of the many instances in which such methods have spread the disease to uninfected areas. If otitis media should ensue, the tympanic membrane must be immediately incised. Should intubation become necessary, the majority of books on practice and surgery, especially Ballenger, give most concise and clear descriptions of the operation. Local treatment is of secondary importance. All of the diphtheria bacilli are not destroyed by the use of the swab and bacteriocidal solutions and the remaining virulent bacteria are prone to attack areas which have been inflamed and injured by injudicious local applications. The real treatment for the disease has been conclusively proved to be antitoxin, given early, in large doses when necessary, and at frequent intervals.

Report of Cases.—The following cases have been selected in order to give a brief survey of the more frequent typical and atypical forms of diphtheria and to indicate what latitude is demanded in the dosage of antitoxin. The first two cases show the usual "textbook" symptoms; the other three may be of interest to those who have met but few of these atypical forms of this disease. Three of the patients showed absolutely no membrane and had no throat symptoms of any importance. In one of the slow developing cases the virulence of the diphtheria bacilli was manifest at the autopsy of the animal into which they were experimentally introduced. It is from cases of this type that epidemics arise, and it is in these slowly developing forms with their origin in the rhinopharynx, Eustachian tube, or middle ear that large amounts of antitoxin are demanded. It is impossible as well as inadvisable in the case of a weak, nervous child to swab these places where the toxin formation is continuing. Our only hope lies in large doses of antitoxin, repeated at short intervals if demanded, a sustaining diet, if possible, and a trust in Providence and stimulation to increase the child's resistance to a point where it can of itself destroy the diphtheria bacilli.

Case I.—J. H., age 4½ years, July 28, 1909. This child, according to his parents, had been restless, irritable, and "feverish" for two nights previous to my being called in attendance. Physical examination and personal and family history were negative except as follows: Temperature 101.6°, pulse 110, respirations 28, complains of no pain in

swallowing, but upon examination a few grayish patches were evident on the tonsils, together with a small degree of tonsillar swelling. Cervical glands, posterior, slightly enlarged, and some slight amount of discomfort was experienced when pressure was made externally over the tonsils. In swabbing the throat for a cultural examination the swab was slightly discolored with blood. Cultures and smears demonstrated the Klebs-Löffler bacilli, together with other bacterial flora common to the throat. At 8 P. M., of the same date, 5,000 units of antitoxin was administered, the injection being made in the tissues over the rhomboid muscles. At 4 A.M., July 29, I was called and found that the rectal temperature was 104.2°, although the child was in a profuse perspiration. Because of the rapid pulse rate of 134, another 5,000 units was immediately given. Five hours later, when I again saw the child, the temperature was normal, the breath was clear of odor, tongue clean, and the child was anxious about breakfast. There was no subsequent rise in temperature on that or the following day and the pulse remained between 80 and 86. No further medical attention was necessary. Part of this temperature of 104.2°, which occurred at 4 A. M., was due, I believe, to the location used for injection. The child would fall asleep and then turn over on his back and suffer considerable pain.

This case might be considered as a slight but usual attack of diphtheria. An early diagnosis and a seemingly large dosage of antitoxin, 10,000 units, administered within eight hours as an interval, resulted in a rapid subsidence of all symptoms with no recurrence and complete recovery.

Case II.—R. F., private, Co. C, 24th Infantry, U. S. Army, November 7, 1910. This man came to the post hospital on the morning of November 7, 1910, complaining of a sore throat which had given him increasing pain for three days. He had no appetite, felt weak and stated that he had had chills. He has had a headache, been nauseated, and has eaten nothing for two days. Physical examination and personal history negative except that he has had frequent attacks of tonsillitis. The man is strong and muscular, eyes are feverish, tongue coated, lips swollen, breath foul, posterior cervical glands swollen, breathes through his nose easily, throat over the region of the tonsils is swollen and has an extensive grayish membrane over most of the pharynx. Swabbing for a culture examination produced a slight bleeding when the membrane was removed. Temperature 102.4°, pulse 96, respirations 24-28. Smears and the later cultures showed diphtheria, as could be readily guessed from this "textbook" history. Five thousand units of antitoxin were administered within two hours after his entrance into the hospital. The throat was swabbed with 90 per cent. silver nitrate once, as recommended by Ballenger in these acute conditions; cold cloths were applied to the neck and a cathartic given. In three hours the temperature fell to 100.2°, and within twelve hours to 99.0°, and the pulse dropped to 72 and the respirations to 20. The membrane had disappeared, the swelling had subsided to a great extent, and the patient could take semi-solid food with comfort. Recovery was uneventful. The urine was negative during and after the disease.

In this patient we have a strong, vigorous man suffering from a simple tonsillar and pharyngeal diphtheria. Five thousand units was ample to cause a cessation of all symptoms, and since this is the guide to dosage, only 5,000 units were given.

Case III.—Ellen K., age 3¾ years, July 27, 1909. For two weeks previous to my seeing this child there had been an eruption on the lower part of the face, more especially prominent on the upper lip, and a very offensive, although slight, catarrhal discharge from the nose. The eruption was considered as a possible ivy poisoning, and the nasal condition was thought to be a rather persistent "cold in the head." Toward the end of these two weeks, however, the child became restless, very irritable, slept poorly and seemed surprisingly weak, although at no time had this weakness become so marked as to demand absolute rest in bed. There had been a gradual loss of appetite and an evening rise in temperature of from one to two degrees. On July 27, when I first examined the child, there was a slight attack of vomiting and several fits of sneezing. This latter symptom had been present for three or four days, according to the statements of the parents. While examining the child's nose a very severe attack of sneezing occurred and resulted in a somewhat prolonged epistaxis. This bleeding brought with it some curious clots and bits of tissue, which were preserved and taken to the laboratory for cultural examination. The odor from this discharge was almost putrefactive in character. The mucosa of the nostrils presented evidences of some inflammation, although no membrane was noted. The left nostril was partly occluded. The lips were swollen and excoriated, especially the upper one, on which were many yellowish crusts, suggesting previous pustules or vesicles. The throat was slightly reddened, but there was no evidence of any membrane nor of any necrotic spots. There was and had been no difficulty or pain in swallowing. The child's cheeks were flushed and her appearance was listless, although when a swab was made from the throat and nostrils a marked and prolonged hysterical outbreak occurred. This, in turn, was followed by a period of complete relaxation, as if the child was terribly weakened. The temperature at 8 P. M. of this date was 102.3°, pulse 132, and respirations 30. The cervical glands were swollen and painful on pressure. Urine, reddish orange in color, S.G. 1.031, acid in reaction, offensive in odor with a decided trace of albumin and a few hyaline casts together with large amounts of amorphous urates and phosphates but no sugar. Blood examination: Reds, 4,120,000; whites, 14,000; Hb. (Sahli), 63 per cent. Fecal examination made later was negative. Bacteriological examination of the nasal secretion showed diphtheria bacilli, staphylococci, and large diplococci, while the throat cultures and smears showed no evidence of diphtheria. The discharge from the nose, aside from the bacteriological content, demonstrated microscopically pus cells in large numbers; red blood cells, shreds of degenerated mucosal tissue, and minute portions of what may have been membrane. At 5 P. M., on the 28th, 5,000 units of antitoxin were given. Within four hours there was a fall in temperature from 102.6° to 100.0°, and the pulse dropped from 132 to 94. The child was resting quietly, breathing through its nose and the odor of the breath was less offensive. At 9 A. M. of the 29th, 3,000 units more were administered, and by 6 P. M. of that same day the temperature fell to below normal; the pulse was 80, and all discharge from the nose had ceased. The odor of the breath was no longer foul and air passed freely through both nostrils. Within two

days thereafter the child was entirely well, as far as pulse, temperature, respirations, and the discharge from the nose were concerned. All swelling and excoriation of the lips had disappeared also. Cultures from this time on were negative for diphtheria, and the child has since been perfectly well. To ascertain the virulence of a diphtheria organism which was so slow in its toxic formation, a pure culture of this particular strain was introduced into a healthy cat. In two and a half days the cat died. At autopsy the throat was found to be inflamed and the tongue so swollen that only after probing could air be forced into the lungs. The mucosa of the trachea was covered with a thick detritus which, when forcibly removed, brought away with it large layers of the epithelium. The lymphatic glands all over the body, but especially in the cervical region, were greatly swollen. Cultures from the trachea and bronchi showed the diphtheria bacillus in almost pure culture.

Judging from this case, it is quite probable that this child had been suffering from nasal diphtheria for at least ten days. The virulence of this strain of bacillus was possibly not great and consequently there were no very marked symptoms. The probable results of a later administration of antitoxin may be surmised from a survey of the next case. Probably the child would have had an extension of the inflammatory processes into the rhinopharynx, larynx, or ear. During these ten days of her illness this child was an actively infectious case and only the fear of the parents that she might "catch more cold" kept her indoors and from contact with other children. Even with her remaining indoors, however, case No. 1 was traced directly to having visited this girl during the beginning of her sickness. That this child would have been a most excellent agent for spreading the infection and starting a serious and perhaps fatal epidemic can well be imagined, when after a comfortable existence in the throats of other children the virulence of the bacilli had been sufficiently increased.

Case IV.—Virginia F., age 3¾ years, October 16, 1910. On the evening of October 16 I was called in to see this child and found that she had a temperature of 103.0° and a pulse of 120. Her face was flushed and her mother stated that the child had been suffering for a day or so with a slight sore throat. Upon examination the throat showed an inflamed area over the tonsils and uvula, and there was some swelling in these regions. I made a culture, swabbed the throat with 20 per cent. argyrol and left some medicine for tonsillitis. I also directed cold applications for the neck if there was marked distress, and upon leaving stated that I would return in the morning. This seemed from the rapid development and the high fever with few if any constitutional symptoms to be a case of tonsilitis, to which the child was subject. Cultures made on this date were negative.

October 17. Upon calling in the morning I found that the child was out of doors playing, and the mother reported that the fever had disappeared and that the throat seemed well. At about 8 P. M. of the same day I was again called to see the child, and found practically the same condition as had existed on the previous night. Physical examination revealed a strong child, vigorous and well nourished. The family and personal history had no bearing on the case. With the addition of a purgative, the same treatment was advised as on the evening before.

October 18 to October 29. During this interval of ten days I was away from the patient on leave and did not see the child until the night of the 29th. On this date I found that a most distressing change had occurred. She had lost a most appreciable amount of weight. Her eyes were feverish, the lids were swollen, the face was pale with now and then a deep flush, and her cheeks showed great emaciation. The throat symptoms had increased during my absence, and the parents reported that there had been a daily fever, no appetite, and frequent hysterical outbreaks during which the father had considerable difficulty in holding the child. Rather drastic douching and spraying of the nose and throat had been resorted to on the advice of a physician, and to this treatment is due the extensive involvement of the throat, nose, ears, and Eustachian tube. Upon examination a purulent, foul-smelling discharge from the right ear was noticed, the breath was so offensive that upon entering the room the odor was immediately detected, the tongue was swollen and heavily coated, and crusts were observed in the nostrils. The throat was greatly inflamed and painful. No membrane was apparent. Fever had been persistent for ten days past, and although the child seemed half comatose and mentally indifferent to her surroundings, as soon as an attempt was made to introduce a thermometer into the mouth, rectum, or axilla the child became convulsed and shrieked until exhausted. This was not due to poor training, because many times before I had taken the temperature by mouth and also examined the throat without any such difficulty or unpleasant results. Judging from the surface temperature, the thermometer would probably have recorded somewhere about 103.0°. The pulse was rapid, very irregular, and weak, and averaged between 150 and 160. Major Henry S. Greenleaf, Medical Corps, kindly consented to see the patient in consultation, and the diagnosis of diphtheria was considered as probable on the clinical evidence. A smear was made from the throat, rhinopharynx, and from the discharge from the right ear. Diphtheria organisms were found in each of the specimens taken and cultures verified the findings of the smears. Antitoxin was obtained as soon as possible, and on the evening of October 31, at 6:45, 5,000 units were given. In two hours the child was drenched with perspiration and fell into a quiet sleep—the first continued, restful sleep that had been noticed in two weeks.

November 1. The child became hysterical during the evening of this day and at 7:45 P. M. another injection of 3,000 units was given. There was some difficulty in breathing, the discharge from the ear continued, but the odor of the breath was less offensive and the temperature remained lower. The pulse was regular although rapid. November 2. The odor of the breath was less offensive, there was less discharge from the ear and none from the nose. The throat still remained swollen. Pulse 110-120, weak but regular. November 3. The temperature rose during the afternoon to what seemed to be 103.0°, pulse 155, regular but exceedingly weak. Examination of the left ear showed a bulging and reddened ear drum. This was incised and a purulent discharge escaped. Diphtheria bacilli were found in the discharge. The urine was dark reddish brown, with a decided odor, specific gravity 1.029, acid in reaction, no sugar but a large amount of albumin and a few hyaline and granular casts; 4,000 units of antitoxin given. No-

vember 4. The temperature seemed more nearly normal, pulse less rapid, odor had disappeared from the breath, the tongue was no longer swollen, and the lips had assumed a normal size. The child had begun to take small amounts of ice-cream and when thirsty was compelled to drink milk diluted with lime water. November 5. The temperature was high during the evening, but the pulse was slower, averaging about 130, and was of better quality than on other evenings. The ears have ceased discharging and the boracic solution used as a wash returned clear of any pus; 5,000 units were given. Feeling that any temperature or increased pulse rate might possibly be due to secondary invaders, and having in mind the excessive cost of antitoxin, none of this serum was administered for four days. The throat was cleansed daily, bowels moved, etc. The breath remained clear of odor and the temperature dropped to about normal and the pulse rate was 92, full and was fairly strong. November 10. At 7:45 P. M. the child had a serious hysterical outbreak with spasms of the muscles and a marked delirium. The temperature had increased to 102.3°, pulse 160, weak and irregular, and respirations 40-50 to a minute; 3,000 units of antitoxin were given. One hour afterward the child became quieter and slept fairly comfortably during the night. The pulse dropped to 120, temperature to nearly normal, and respirations to 31. November 11, At 4:30 P. M. there was a return of the symptoms as on the former evening; 4,000 units of serum were given immediately. A subsidence of symptoms ensued. At 7:30 of the same evening the temperature and pulse again rose, and the child became very restless; 3,000 units more were given. November 12, 5:30 P. M. The pulse again became rapid, discharge from the ears returned, and smears again revealed the diphtheria organisms. Clots of blood came from the nose; 5,000 units of antitoxin were given.

It immediately became apparent that this was a case of insufficient amounts of antitoxin, and that the child, without the aid of enough of this serum, was not strong enough to cope with or kill off the bacteria which were secreted in the middle ear, nose, and pharynx, and which during the administration of the serum did not disappear but merely showed no toxic symptoms. As can be well imagined, the child was growing weaker. From this time on I determined to give antitoxin until all symptoms had disappeared and remained so. Accordingly, November 13, 5,000 units were given. This resulted in a lessened discharge and a pulse rate of 128. The child seemed better. November 14, 5,000 units administered at 8 P. M. Pulse slower, no discharge from ears, appetite returning, temperature normal by thermometer. November 15, 5,000 units given. Child had no fever, pulse 82, respirations 20. Appetite was excellent, child began to gain strength, and pulse is full and strong. November 25. The child has been out of doors in a carriage, but has not been allowed to exert herself or exercise in any manner. December 3. The child has completely recovered, is as strong as ever, her heart action is normal, pulse 80-90, of very good quality, urine normal, and she has regained all of her lost weight. *Amount of antitoxin used,* 47,000 *units. Result, recovery.*

In Case III the inflammatory condition, although of long duration, was limited to the nostrils and a small portion of the rhinopharynx. Eight thousand units were sufficient. But in this last case there was an immense area over which the diphtheritic condition held sway, enormous amounts of toxin were being formed, and, theoretically at least, a proper treatment would have indicated a dosage of 10,000 units immediately with subsequent doses of at least 5,000 units at intervals of four to six hours until every symptom had subsided and remained so. Among these symptoms I believe that the pulse and the general condition and appearance of the patient are the most important. As McCollom emphatically states, the antitoxin should be administered till there is a shriveling of the membrane (if there be one), a diminution of the nasal discharge and a *general improvement of the patient.* It there be no membrane, then we must depend upon the cessation of a nasal or aural discharge, a return to normal pulse rate and temperature, and a general improvement in the condition of the patient. Such a treatment would, I feel sure, have resulted in a more rapid recovery, and in the end less serum would have been used. But, as has been previously noted, the cost of antitoxin is so excessive that a physician does not care to give this serum except when absolutely demanded. The life of that child was seriously endangered by withholding antitoxin during those days cited. Yet there was a possibility that the symptoms at that time might be due to some other cause. With such a possibility there was a delay for proof that the serum must be given. Had death intervened before the readministration of antitoxin would not the diagnosis in this case have been that of "heart failure"? This diagnosis would have been correct; only to be more explicit the heart failure would have been due to the poisonous effect of the diphtheria toxin on the nervous system and whole body. To be yet more explicit we would have had to note that the direct cause of this was that the toxin was not sufficiently neutralized with antitoxin.

Case V.—Helen N., aged 3¼ years, December 17, 1910. Family history negative, except for rheumatism. Personal history: General health has been good until four months ago when the child was attacked with a general skin disease which from clinical evidence proved to be dermatitis exfoliativa. This skin disease began on August 15, 1910, with a scaling of the hands and feet which gradually spread over the entire body. At times there has been a slight rise in temperature associated with the disease, but not for several weeks previous to the present attack of diphtheria. On December 17 I was called in for the first time to see the child and found her suffering from a pain in the right ear and a slight diarrhea. The ear was examined and a foul discharge, small in amount, was discovered. This discharge was tinged with blood, but a bacteriological examination revealed only a few staphylococci, some pus cells, and a very few red blood cells. Upon physical examination the patient was seen to be anemic, rather weak, and poorly nourished. The whole body was covered with silvery scales which were readily removed and left a reddened thickened epithelium. Examination was otherwise negative except for an afternoon temperature of 100.4° (rectal), pulse 112, and respirations 25. There was no discharge from the nose, the conjunctivas were clear, and the throat was only slightly reddened. A culture was made but no evidence of diphtheria was found.

December 18: The patient has been restless and feverish. After a cleansing with boracic acid solu-

tion the ear has stopped discharging and there is no more pain. The child has no appetite and will take no nourishment. The lungs are clear except for a somewhat prolonged expiratory murmur. The diagnosis is undetermined because of the following possibilities: an exacerbation of the dermatitis, a beginning by lobular pneumonia, an acute indigestion, typhoid fever, mastoiditis, or diphtheria. The throat is very slightly reddened, but there is no pain in swallowing and the larynx appears clear. The posterior cervical glands are enlarged. Toward evening a vomiting attack occurred. All temperatures are rectal in this case. Temperature 100.4°, pulse 128, respirations 28. December 19, 9 A.M.: T. 101.2°, P. 124, R. 24. Cultures were made from deep in the larynx and from the pharynx and nostrils. The patient seems weaker, more restless, and quite irritable. 8 P.M.: T. 102.6°, P. 142, R. 33. Another vomiting attack occurred late in the evening December 20: Cultures taken from the larynx showed diphtheria bacilli. Antitoxin has been ordered. All day the child has become progressively worse. Nine A.M.: T. 101.8°, P. 130, R. 33. At 4 P.M. the child is languid, pays little attention to surroundings, and rests with eyes half open. The breathing is noisy. T. 104.4°, P. 145, R. 38. Pulse is irregular and weak, and the child is aroused with great difficulty. 6.30 P.M.: The child is lying with eyes partially open, cannot be aroused, the lips are swollen, cracked, and bleeding near gums, the mouth is open and a rattle is heard as short, shallow whistling breaths are taken. The throat shows a reddened area, but no membrane is apparent. The breath is very offensive. Antitoxin arrived at this time and 5,000 units were immediately given. The child did not notice the injection. Breathing is becoming even more labored. T. 104.8°, P. 158, R. 48. 7.30 P.M.: Another 5,000 units given. T. 104.6°, P. 163, R. 68. The pulse is so weak that it is necessary to use a stethoscope to count the heart beats. Breathing has become more difficult. The intubation set and an assistant have arrived and are ready if needed. Fifteen centimeters of whiskey are given. Feces and urine are passing involuntarily. There has been a slight attack of vomiting. Nine P.M.: 4,000 units of antitoxin are given. There seems to be a slight improvement. T. 103.4°, P. 153, R. 48. Breathing seems a trifle less labored. The child remains, however, in a comatose condition. The eyes remain partially open, and the eyelids have not moved for more than an hour. No movement was made during the injection of serum. There is another movement of the bowels involuntarily. Urine is passing at intervals. Twelve M.: There seems to be a great improvement, the pulse aside from its being slower is a little less weak. Perspiration is noticed over portions of the body. T. 102.4°, P. 130, R. 38; 2,000 units administered. December 21, 4 A.M.: The child is sleeping, can be aroused, and is able to open her eyes. Whispers and answers questions. T. 101.4°, P. 98, R. 27. Nine A.M.: T. 101.2°, P. 114, R. 38. The pulse is more rapid and is irregular and weak; 10,000 units of antitoxin given. Four P.M.: T. 102.6°, P. 142, R. 48. Pulse has increased in frequency and is exceedingly weak. Whiskey is given. The bowels are moving involuntarily; 4,000 units of antitoxin are administered. Eleven P.M.: T. 100.0°, P. 102, R. 28. Patient seems better. The child has been taking some milk, diluted with lime water, into which were put one raw egg and some whiskey. This is given whenever the child demands a drink of water. All liquid is given in this form. December 22—The child is at times crying and while asleep is restless. Involuntarily micturition is reported by Miss Benson, the nurse in charge. The pulse is rapid, irregular, and weak. A yellowish discharge is noticed in both eyes and proves to be diphtheritic. The bowels have been moved by enema with a resulting foul smelling movement. Nine A.M.: T. 102.6°, P. 134, R. 38. At 8 P.M. T. 103.4°, P. 138, R. 44. Five thousand units of antitoxin are given. December 23—The child is able to speak clearly for the first time in two days. The respirations are a little labored still. The pulse, however, is strong and regular. The patient is taking considerable nourishment in liquid form. Nine A.M.: T. 99.0°, P. 84, R. 23; 8 P.M., T. 100.8°, P. 88, R. 23. December 24—Nine A.M.: T. 100.4°, P. 82, R. 20; 8 P.M., T. 101.4°, P. 89, R. 26. The pulse is full and strong. The respirations are no longer labored. There is no more involuntary urination. The bowels are under control. The discharge from the eyes has ceased.

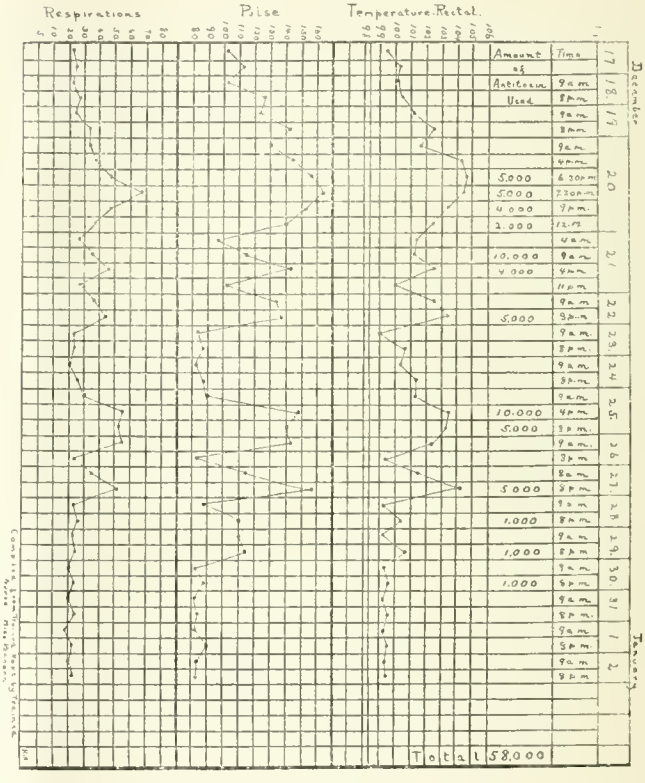

CHART 4.—Case 5, showing temperature, pulse rate, respirations, date, time, and amount of antitoxin used. Total amount used, 58,000 units.

December 25, 9 A.M.: T. 101.4°, P. 90, R. 30. During the morning the child has been cheerful and has taken considerable nourishment. The pulse is not quite as strong and shows a tendency to irregularity. Four P.M.: T. 103.6°, P. 149, R. 55. The child has become restless, there is some delirium, the respirations have become shallow and rapid, and the breathing is noisy. Ten thousand units of antitoxin are given at once. Eight P.M.: T. 103.2°, P. 140, R. 53; 5,000 units more given. December 26—During the past night the child slept well, and the nurse reports that at one time there was a marked perspiration. The child slept most of the day and none of the restlessness so noticeable at other times was observed. The pulse is slow and regular, breathing is deep and noiseless. Nine A.M.: T. 102.4°, P. 142, R. 55; 8 P.M., T. 99.4°,

P. 83, R. 22. December 27—8 A.M.: T. 101.4°, P. 114, R. 34; 8 P.M.: T. 104.2°, P. 158, R. 52. There is considerable noise in breathing, the pulse is weak and there is considerable restlessness with attacks of crying; 5,000 units of antitoxin given at 8 P.M. December 28—9 A.M.: T. 99.4°, P. 88, R. 23; 8 P.M.: T. 100.4°, P. 110, R. 25. One thousand units of serum given. Patient has taken forty ounces of milk with two raw eggs during the day. December 29—9 A.M.: T. 99.4°, P. 110, R. 22; 8 P.M.: T. 100.8°, P. 114, R. 23. One thousand units given. There has been a slight urticaria from the antitoxin. December 30—9 A.M.: T. 99.4°, P. 82, R. 20; 8 P.M.: T. 99.8°, P. 89, R. 23. One thousand units given. There was a normal movement of the bowels to-day, without the usual enema. December 31—9 A.M.: T. 99.2°, P. 81, R. 20; 8 P.M.: T. 99.6°, P. 83, R. 23. The child seems well, is regaining strength and weight.

January 1, 1911—9 A.M.: T. 99.2°; P. 82, R. 18; 8 P.M.: T. 99.6°, P. 90, R. 22. The child is very hungry; nothing abnormal is noted. January 2—9 A.M.: T. 99.4°, P. 83, R. 20; 8 P.M.: T. 99.6°, P. 84, R. 22. January 14—The child has been out of doors and is completely over the diphtheria. She is regaining weight and the skin disease seems better. The heart is normal, and the urine which on December 20 was dark red in color, s.g. 1.033, neutral in reaction, with a decided trace of albumin and some casts, is now normal. *Total number of units of antitoxin used* 58,000. *Result: recovery.*

Summary.—1. The high death rate from diphtheria may be traced to the following factors; late diagnosis, late or inefficient prophylactic measures, lack of faith in antitoxin, and insufficient dosage in serious cases.

2. Cases diagnosed early demand from 3,000 to 5,000 units immediately to be followed by a further administration of 5,000 units or more in from four to six hours if there is no improvement. Cases diagnosed late, or those of a serious laryngeal character, or those showing especially toxic symptoms as indicated in the general condition of the patient and in the quality and rate of the pulse, should receive from 10,000 to 30,000 units immediately, and this dosage should be repeated at intervals of four to six hours until there is a complete subsidence of symptoms.

3. All of those in contact with diphtheria patients, or those suspected of such contact, should be given at once an immunizing dose of 1,000 units of antitoxin.

4. All statistics indicate that there is no danger to the heart, kidneys, or nervous system from very large doses of antitoxin. The danger to the patient lies in using insufficient serum.

In conclusion, I wish to express my appreciation for assistance and data to Dr. Eugene H. Porter, Commissioner of Health of New York; Dr. Samuel G. Dixon, Commissioner of Health of Pennsylvania; Dr. Mark W. Richardson, Secretary of the State Board of Health of Massachusetts; Dr. C. W. Rohrer, Assistant Chief of the Department of Health of Maryland; Colonel Walter D. McCaw, U. S. Army, Librarian of the Library of the Surgeon-General; Dr. Joseph Adna Hill, Chief Statistician of the Census, and Miss M. L. Benson, the trained nurse in charge of the last reported case.

WHAT IS RHEUMATISM?*

By HERBERT C. DE V. CORNWELL,

NEW YORK.

THE term "rheumatism" is a most loose one and extremely unsatisfactory. It was originated at a time when the true nature of the disease was less accurately understood than at present and was based upon an entirely false conception of its cause. It is now used indiscriminately to describe a symptom and the actual disease, also to cover our ignorance of some unknown condition; likewise to signify diseases that have nothing in common with rheumatism except a similarity of symptoms, as, for example, tuberculous rheumatism, gonorrheal rheumatism, when it would seem far more appropriate to use the word arthritis. I think it would be also more in keeping with our idea of the real nature of the affection to speak of rheumatic arthritis, rather than articular rheumatism, in the same manner that we speak of rheumatic endocarditis. It seems that education and custom as well as the psychological influence of misapplied terminology have taught us to look upon it primarily as a disease of the joints, regarding other manifestations as so-called complications, when, as a matter of fact, they are rather coordinate expressions of an identical process, for it bears all the earmarks of a constitutional infection and upon this view we should insist.

The onset is acute and febrile, the course a definite one, as a rule, and self-limited, and it is characterized by a general intoxication with local manifestations in the tonsils, joints, muscles, endocardium, pericardium, or, to a less frequent degree, other serous surfaces and tissues. We are struck by its similarity to other infections of germ origin, and, in spite of the advocates of the lactic acid theory or other metabolic causes, most men to-day are inclined to the thought that it is caused by a specific germ; and, indeed, we have fairly good scientific support for the application of the germ theory. Excellent observers, among them Poynton and Paine, have made extensive experiments for the identification of the infective agent, and have isolated an organism to which the name *Diplococcus rheumaticus* has been given. This germ they have isolated from practically all the tissues that are subject to clinical evidence of the disease, including the tonsils, and in the case of chorea from the cerebrospinal fluid. This relationship between chorea minor and rheumatism is a most important one, long suspected on clinical grounds, and practically proven on a scientific pathological gasis. The germ has been grown on broth cultures and has been injected into a large number

*Read before the Medical Association of the Greater City of New York, January 16, 1911.

of rabbits, with the production of all the essential symptoms of rheumatism, including arthritis, endocarditis, and even chorea. It is hardly probable that the infection is a mixed one or an expression of a mild pyemia caused by one of several varieties of pyogenic organisms, though this view has been held by good authority and is still adhered to by many. But it seems that the clinical symptoms are too fixed in spite of their classic variations. These same observers have experimented with pyogenic germs, but the results in rabbits were on the whole so different from those obtained with the supposed specific organism that few are now inclined to doubt the etiologocal influence of the *Diplococcus rheumaticus*. A further argument in favor of this diplococcus is the production from it of a vaccine, which by comparison with vaccines from other organisms in the treatment of the disease shows a percentage of cures far too high to be ascribed to natural causes. While everything is in favor of this theory, little can be urged against it but the considerable difficulty of isolating the germ.

The channel of invasion is a matter of no small interest. The existence of tonsillitis before and during systemic attacks in about 20 to 25 per cent. of the cases is a strong argument in favor of this site as a focus of primary infection. Whether all cases of rheumatism arise by way of the tonsils, in which event many infections must of necessity occur without subjective symptoms, or whether there is another as yet undiscovered passage of entrance is still a matter of active debate. In any case, the appearance of the tonsils when inflamed is so characteristic that ordinarily a diagnosis of the disease may be made from their appearance alone, and that, too, in the absence of other constitutional phenomena. That this close association between tonsils and rheumatism really exists is indicated by the fact that individuals subject to repeated attacks of the disease are more apt to be free after removal of the tonsils, while those with normal, healthy looking tonsils are less subject to attacks than are those in whom these glands are soft, congested, and spongy. But the tonsils give us another and equally interesting sidelight on the habit of the rheumatic infection. Histologically they are lymphatic glands and are intimately connected with that part of the lymphatic system with which they are related. The disease finds its favorite expression in serous and synovial membranes and in the lymphatics of muscles, and while the endocardium may not be a lymph space histologically, yet it is my belief that lymph spaces within the musculature of the heart are in close relation with its lining membrane. This observation rather tempts us to regard rheumatism as a disease of the lymphatics. If we do, it will simplify our understanding of its distribution very materially. It will make it possible for us to perceive more readily the relation existing between tonsils and the foci of distribution and between synovitis and pericarditis. But even if this is so, our understanding of the laws underlying the habit of rheumatism is still far from complete. The matter of localization brings up the issue as to why certain joints or tissues are more frequently invaded than others; the big joints rather than the small ones, or the endocardium more frequently than the pericardium, and the latter more often than the pleura.

These questions we must for the present relegate to the unanswered problems of the disease. We can only state the facts of clinical observation, that as to relative susceptibility of joints or endocardium children will suffer frequently far more acutely from throat, constitutional, or cardiac disturbance and show, perhaps, only a transitory inflammation of the articulations, and often none at all, while in adults the arthritic phenomena are more striking and more frequent, with a diminution of heart disturbances directly proportionate to the age of the patient. This most interesting circumstance, evidently due to physiological idiosyncracies, inherent in the quality of age, may indicate a greater resistance of joints to morbid invasions by virtue of a more active cell-proliferation during the early years of life, though such a theory could, in the light of present knowledge, be regarded as little more than speculation. There is no question but that children are more susceptible to the rheumatic infection than is generally supposed; they are a patient and long-suffering class. They make little of disturbances that would cause the adult great concern, and frequently the mere existence of hyperpyrexia passes unnoticed or is ignored by the parent as inconsequent, particularly if merely transitory, though it may be a true case of rheumatic fever which, even if only of a mild nature, may be followed by local developments of the most serious kind. And it must be admitted that the doctor, too, when called to see such a patient with perhaps no focal symptoms and no other signs upon which to base the probability of any given disease, may often prescribe for intestinal indigestion with castor oil, since his failure to recognize its possible rheumatic nature is due to the mental habit of diagnosing it on the basis of joint symptoms almost exclusively; an unfortunate habit, as the focal symptoms appearing later may be as severe and lasting as if the febrile attack had been profound and prolonged.

For a long time acute clinicians had observed a certain close relationship between chorea minor and rheumatism; patients who exhibited coincidently the symptoms of both diseases or suffered from them alternately. As a rule, chorea associated with rheumatism is more apt to declare itself as the acute symptoms subside. So constantly have the heart manifestations coincided even in the absence of more scientific confirmation that one might easily have been tempted to apply the mathematical maxim that things equal to the same thing are equal to each other, and that rheumatism and chorea are etiologically identical. But nature will always fulfill the promise of genius. The fact was brought out earlier in this paper that in cases of chorea minor diplococci apparently the same as those of rheumatism had been isolated from the cerebrospinal fluid. If we grant the common etiological factor, no compromise with our conscience is necessary to concede the relationship, and we are placed in the strong position of having an organic basis upon which to study and explain the symptomatology of what had until recently been considered a functional nervous disease. These diplococci are supposed to produce the expression of chorea by causing a mild leptomeningitis and if, indeed, they invade this territory, the incoordinate and purposeless twitchings, such as we get in chorea minor, are just what one might expect from mild meningeal inflammation.

The germ theory has been and is still denied by not a few authorities whose opinions cannot be lightly passed over; some of them indicating with great force the influence of diet in treatment in predisposing to or even bringing on attacks. We cannot deny the relationship of nutrition to rheumatism, and, I believe, can explain it away in no other man-

ner than by the assumption that the germ finds its most favorable soil under conditions which are brought about by a definite nutritional state. On the other hand, if there were no bacteriological evidence whatsoever of the nature of the affection, we could with practical certainty ascribe to it a bacteriological origin on the following basis of analogy: It shows a greater tendency to prevail at certain seasons than at others; it comes in epidemics, and most diseases with these qualities are of proven bacteriological source, and there is no reason to suspect the contrary here by virtue of any peculiarity in the behavior of the disease. It is a fever with acute onset and runs a definite course in common with other fevers of known etiology. Its conduct is in every practical sense parallel to that of another disease, gonorrheal fever, which is the constitutional expression of a disease that has ceased to be local, which attacks the joints in almost the same manner as does rheumatic fever, and affects the heart in practically the same way. In opposition to the theory that rheumatism may be caused not by a particular germ, but by any one of several pyogenic organisms, we note that the course of the disease, while greatly diversified, is too constant and classic in its evolution, too sensitively responsive to the therapeutic test to permit such an attitude, and this alone is enough to force upon us the suspicion of a specific germ.

I think, therefore, that in speaking of rheumatism we should never employ the term in the description of a symptom, but should limit its application to the conception of an acute, constitutional, self-limited infectious process, with a practically incontestable bacterial etiology, a proneness to find focal expression in the joints (arthritic type), or the endocardium (endocardial type), and to a less extent in other tissues, and a tendency to react specifically and characteristically to medication by the salicylates.

ARTHRITIS DEFORMANS AND ITS RELATION TO INTESTINAL PUTREFACTION.*

By EDWARD E. CORNWALL, M.D.,

BROOKLYN, NEW YORK,

VISITING PHYSICIAN TO THE WILLIAMSBURG HOSPITAL, TO THE NORWEGIAN HOSPITAL AND TO THE NEW YORK CONGREGATIONAL HOME.

Arthritis deformans is not the name of a disease, but of a clinical group. This group includes cases of deforming inflammation of the joints whose specific cause is unknown. As soon as we learn the cause of any case in this group we stop calling it arthritis deformans and class it with the disease to which it belongs by its etiology. The characteristic feature which is the bond of union in this clinical group is the association in joints of structural changes and deformity with inflammation. These changes involve destruction and proliferation of the joint tissues, but not, as in gout, deposition of sodium urate. The lesions may involve all the structures in and around the joint, the cartilages, synovial membranes, bones, capsular and lateral ligaments, nerves and muscles; but all these changes are not found in every case, and they commonly appear under three main types, which, however, merge into each other. In one type the lesions are found mostly in the synovial membranes and periarticular structures; in another, atrophic changes in the cartilages and bones are the dominating pathological features; and in the third we find hypertrophy and overgrowth of bone.

The clinical varieties of arthritis deformans generally recognized are the following: 1. Cases involving the finger joints chiefly or exclusively, with development of Heberden's nodes. These commonly begin in early middle life, though they may begin later. They are usually chronic from the start. 2. Cases showing progressive polyarthritis. These may begin acutely, and partial recovery or temporary improvement may take place, but more often the disease becomes chronic or is so from the beginning. Sometimes only a few joints are affected, but frequently the disease involves many joints. The progress of the disease is usually arrested after a time, but not often before considerable damage has been done. In extreme cases the patient may be completely bedridden and perhaps able to move only the joints of the hand, which are less apt to become locked than the other joints in this variety. 3. Cases involving only one joint. In this variety the disease usually affects the knee, the hip, the shoulder, or the spine. It occurs mostly in the aged. 4. Cases in which there is progressive ankylosis of the spine. The spine alone may be involved or in addition the characteristic lesions may appear in the hip or shoulder. The ribs may become fixed, compelling abdominal respiration. Pressure on nerve trunks may cause pain, paresthesias, and atrophy of muscles. 5. Cases differentiated as Still's disease. This disease is an acute arthritis occurring in children, in which the inflammation and enlargement of the joints are accompanied by fever, sometimes by chills, often by sweating, by anemia, and by notable swelling of the lymph glands and enlargement of the spleen.

Among the recent theories of the causation of arthritis deformans that of Poncet of Lyons deserves mention. He claims that "all joint conditions, but especially those hitherto called rheumatic, which cannot be associated with any specific cause, are really tuberculous." He does not mean that the joints are directly infected by the tubercular bacillus, but that they are irritated by an attenuated tuberculous virus circulating in the blood, which is derived from an already existing tuberculous focus in some other part of the body. The opinion most widely held at the present time regarding the etiology of the cases classed as arthritis deformans is that they are caused by specific infections or the absorbed products of specific infections or putrefactive processes. To the writer it seems more reasonable to believe that these arthritides are due to several rather than to a single specific cause.

Among the toxic agents which have been suspected of causing arthritis deformans are the poisons produced by the putrefaction of animal proteids in the intestines. I have had personal experience with one case which seems to have been largely due to this cause, and I will give a report of it; but before doing so I will ask your indulgence for a few words on the subject of the relation of the putrefaction of flesh proteids in the intestines to disease in general.

Numerous varieties of the bacteria of putrefaction are regular inhabitants of the human intestine. Flesh proteids ingested supply them a suitable culture medium; for not all the flesh proteids ingested are changed into soluble peptones and absorbed before these bacteria can get at them; it

*Read before the Medical Association of Greater New York, January 16, 1911.

has been estimated that at least ten per cent. of the flesh proteids which enter the alimentary canal fall a prey to the bacteria of putrefaction. Multiplying in this culture medium these bacteria make out of the complex albuminous molecule various substances, some of which can produce toxic effects on the organs and tissues of the body. Being soluble, these putrefaction poisons are to a considerable extent absorbed by the intestinal blood-vessels. The body in health is well protected against these putrefaction poisons, at least in the quantities normally present: first, by the intestinal mucosa, whose cells possess a considerable amount of toxicoyltic power; second, by the liver, which is our strongest defence against these poisons, and is able, judging from Bisso's experiments on dogs, to destroy two-thirds of the poisons produced by intestinal putrefaction; third, by the ductless glands which possess a toxicolytic function. The remnant of the putrefaction poisons which escape destruction by the intestinal mucosa, the liver and the ductless glands, are eliminated by the natural emunctories of the body, chief of which are the kidneys.

It is easy to see that the amount of the putrefaction poisons present in the blood at any time depends on a number of different factors. It is increased by meat diet, gastric and intestinal dyspepsia, dilatation of the stomach or intestines, constipation, disease of the intestinal walls, chronic appendicitis, and diseases of the nose and throat which contribute to the supply of putrefaction bacteria swallowed. Putrefaction toxemia is also increased by anything which diminishes the functional power of the physiological defenders of the body, notably of the liver. And it is also increased by any deficiency in the organs of elimination, notably of the kidneys. Several of these factors coexisting may produce great increase of putrefaction toxemia over the normal. A diet containing abundant flesh food combined with renal insufficiency can cause such an accumulation of these poisons in the blood as to excite uremic symptoms; and a liberal flesh diet with hepatic insufficiency or chronic constipation can maintain a degree of putrefaction toxemia sufcient to produce pathological results, especially in persons whose tissue resistance is low. The tissue resistance is a factor of great importance in estimating the effect of putrefaction toxemia. It varies greatly in different individuals. An amount of putrefaction toxemia which is harmless to one individual may produce serious disease in another. What is one man's meat is literally another man's poison.

There is little doubt that chronic putrefaction toxemia can produce, or strongly assist in producing, Bright's disease, arteriosclerosis, cirrhosis of the liver, obstinate headaches, epileptoid attacks, functional disorders of the heart and vasomotor system, irregular fevers, and neurasthenia. It can also aggravate the symptoms observed in the so-called lithemic condition. In all these conditions marked benefit is usually derived from treatment which diminishes putrefaction toxemia. It is from the beneficial results of such treatment that we sometimes are able to infer the etiological relation between this toxemia and particular conditions. Cases of arthritis deformans have been reported which improved very markedly under treatment directed against putrefaction toxemia; and this result followed such treatment in the case to which I have already alluded and of which I will now give a brief account.

The patient is a large framed, fairly well nourished woman of 75. Her mother and two sisters died of pulmonary tuberculosis, but she has never shown any signs of that disease. Since middle life she has suffered from arthritis deformans in the finger joints of both hands, all finally becoming affected. This condition was chronic from the start, but acute exacerbations with some pain and swelling of the joints occurred from time to time. The deformity steadily increased; some of the joints developed extensive spindle-shaped enlargement; in others the enlargement was more irregular; on several of the ultimate joints Heberden's nodes developed; motion was entirely lost in some of the joints. The patient also suffered from intestinal indigestion, had borborygmi, foamy and explosive stools, and frequent and severe headaches accompanied by flushing of the face. She suffered from neuralgic pains in different parts of her body from time to time. She gradually developed signs and symptoms of arteriosclerosis: the radial arteries became palpable, and she became uncertain in her walk, and had several falls, indicating cerebral arteriosclerosis. No marked signs of kidney disease were noted, though her blood pressure during the past few years has been high, about 180 mm.

The general treatment given in this case was protection from exposure, occasional saline purgation, moderate restriction of diet, and administration from time to time of tonics; Warburg's tincture in small doses was a favorite. For the acute exacerbations of the arthritis potassium iodide was given, almost always with benefit. The patient appreciated so highly the benefit she received from this drug that she always kept a bottle of it on hand so as to have it ready when an exacerbation occurred. For the intestinal indigestion she was given some of the medication commonly used in that condition, and her diet was restricted moderately. The headaches, which became her most distressing symptom, were treated by purgation, a modified migraine tablet and severe restriction of diet for a short time.

Such, in outline, was her treatment up to two and a half years ago, when I modified her diet by still further restricting her flesh foods; in fact, almost entirely cutting them out, allowing only at rare intervals a bit of chicken or steak; and by adding a daily ration of a quart of milk artificially soured by a culture of the lactic acid bacillus. This diet, which consisted of the soured milk, bread and butter, cereals, fruit and green vegetables, and very little else, gave her probably not more than fifty grams of proteid a day and 1500 calories. She has taken this diet steadily up to the present time, except for a rest of three months from the soured milk, which was called for by symptoms of overcolonization of the intestines with the lactic acid bacillus.

From the time she began to take the soured milk the symptoms of intestinal indigestion improved. The patient said "it went right to the spot." The flatulence disappeared and the stools became and remained normal. The headaches became much less frequent and severe and long periods elapsed without their occurrence. Along with this improvement in the intestinal symptoms, but unnoticed at first, was an extraordinary improvement in the condition of the joints. There was a cessation of the acute exacerbations; the progress of the disease was arrested; more than that, there took place a considerable amount of repair of the damage which had been done to the joints. The enlarged joints

diminished in size, so that the present enlargement is not more than half or two-thirds what it was, except in regard to the nodes of Heberden, which are unchanged, and the remaining masses to a considerable extent became soft and pulpy. Moreover, motion was restored to the joints in which it had been lost.

The history of this patient suggests that some cases of arthritis deformans are caused or aggravated by putrefaction toxemia, and also suggests the line of treatment that should be adopted.

Cases of arthritis deformans which are not caused or aggravated by putrefaction toxemia lack very definite therapeutic indications. Treatment in these cases is apt to be tedious, trying to both patient and physician. It is, however, not without hope, at least of arrest of the progress of the disease, which usually happens in time, though it may be a long time, and may be followed by a resumption of the morbid activity. We can hope for a stay in the progress of the disease in even the worst cases; and considerable improvement not infrequently takes place in very severe ones; cases almost completely bedridden, but with the joints necessary for locomotion not absolutely locked, sometimes surprise us by becoming able to get up, walk around, and attend to business. In this disease the least we can do—and often the most we can do—is to maintain the patient's bodily health and care for his comfort. Sometimes the aid of surgery can be invited with advantage. Of drugs administered for direct action on the morbid tissues, probably the best are the iodides, especially in the acute exacerbations. Tonics, particularly iron, are usually needed. The much overused salicylates, including the popular aspirin, can disturb the stomach and increase the anemia, but can do no good, except possibly as analgesics if used cautiously. I make mention here in this manner of the salicylates because I am led to believe that the majority of physicians prescribe them in the majority of cases of arthritis deformans in the acute or subacute stages.

The question of diet, especially in younger patients, when the putrefaction toxemia is not prominent, may call for a liberal answer; it may be necessary to "feed up" these patients; but it is the fats rather than the proteids that should be pushed; and these patients should not be compelled to eat more than their bodies can utilize. Nutrition should be improved as much as possible by hygienic measures. Local applications can be used sometimes with advantage; iodine and mild counter-irritant applications and dry heat are the best. "Roasting" the affected joints by means of the hot air box may give marked temporary relief, but I have found its use disappointing in some cases; the patients complained that the pain returned as bad or worse than before as soon as the joints were exposed to the air after the treatment. It is advisable after the "roasting" to protect the joints by wool or cotton batting. Massage for the benefit of the wasting muscles as well as for the general health of the patient is usually in order. For the extreme cases of polyarthritis, and also for less extreme cases of the disease, residence in a warm dry climate, such as that of Arizona or the pine belt of our Southern States, can be recommended.

In closing these few remarks I would like to emphasize:

1. The importance of finding out, in any particular case of arthritis deformans, if chronic putrefaction toxemia enters into the etiology.

2. The value of a diet of lactacid milk, cereals, fats, vegetables, and fruits in those cases which are caused or aggravated by chronic putrefaction toxemia.

3. The importance of "feeding up" in cases with debility and malnutrition, and the harmfulness of burdening feeble patients with an excess of food, especially putrefiable proteids.

4. The value of potassium iodide in some cases and the worthlessness of the salicylates in all cases.

5. The beneficial effects that can be derived from living in a warm, dry climate.

6. The necessity for patience and perseverance in treatment on the part of both invalid and physician.

1239 Pacific Street.

THE HOSPITAL AND THE YOUNG PHYSICIAN.*

By Wm. Edgar Darnall, A.M., M.D.,

Atlantic City, N. J.

There has never been a time when the beginning of the practice of medicine, a profession much overcrowded and much underpaid, offered more serious difficulties to the young man than the present. Since the rapid development of hospitals not alone in the large centers but also in most cities of smaller size there has been added to the usual difficulties of keen competition, high cost of living, youth, inexperience, lack of adequate acquaintance, and added to the other drawbacks the young practitioner has to face the serious competition of hospitals and dispensaries. It used to be that when the young physician began his professional career his practice was made up of the poorer classes, the slum patients, and those charity patients whom some well established practitioner turned over to his care because of not having time to give to them. While it might have been true that they did not remunerate him richly in money they gave him a start, paying him what they could, and praising him for his successful efforts so that he became known in the community while acquiring a better class of patients and establishing his foothold. As the situation now is, this class of patients goes straight to the local hospital or dispensary, receiving free treatment and daily encouragement in the pauperizing not only of themselves but the profession too. The young physician waits and waits for work while the hospital eats up his bread and butter.

In large cities where there are teaching institutions and much clinical material is needed for demonstration, or perchance to make a better showing than a rival hospital, no patient is ever turned away from the hospital or dispensary. In smaller cities some care is exercised, but there still remains much abuse of such charities by people well able to pay for medical treatment. Each time a hospital or dispensary so treats a patient able to pay for it, it is robbing some man of a fee, which, small though it may be, in the aggregate would go to make up his yearly income, and hand his name on to other patients. The hospital thus becomes the young man's greatest competitor, a real obstacle to a successful beginning of his career, and therefore providing a strong temptation to resort to things unprofessional, questionable, and even sometimes criminal.

How many a young physician owes his first in-

*Paper presented at the midwinter meeting of the American Academy of Medicine, held at Buffalo, N. Y., Dec. 5-7, 1910.

troduction to a community to being hastily summoned in some emergency or accident to a prominent citizen whose case he carried to a successful issue, thereby gaining for himself a standing among those who could help him to success? Who ever thinks now of calling in the young doctor nearby if an accident should happen? The policeman on the corner sends for the ambulance, the patient is rushed to the hospital, and it all goes into the daily routine of the institution. He is not even needed to administer an anesthetic for that is done in the hospital, and the hospital seems to take away all that which should come to him.

What becomes the moral effect of all this on the young man equipped and ready, full of the activities and enthusiasm of life, and with an itching desire for work? His expenses go on just the same. He is not allowed to advertise or bid for work. Is it any wonder that he becomes discouraged? Day by day his discouragement grows till some fair day the loquacious representative of some lodge appears with a glowing account of how he may widen his acquaintance, build up a fine practice, and soon be one of the leading men of the community, if he will but become their lodge doctor, and that they want some one who is active, young, and a hustler. Is it much wonder that he catches at the bait and accepts the offer? Perhaps it is well to preach and prate about upholding the dignity and honor of the profession by eschewing contract practice, and it is all right, but with the dignity and the honor of the profession at one door and the wolf hammering away at the other, which becomes the greater necessity? The dignity and honor may wait for the future but the landlord demanding the month's rent and the young man's necessity for bread and butter must be provided for. It is largely this class of men who are doing the contract practice and who in most cases are doing it not from choice but in order to make both ends meet. How many a discouraged beginner in the profession has been forced even further! Realizing that he must grasp the only straw in sight or sink financially, he betakes himself to the ways of the advertising quack or the criminal abortionist. Once having started the downward path and lost his professional caste it becomes impossible forever for him to retrace his steps.

To the young man even of good ability but without financial backing or influence the competition of hospitals may seem in the beginning the greatest barrier to success, yet if he is fortunate enough to get himself connected with some hospital in a capacity however humble at first, the hospital may be of the greatest service to him. Its advantages professionally so far outweigh the disadvantages financially that they are not to be compared. It is undoubtedly true that there are many good men who are forced out into private practice improperly equipped, because although endowed with the necessary ability to make good clinicians, the financial necessity of gaining an immediate income is such that they are deterred from taking dispensary positions, which would give them experience and skill, because they cannot spare the large amount of time required and for which they get no money remuneration. While they are devoting their best energies to the dispensary they are losing the calls from valuable patients outside. This they can ill afford to do. The clinics therefore often lose men who might prove valuable and able, but the men themselves lose an education and training in methods of work which is indispensable to the properly equipped physician.

How then does the hospital help the young man fresh from college and full of book science, who has no experience and whose outlook on a great profession is raw? First his internship brings him in intimate contact with the best of the profession enabling him to be started along right paths. The ability to apply practically what he has learned is developed within him, besides a systematic way of doing things. He learns that not all of medical lore is to be found in printed books or prosy lecture and he sees something of the personal relation between physician and patient, which sociologically is a most important thing. If afterward he acquire a position in some hospital it will stimulate him to put forth his best efforts in scientific attainment. If he has ability along any certain line it will give him the opportunity to demonstrate it. In discussing this question recently with an assistant of mine who was on the point of leaving me he remarked that: "Wherever he settled he intended to get into some hospital even if he had to start by scrubbing the floors."

The hospital becomes for the young man a finishing school in which the mind is trained to accurate methods and correct reasoning. The daily habit of thoroughness, diagnostic accuracy and the ability to go straight to the point, laying aside the nonessential and unimportant, after a time become habitual. The shiftlessness and lazy methods of much of the general practice of medicine are largely due to the fact that private practice has been entered without the education and training of a good hospital, and carelessness creeps in because there is no one to criticise. The hospital man, however, is under the fire of criticism always. His work is all charted and is an open book. He must submit to the criticism not only of men of older and richer experience, but also of the younger men with newer methods and even the interns themselves fresh from the laboratories and the schools. It behooves him, therefore, that his work should be of the highest grade and the pride of his reputation cannot afford that it be otherwise. His position demands that he should stand for all that is best and most scientific in medicine. If he has not the ability to carry these things out and maintain his front with his colleagues his reputation must suffer and his mistakes, like the lawyers', become "hung on trees."

This critical fire to which he is subjected, however, brings out whatever qualities he has and stimulates him to give the best that is within him. The daily exercise of the scientific habit of mind, reasoning correctly from the facts presented to accurate conclusions, and the necessary routine thoroughness of his work so educate the mind to proper methods of thought that after a time carefulness, thoroughness, and accuracy become habitual. Besides this the daily necessity in hospital work of frequent consultations in the many departments of medicine brightens the mind by a constant attrition with other scientific minds of ability, while the experience and training the hospital gives beget an education the character of which cannot be found anywhere else.

The bane of the medical profession is poor diagnosis; poor, because carelessly made. It is not that the busy practitioner has not the ability, nor is it, at the start, a difference in knowledge so much as it is a difference in the training of systematic and routine method of work and of thought. Those analytic habits of the hospital that make the con-

clusion certain are too much belittled or too much neglected. Physical examinations, laboratory examinations of blood, sputum, urine, feces, etc., are not entered into. Often the laboratory report is the one fact that throws the die deciding which of two conditions is present, and it may be very important to know which. The consequence of neglect to avail oneself of scientific methods results in a diagnosis that is often a guess. Likewise snapshot treatment must follow snapshot diagnosis, and often the patient whose life might have been saved is snapped away into eternity because the psychological moment of safety has been passed by ignorance of what was the matter until too late.

The greatest good the hospital does in any community is not so much what it does for the individual as the good it does in sending out men trained to the scientific habit of mind, and whose influence and authority as leaders are reflected in the general diffusion of sanitary knowledge in the community. The value of a hospital to a community is directly expressed by the individual value of the trained minds of its staff to the community. The influence of such trained minds must necessarily elevate the general professional average by setting a high standard, to which others must at least try to approximate. This is reflected indirectly by the members of the profession to the community itself, which thus becomes more enlightened as well as more exacting in what it demands of the profession. The leadership of such minds thus formulates the view society acquires of the great questions of sanitation and the conservation and protection of health. Therefore whether benefit is derived or efforts prove futile in all great public health crusades becomes largely a matter of the degree of the enlightenment of the public and that in turn must rest on the kind and quality of the knowledge disseminated and the caliber and training of the minds of the leaders of the profession to whom society looks for guidance and direction in all such matters.

The development of such leadership has largely been from the ranks of hospital workers. The social influence of the atmosphere of splendid humanitarianism exemplified by the groups of hospital workers and the daily intimate contact with scientific minds can but be felt and absorbed by the young man, and must increase his breadth of vision into the great philosophical and professional questions of the day. He becomes, therefore, trained and qualified to stand before the world as an exponent of those high ideals of action that make ours the most respected of all professions.

SOURCE OF ERROR IN THE DIAZO REACTION.

By SAMUEL LEVINSON, D.Sc., Ph.G.,
BROOKLYN, N. Y.

The diazo reaction suggested by Ehrlich is based on the formation of some coloring matter produced by the combination of some substance or substances in the urine, the nature of which are still unknown, with a diazotized aniline. Usually a diazotized sulfanilic acid is employed. The sulfanilic acid solution (1 part of sulfanilic acid in 100 parts of a 5 per cent. solution of hydrochloric acid) is mixed in the proportion of 1 to 40 with a solution of sodium nitrite (1 part of sodium nitrite in 200 parts of water). This mixture added to an equal volume of urine gives a red color after the addition of ammonia.

Among the substances which when present in the urine give a similar reaction is phenolphthalein. Of course in this case the reaction is simply due to the presence of alkali, ammonia, which turns the phenolphthalein red-pink. The pure pink color of a solution of phenolphthalein becomes redder in the case of urine which contains different pigments, so a mistake can easily be made. This reaction, of purely theoretical interest up to a few years ago, becomes of real importance at present, when phenolphthalein, its derivatives, and preparations containing this drug are so extensively used.

When a urine shows the diazo reaction it now becomes necessary, in order to avoid mistakes, to ascertain whether the reaction is not due to phenolphthalein. As the presence of this drug can be easily demonstrated by the addition of alkalies it is only necessary to test the urine with a few drops of some alkali; a pink or reddish color shows the presence of phenolphthalein. If this reaction is negative we have a true diazo. But in case this reaction is positive (the urine becomes red after the addition of alkalies), we may have phenolphthalein alone, or a true diazo, together with the reaction produced by phenolphthalein. In order to test the urine in such a case of a suspected "mixed" reaction we have to add a few drops of some acid to the test tube in which there is a positive diazo reaction. If the color disappears altogether and appears again only after the addition of enough alkali to render the mixture alkaline, the reaction is due to phenolphthalein alone. If after the addition of acid the color becomes lighter, but does not disappear completely and becomes more intense by addition of enough alkali to render the mixture alkaline, the reaction is due to the substance or substances producing the true diazo reaction and also to the presence of phenolphthalein.

As to the frequency of the appearance of the phenolphthalein reaction in the urine, it may be said that this drug does not always appear after being taken internally, as may be demonstrated by direct experiments. This reaction seems to appear occasionally in the urine; and every time we have proved the presence of this drug in the urine the fact was confirmed by questioning the patient, when it was always found that he has taken some preparations of phenolphthalein. With the above test it will be easy to distinguish between a true diazo reaction and the one given by phenolphthalein.

161 Tompkins Avenue.

A CASE OF BLOOD EXTRAVASATION INTO THE SCLERA FROM INDIRECT VIOLENCE.

By FREDERIC GRIFFITH, M.D.,
NEW YORK.

The clinical interest in the present report lies in the causation of the condition producing the ruptured vessels. Two days ago the patient, a young female, blonde, about 5 feet 3 inches tall and of 120 pounds weight, came, accompanied by a male companion, and giving the history. Margaret, an English gymnast, aged 23 years, engaged in circuit work with her consort in trapeze team performing. The final trick of the pair may be described as a swivel-spin; the man hanging head downwards supports the woman's body by means of a leather and metal ball-bearing swivel device, held in his teeth and hooked to her waist-belt. Commencing

to turn with the woman swinging limp her body suddenly becomes rigid and she revolves with a velocity of probably 200 revolutions a minute. This showy feat, the woman claims, did not make her dizzy nor did she ever close her eyes during its continuance after becoming adept. Three days before the visit, after coming off stage, she began to feel pain in the left eye and slight vertigo, but ascribing her condition to "cold" and "weak eyes," paid little heed. Her partner discovered upon inspection the presence of hemorrhage, staining the lower segment of the left eyeball and continuing into the eyelid. He began the prompt ministration of cold water and hot water applications, and had continued this treatment at frequent intervals night and day up to the time of their call. Continuing their engagements, two performances daily had been given, the woman, aside from slight local discomfort, experiencing no difficulty. Owing to the stationary continuance of the blood discoloration the two called for an opinion as to the advisability of their laying off. Examination shows a bright red blood cloud richly coloring the lower quarter surface area of the eye globe, extending beyond the conjunctival crevice to the eyelid and upwards to the episcleral margin. The skin surface below the lid was edematous, puffed, and stained as after a blow from a fist. The woman's muscles are soft and not prominent, her arteries soft, compressible, pulse normal. Treatment advised after application of weak cocain solution (1-10 per cent.) to the conjunctival sac and study of the case consisted of a simple boric acid wash, and continuation of cold in the form of iced eye-cloths, alternating with hot water fomentations, with calomel purgation. After considering the financial stress involved in throwing up of contract, I advised continuation of work, with elimination of the worst straining features in their performances, and for the future to close her eyes when undertaking the spin. One week later the patient was seen to be progressively better.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.*

By ROBERT H. M. DAWBARN, M.D.,

NEW YORK.

Fever on and After the Fourth Day.—After a major operation there is regularly some rise of temperature. This seems somewhat proportionate to the amount of muscular tissue cut or disturbed; for muscles have a second function—they are the furnaces in which the bodily heat is kept up by oxidation; and just as a poker stirs up a fire, so muscular irritation increases temperature. But after the third day the fever should, if asepsis has been successfully maintained, not be more than one degree above normal. If it is higher, and a few causes can be negatived—chiefly constipation, malaria and bronchitis—then it will be wise to examine the wound. Wherever redness is found at the edges, open it; where redness about a stitch, remove it. A suture through the skin—which always continues the home and abiding place of microbes, notwithstanding our best efforts—must have the soothing effect of a pole through a hornets' nest. That so rarely do these, our little tenants, resent it, would seem to indicate that they are better Christians than their landlord! As a measure of precaution, to reinforce your rigid asepsis by a single bit of antisepsis, let me strongly advise painting the whole raw surface of the wound with a single light coat of tincture of iodine, just before closure. If not a clean wound, and hence to be drained instead of closed, so much the more reason for doing this.

An Anecdote of a Famous Surgeon (to be taken to heart).—Be not proud of an extremely short incision. A longer one, in reason, will heal as quickly, to an hour. Daylight is safer than fumbling in the dark. That great surgeon, the late Dr. James R. Wood, used to say, with a twinkle in his eye, "We recognize a great operator, for one thing, by the length of his cuts. For each decade of my surgical life I have added an inch to the extent of my incisions, for the greater safety of my patients. Therefore, of late, as an old surgeon, I have given up such operations as circumcision, finger amputating, etc., because unable in them to make a cut long enough to be safe, according to the rule just named. Remember, too, that the bottom of any incision should be as long as its top. Do not make your wounds funnel-shape, that is. Searching for great vessels, or other important structures, at the apex of such a funnel is characteristic of the beginner." Of course, his remark as to the greater length each decade was intended to be taken with a smile, and with allowance. But the exaggeration was meant simply for added emphasis.

Needling of Bone—the Earliest Test of Malignancy.—For really hopeful results from surgery make your diagnosis of malignancy of bone early. Whether cancer, sarcoma, or tuberculosis, *softening*, due to decalcification, can easily be shown to be the earliest pathological change, clinically speaking; before any alteration of shape or size; even earlier than the *x*-ray can serve as a guide. Use an ordinary sewing needle; this cannot be made to enter even cancellous bone, if it be normal, without extreme force; and in malignancy the difference is plain—more as if entering cartilage. Lest it be snapped off and left in the bone, through some sudden movement of the patient, withdraw the temper from the point by passing it a moment through a flame, causing it to turn blue. Hold it firmly during this test by a needle holder. Compare the two sides, at exactly identical points, as to resistance to the entrance of the point. Differentiate from osteitis, from rachitis, from osteomalacia, etc. As to the first of these, the thermometer (when acute) plus, sometimes, a history of reason for there being inflammation; microbes in evidence, etc. The last two diseases involve numerous bones; they also present unmistakable constitutional symptoms.

The Photograph in Plastic Surgery, Especially of the Face.—When preparing to operate upon the face it is a wise precaution for self-protection never to proceed until a photograph has been taken and given to you. This must clearly show the deformity. The photographer must be instructed not to "touch it up" at all. Gratitude ever lessens with time. Indeed, its place may even become taken by resentment, as the ex-patient compares his own appearance with that of any and all friends who have never needed to have a countenance made over. However improved thereby, it is unjust to the surgeon to compare upon even terms his constructive work with that of Providence. That photograph may become needed as a reminder of the former appearance It may even prevent a lawsuit.

*See Medical Record, March 18, 1911.

What is a Felon?—There are five entirely distinct pathological entities, any and all of which regularly or often receive this diagnosis. They are identical only in three respects, *i.e.*: (1) All involve a region at or close to the end of some one of the digits. (2) All are of microbic nature, varying in severity partly according to the exact region involved, and partly according to the kind of causative microbe. (3) All are best treated by the early use of the knife, of course, under local anesthesia. These five kinds of felon are: (1) Septic cellulitis of the finger tip; generally from entrance of a dirty sliver, or similar agent. (2) Septic periostitis of the terminal phalanx. If that sliver, for example, penetrates a little deeper Nos. 1 and 2 will often result, being present together. No. 2 is the most agonizing of all, pus being pent under an inelastic, unyielding membrane. This, too, is the variety most often resulting in death of the last phalanx, in absence of prompt surgical intervention. (3) Septic arthritis of the last interphalangeal joint. This, it will be remembered, is quite close to the finger end. Indeed, it is practically in conjunction with the root of the nail. (4) Septic involvement of the root of the nail; the typical "runaround." (5) Septic thecitis of the sheath at the insertion of the flexor profundus tendon into the terminal phalanx. Since the time of Galen it has been known that this kind of felon is liable to spread rapidly up along the sheath involved, and running on into the wrist and forearm, in case the thumb or little finger be involved, but ending about where the finger joins the hand in the case of the three other digits. This is because of anatomical reasons given in every textbook.

Three Measures of Safeguard After Any Major Amputation.—Bearing in mind the risk of secondary hemorrhage for the first week, or a little longer, after any major amputation, there are three orders which you should never omit: (1) Have the stump elevated. If it be leg or thigh, in private practice turn a chair upside down on the bed; lay a thin pillow along its back, and bandage lightly to these. If the amputation be at any point through arm or forearm, elevate the stump upon a high pillow to which its dressings are fastened—by safety pins, for example. (2) Never permit the stump, during this period, to be covered with the bedclothes. It must always be visible to the attendant. Being at least as thickly covered by dressings as the other limbs are by bedclothes, it will not suffer from cold. (3) Prepare from a stout piece of bandage or sheeting a "Spanish windlass" of such size as to surround comfortably without compressing the stump at its junction with the body. This must not be removed; and if the patient inquires "what for?" tell him anything whatever except the truth. Why add to his misery a part of your load of anxiety and responsibility? Should that stump turn red the attendant's duty is *first* to twist a hair-brush in that Spanish windlass tightly, and *then* send for the surgeon. He very likely will have to "tie in continuity," but that is not what we are discussing. Were these three rules always adopted and enforced many a life would be spared that now is lost.

Spinal Analgesia (vs. Spinal Anesthesia)—Spinal analgesia has recently been described by Bier of Berlin, after between three hundred and four hundred personal instances of its use, as follows: "The safest form of anesthesia, especially in the weak and the old." And since if this is true, it is obviously so in the young and the strong—who is omitted? Generally I use two grains of tropacocaine. In nearly five hundred personal cases I have had no cause for regret. Even though one does not intend using it for operative purposes, yet he should become familiar with the technique for other reasons. For example: When fracture at the base of skull is suspected, if upon spinal tapping the fluid proves at all bloody the diagnosis is made. Again, in doubt of diagnosis, suspecting "spotted fever," the fluid will, if the *Diplococcus meningitidis* be the cause, prove milky in appearance, and the microscope will verify it. Once more, it is the ideal way in which to introduce antitetanic serum. Enter anywhere in the lumbar region, since in the adult there is no spinal cord below the dorsal vertebræ, unless we dignify by that name the terminal thread; and even that only covers the first lumbar. Do not introduce the questing needle in the usual direction, which may, following the terms used in studying a map, be called "the surgical attempt at the northwest passage." Instead, simpler and better in every way, use the direct or Peary route to the human pole; that in the median line. The tough ligaments will not stop the needle's advance if introduced properly. The writer is humbly of opinion that his spinal kit presents several advantages both of safety and convenience. The term analgesia is used instead of anesthesia as being more exact. One of the numerous early errors was the assumption, after the spinal injection of cocaine solution, that if the patient could still feel contact following a reasonable wait, he would necessarily also feel pain, and hence that the injection had proved to be a failure. Occasionally this is untrue; and then the operation can proceed painlessly, although there is retention of common sensation to a greater or less degree.

A Practical Point Alike in Fracture and Dislocation.—Never set one of the commonest of major fractures—Colles'—and never reduce the most frequent of important dislocations—those at the shoulder joint—without major anesthesia. First, for the sake of mercy; that should be reason enough. But again, many a patient, though brave, instinctively contracts for protection the muscles crossing the region involved, and thus sometimes renders almost impossible what otherwise would be easy work for the surgeon. Again, as to Colles', we have in breaking up the impaction to rock the fragments. Hence there will be laceration, more or less, of the tendon sheaths grooving the dorsum of the radius, against these sharp fragments. Obviously, more laceration rather than less, when those tendons are held rigidly tense, meanwhile; and a plastic teno-synovitis, binding them to their sheaths, and ending often in fingers almost immobile, is a thing worth avoiding, as is plain without discussion.

105 West Seventy-fourth Street.

Experimental Fat Embolism.—E. Fuchsig found that the intravenous or intraarterial injection of oil has an effect dependent upon the mass of oil and the rapidity with which it is injected. The oil can traverse many capillaries provided that the pressure with which it enters them is capable of overcoming the frictional resistance. Death follows the injection only of large quantities of oil (about 2 c.c. to each 1000 grams of body weight of the experimental animal in the case of injection into the jugular vein). Death may be of pulmonary, cerebral, or cardiac origin, but always as the result of embolic occlusion of the blood-vessels. The pulmonary form is the most common.—*Zeitschrift für experimentelle Pathologie und Therapie.*

DOES LIVING IN THE TROPICS SHORTEN THE LIFE OF EUROPEANS?

MR. JAMES CANTLIE, a well-known British authority on tropical diseases, has recently discussed the question as to whether residence in a warm climate shortens the life of Europeans (*Journal of Tropical Medicine and Hygiene*, Feb. 1, 1911). In the first instance he takes exception to the scope of the regions considered by British insurance companies as dangerous to the health of a white man and for living in which a higher premium is charged. He points out all the countries situated within 33° north of the equator and about 30° south, the region prescribed by the insurance companies, are by no means dangerously warm. For, example, there are large areas in Central Africa which cannot be surpassed anywhere in the world for salubrity of climate. In many other tropical zones there are large districts in which the climate is distinctly healthful. If heat in itself is to be regarded as the factor of danger, it is not then the tropical countries which must be looked upon as the most unhealthy, for the greatest heat is encountered in subtropical lands. In Cantlie's paper the countries of the Eastern Hemisphere to the north of the equator are dealt with.

At first, for a period of some months, a man born and bred in Great Britain, who takes up his residence in a warm climate appears to benefit thereby. The heat acts as a stimulant and the newcomer has a general feeling of well-being. In some six or eight months this initial stimulus wanes. The vigorous appetite flags, digestion becomes impaired, muscular energy ceases and exercise becomes somewhat of an ordeal. This is the critical period. If the organs of the body were sound to start with no permanent damage is likely to ensue; but if the digestive tract had been faulty ere he left home organic impairment will probably occur. Should, however, the individual starting with healthy organs not lead a life conducive to health in the tropics ill-health will overtake him. The first two years of residence in a tropical country is the crucial period for one born and brought up in the British Isles.

After a time if a man be wise he learns to adapt himself to the difference in climate and knows how to live the life best suited to the preservation of health. It is the newly arrived man, then, who runs the greatest danger. Age, too, has much to do with the retention and maintenance of health in the tropics. The younger the age at which a man proceeds to the tropical countries the greater the risk of contracting disease. According to Cantlie, one of the influences most injurious to the health of the white man in the tropics is the lack of proper rest and sleep at night. The chief dangers to life, excluding malaria, are the affections which attack the alimentary tract and abdominal organs. Any one by using proper precautions can defy malaria and yellow fever, as has been plainly shown by the experience of the Americans in Panama and neighborhood.

As for diet in the tropics, Cantlie remarks that for the most part good food cannot be had. Thus, this is doubtless a prominent factor in the "running down" process which always afflicts tropical residents. Alcohol is stigmatized as more of a curse in the tropics than in a temperate climate, and especially from the standpoint of health Cantlie's paper is illuminating and was written chiefly with the view of suggesting companies with regard to policies issued to residents in the tropics. The British insurance companies are chary of insuring persons who go to live in the tropics, and the consequence is that American companies step in. Caultie says the reason is that "British insurance offices have based their opinions as to the danger of modern life in the tropics on "gossip of fifty years ago and they affect to believe in dangerous and unhealthy areas of the globe on insufficient evidence." Most of the American life insurance companies have learned wisdom and no longer fine a man who ventures to take a trip in the tropics. Perhaps, most medical men who have had experience of tropical life are of the same opinion as the writer discussed above, that a healthy man can retain his health in the tropics provided he learns how to adapt himself to the conditions there. Modern medical science has done much and is still doing much to rid tropical life of its menace to the white man.

SOME RECENT VIEWS ON PELLAGRA.

PASSED Asst. Surg. C. H. Lavinder, U. S. Public Health and Marine-Hospital Service, in Public Health Reports, February 24, 1911, reviews at some length the experimental work of Raubitschek who seems to have been the first to take up, in an experimental way, the question as to the effects of exposure to sunlight upon maize-fed animals in association with the point of a possible relation to the etiology of pellagra. In the first place Raubitschek puts the theories of the etiology of pellagra into three groups, the bacterial, the toxic, and the autoxic, and concludes that not one of them, in its present state, can be considered satisfactory. His experimental work is too lengthy to be more than briefly discussed. The main conclusions resulting from his experiments are summarized by Lavinder as follows: He thinks he has demonstrated the presence of a photodynamic stuff in maize, and that this material is soluble in alcohol.

He brings out strongly the effect upon animals of changing the conditions of light without any modification of diet, and discusses briefly the symptoms displayed by the animals. He declares that he does not attempt to bring his experimental results into a strict relation with the etiology of pellagra, or to assume for this disease a photodynamic basis, or even to conclude that pellagra is produced by an almost exclusive diet of maize, good or bad, which displays its harmful effects first under the influence of light. The inference apparently is that his results are suggestive but not conclusive.

The work of two other investigators, Lode and Horbaczewski, is also referred to. Lode stated that in his experiments he had found that guinea-pigs, on a maize diet, exposed to sunlight, suffered after eight days from falling of the hair. This phenomenon increased up to the seventeenth day. Guinea-pigs kept in the dark, on the same diet, displayed no changes. All the animals lost weight. In his experiments he made use of a yellow variety of maize, and suggests an analogy to what is observed in fagopyrism. Animals fed upon white maize or alcohol-extracted maize, under sunlight, were negative up to the eighteenth day. They did not lose weight. Horbaczewski reports similar experimental work with very similar results. Lavinder, in commenting on the work of the three investigators, refers to the fact that the question of photodynamic substances has been much discussed of late, and states that "it may be briefly said in a general way that a great number of fluorescent bodies, both vegetable and animal, which are harmless in the dark have been shown to possess highly toxic properties in the light, especially direct sunlight. These properties include the power of exerting a deleterious influence on animal body cells and on certain protozoa." Fagopyrism, to which reference has been previously made, is a condition which arises in white or white-spotted animals fed on buckwheat or on other species of *polygonum* and exposed to the sunlight. The symptoms, according to Lavinder, consist of a severe erythema of the skin, or even a severe dermatitis, and there may be an associated disturbance of respiration, with general symptoms referable to the central nervous system, more particularly if the skin around the head be involved.

From the results of experiments and observations there seems to be little doubt that a relationship does exist between the pellagrous erythema and exposure to sunlight. However, the conclusions to be drawn from feeding experiments upon animals are indefinite and caution must be exercised before speaking dogmatically on the subject. Thus, as Lavinder states, "feeding experiments with maize, made by workers interested in pellagra, have produced many discordant results and very varied interpretations. To apply results of this kind to the explanation of a specific disease in man is difficult and uncertain." Efforts to solve the problem of the etiology of pellagra are being undertaken in almost all countries in which the disease exists, and accordingly the outlook for a successful solution is hopeful.

ANTIQUITY OF THE TELECARDIOGRAM.

A REMARKABLE subject, as well as a remarkable episode in that subject, seems to have escaped the watchfulness of the numerous and constantly increasing force of our professional brethren who love to explore the by-ways of medicine and to treat of certain subjects from the standpoint of non-technical literature. It remained for Friedel Pick of Prague to call attention to the fact that Einthoven's telecardiography was anticipated in the United States some half a century ago (*Münchener medizinische Wochenschrift*, February 21).

Eugene Groux, a German from Hamburg, was in many ways one of the most extraordinary characters who ever lived. Born with a fissure of the sternum, which gave opportunity for direct study of the action of the heart, he traveled throughout the civilized world, and was examined by over 2,000 medical men, each of whom inscribed his name in an album. He was examined by the most experienced clinicians and pathologists of the English-speaking countries. France, Germany, and other cultured lands, and the findings exerted great influence and considerable controversy in respect to our knowledge of cardiac activity. For much of his short life he was identified with the United States, especially with Boston and New York. He actually took a medical degree as a result of his constant identification with an important medical subject. He made a remarkable will, disposing of his body to the requirements of science. He filled positions as regimental and steamship surgeon and was a member of the New York Physicians' Mutual Aid Society. When he died in 1878 his autopsy was conducted by some of the best-known members of the medical profession of Brooklyn and elsewhere. His cleft sternum eventually found a resting place in the Army Medical Museum, Washington, D. C.

To come back to the subject of electric telecardiography, it is of interest to note that in 1859 Upham, in conjunction with Farmer, the electrician, and Prof. Pickering of Harvard, succeeded in connecting Groux's heart with a telegraph system in such a manner that tracings of the heart's action were obtained on a paper ribbon at a distance of four miles. Upham reported the experiments in the *Boston Medical and Surgical Journal* for that year. While Einthoven's results were obtained through a normal chest wall, this anticipation of his work is hardly the less interesting. Pick does not appear to realize that Groux was seen in person by the various European clinicians. However, it is true that as far as the telegraphic feature was concerned they had to depend wholly upon Upham's paper.

PRECOCIOUS SENILITY.

THIS condition has been described as occurring at almost all periods of life prior to actual senility—not only in middle life and early manhood, but also in adolescence, and even in childhood. Of recent years considerable interest has been aroused in respect of the existence of arteriosclerosis in the two last-mentioned periods. We may anticipate a little by stating that all diagnoses of arteriosclerosis *intra*

vitam in the child and adolescent must be regarded as open to some doubt. It has been shown quite conclusively that hard and palpable arteries in childhood are as a rule functional in character, due to an increased tonus of the arterial musculature.

For adolescents Krehl has shown that certain circulatory anomalies suggestive of arteriosclerosis are due to what he terms a growth hypertrophy of the heart, with or without dilatation. At a meeting of the Medico-Scientific Society of Jena last July (*Münchener medizinische Wochenschrift,* February 14) Faber sought to determine whether or not the growth hypertrophy of the heart was recovered from in mature years. He had access to the same individuals originally studied by Krehl. They comprised twenty-one men. These men had been under twenty-one when first examined and were now between twenty-seven and thirty and in apparent health. Broadly speaking it could be asserted that the heart affection had not undergone complete resolution, which perhaps would have been impossible. On the other hand, not only was the condition not progressive but in a large percent of cases improvement had resulted. In the great majority no dilatation could be detected, and in one-half the apex beat was much less forceful than in adolescence. Two only seem to have been rejected for military service, which gives a good idea of the benign character of the cardiopathy. In certain cases the so-called growth hypertrophy appeared to be equivalent to the athletic heart of the English and Americans. There appeared to be a permanent rigidity of the arteries, but whether it was due to the conditions which obtain in the elderly is left undecided in the absence of autopsies.

Milk from Slop-Fed Cows.

The subject of the feeding of cows intended for the production of milk on the waste of distilleries, breweries, beet-sugar factories, and oil factories has caused considerable controversy between the physicians who treat the disease of children and the owners of factories and distilleries who desire a market for the waste from their factories. It is no unusual sight in our streets to see wagons full of brewer's grains being carried along, and the observer wonders where they are being carried, and to what use they will be put. Inquiry shows that they are used to a large extent, a less extent than formerly, be it said, for the feeding of cattle. E. C. Aviragnet, in *Archives de Médecine des Enfants* for December, 1910, considers this species of food for animals at length. He bases his assertions on the clinical experience of himself and many other observers, as to the diseases caused in infants by the use of slop-fed milk. He unhesitatingly says that milk of cows fed on any kind of waste grains, beets, and oil residues is absolutely improper for feeding young children, although it may be used for older persons with less risks. The chief kinds of residues used in this way are beet-roots, distillery and brewery grains, and oil-cake from presses for the production of oil. Some of these substances are forbidden as food in many of our American cities. All of these materials are wet and subject to fermentation; some of them, especially distillery waste, are distinctly acid. The effect of these foods on the milk cannot be ascertained by ordinary chemical tests; these show no difference between such milk and that obtained from ordinary feeding on farm products. But the clinical evidence shows that they produce in young animals and in children intestinal troubles, diarrhea, fever, weakness, emaciation, and death if the feeding is persisted in. Among cows fed on these substances abortions are frequent. The substances that cause these symptoms are not detectable by ordinary chemical tests; they are toxins developed as a result of the fermentation of the food products eaten by the cows, which pass into the milk, and remain there even after the milk has been deprived of bacteria by sterilization or pasteurization. All such milk is entirely unfit for feeding infants. When we examine the sanitary code of the city of New York we find it stated that "milk drawn from cows fed on distillery waste, or any substance in a state of fermentation or putrefaction," will be designated as adulterated milk, and as such its sale is forbidden by law. Yet we are told on credible authority that in most of the dairies in which stall-fed animals are kept for the production of milk, in the city of Greater New York, more or less brewery waste is fed to the cows. It is self-evident that the use of pasteurization is not going to render such milk any the less toxic, and until we are able to prevent its sale altogether we may expect to have cases of intestinal catarrh in bottle-fed babies.

The Influence of Frequent Small Doses of Chloroform.

Some years ago Sir James Crichton Browne, in Great Britain, called attention to the habit in certain districts of consuming lozenges and jujubes containing chloroform, samples of the lozenges sometimes having as much as 2.9 per cent. of chloroform. He said that these lozenges were taken in considerable quantities, especially by children, both for their sweet taste and for the effects produced. He furthermore expressed the opinion that such repeated doses must have an injurious effect. In order to find out the influence of like doses of chloroform on animals a series of investigations have been undertaken at the physiological laboratory of Glasgow University, the results of which were published in the *Lancet,* January 21, by Dr. G. Herbert Clark. In the experiments rabbits were used and the amount of chloroform given was comparable with the quantity described by Browne as being present in one linseed, licorice, and chlorodyne lozenge. The summary of the investigations was as follows: 1. Chloroform repeatedly administered by the respiratory passages, subcutaneously, and by the stomach in small doses rapidly kills rabbits. 2. The liver shows degeneration of the cells sometimes so marked that the whole center of the lobule is broken down into débris. The cells in the center of the lobule are early affected, those further out later. Fat is always present, generally in large quantities. 3. The kidney suffers to some extent, but relatively more when the chloroform is inhaled than when it is injected or given by the stomach. Fat is occasionally found in degenerated cells. 4. The spleen shows intense congestion, the sinuses being packed with red blood corpuscles, and along with the red corpuscles an orange-colored pigment is generally present which reacts to the stain for iron. Very many large phagocytes are present in most cases. The average weight of the spleen was 0.46 gram heavier than in the controls when chloroform was inhaled and 0.59 gram and 0.17 gram heavier when injected and when

given by the stomach respectively. 5. Degenerative changes were observed in the cardiac muscle. Fat was not observed in any of the hearts examined. These experiments show that the effect on rabbits of small and repeated doses of chloroform is in a high degree injurious. Undoubtedly, also, the influence of similar doses on children or adults is harmful.

Snakes as Plague Preventers.

Professor Sambon of the London School of Tropical Medicine has been publishing a series of articles on plague in the London *Times* which contain some somewhat original and novel views and information. In the issue of February 4 he points out that the flea is paramount in plague epidemics as it is in plague epizootics. The most efficient prophylactic measures employed by the ancients against plague were those which affected more or less directly these insects. In a pamphlet on plague published in Rome in 1743 we read that in time of plague we should not suffer in our houses the slightest dirt, but keep them scrupulously clean on account of the grave danger that insects born of filth bring with them. Sambon also draws attention to the fact that fleas not only are a menace as regards the dissemination of plague, but they may also play an important part in the transmission of many of our more common diseases, not excluding tuberculosis in that form known by the name of scrofula. According to the same writer rat-eating snakes were introduced into Rome in 291, B.C., when Rome was devastated by the plague. Pliny states that "the Esculapian serpent was imported into Rome from Epidauros, it was kept in public institutions and also in private houses." It is also known that the Egyptians kept domestic snakes in their houses. From far back times throughout the East snakes were kept in houses for the purpose of destroying rats and of preventing rat-conveyed diseases. Sambon is of the opinion that nonvenomous rat-snakes are a far better protection against plague than cats and dogs, on account of the fact that they do not harbor fleas nor are they likely to convey the plague in their own persons as cats, at least, have been credited with doing. This information is interesting, but not of so much practical importance as the writer seems to think, since the supply of nonvenomous rat-eating snakes must be limited and these reptiles would probably not live in the climate of England.

Vaginal Menstruation.

Abnormal types of menstruation have received much study in all ages. By far the most commonly known are the different forms of vicarious menstruation which need not be discussed in this connection. Tubal and vaginal menstruation are not included under the vicarious type and the possibility of their existence has been much in doubt. Richter, at a recent medical session of a local society at Stettin (*Berliner klinische Wochenschrift*, February 13), described what he believes to be a unique case of vaginal menstruation. The patient, aged nineteen, had atresia of the hymen and had never menstruated. After this condition had been removed she began to menstruate quite regularly. She was found to have a hypoplastic uterus and ovaries, while the vagina was the seat of numerous small hemorrhagic cysts. The latter were removed with much trouble, but reappeared at the next menstrual period. Some of them burst spontaneously, but others remained closed and required removal. The formation of hemorrhagic cysts occurred with each menstruation. The author assumed that the phenomenon could only occur in a vagina lined with cylindrical epithelium corresponding to that of the cavum uteri, but had no opportunity of verifying his assumption.

Effects of Mineral Water Cures on Albuminuria and Cyclindruria.

Every physician who seeks to clear up albuminuria in patients who are seemingly in good health—such, for example, as those who have made application for life insurance and have been postponed indefinitely—knows how difficult it is to secure the desired result, whether he relies on diet, hygiene, or drugs. Dr. Zörkendörfer of Marienbad reported to the Society of German Physicians in Prague some remarkable results along this line (*Berliner klinische Wochenschrift*, January 30.) The public which takes the water cure at this place is made up largely of patients with metabolic disturbances (diabetes, gout, obesity) and subjects with vascular disease. It is not surprising that albuminuria, whether dependent or not on actual nephritis, is extremely common—no less than 62 per cent. have either albuminuria or cylindruria or both. In 15 per cent. simple albuminuria was present. Cases of false albuminuria are not included. Of the true albuminurics the urine cleared up in no less than 30 per cent. and 51.2 per cent. showed improvement. In 11.5 per cent. the condition remained unchanged and in 7.2 per cent. it became worse. The material consisted of nearly 500 cases.

News of the Week.

Tenement House Control.—The Congestion Committee appointed by the Mayor of New York has prepared several bills for introduction into the present Legislature designed to relieve the overcrowding of tenements and to prevent it in the future. These bills limit the height of tenement buildings, except on Manhattan Island, to four stories, provide for fireproof construction, and increase the number of cubic feet of air space for each occupant of a tenement house to 600 cubic feet for an adult and 300 cubic feet for a child. The commission also endorses bills requiring inspection of tenement houses and providing for the vacating of those unfit for habitation.

Hookworm and Deficiency.—Students at Wofford College, Spartanburg, S. C., who fail in their examination hereafter will be examined in order to determine whether or not they are suffering from hookworm infection, on the ground that the failure may be due to the disease as often as to mental inefficiency.

Fire in Hospital.—The inmates of the old dormitory building of the New Jersey State Hospital for the Insane at Morris Plains were thrown into a panic on the morning of March 21 when one of the woman patients set fire to the eight beds in the ward of which she was an occupant. Smoke filled the corridors and wards, but fortunately the fire was confined to the room in which it was started, and there were no serious results. The old building is the only one of the group lighted by gas, and although all the jets are high and protected, it occasionally happens that inmates have succeeded in igniting papers, sheets, etc., by tossing them into the lights. The State Legislature has been asked for an appropriation to permit of the installation of electric lights.

Quarantine Decision.—The controversy between the Board of Health and the Board of Education of Paterson, N. J., in regard to the school attendance of children from houses in which there are cases of contagious disease, has been settled by the decision that any child may attend school unless there is a case of contagious disease in his immediate family. Heretofore all children in a house in which such a case occurred have been debarred from attendance at the public schools, and the contention was made that this rule was unnecessarily stringent.

Christian Science Healer Indicted.—The New York County Medical Society has succeeded in obtaining the indictment by the Grand Jury of a Christian Science healer on the charge of practising medicine without a license in violation of the public health laws. When arraigned in court the healer pleaded not guilty. The case will be brought to trial, and will be used as a test to determine the legal standing of Christian Scientists who charge fees for their services as healers.

The Antivivisection Bill.—The bill introduced into the New York Senate by Senator Bayne and favorably reported by the Judiciary Committee provides for a commission to investigate the question of vivisection, the expenses of the commission to be borne by voluntary contributions. It is reported that the necessary amount has already been oversubscribed. The State Medical Society has sent to each member of the Senate a letter signed by Dr. J. D. Bryant, Dr. John S. Thacher, chairman and secretary, respectively, of the committee on experimental medicine, and Dr. Frank Van Fleet, chairman of the committee on legislation, protesting against the passage of the bill, which, in spite of the disclaimers of its sponsor, is essentially an antivivisection measure. The probable attitude of the two members of such a commission who would represent the humane societies is indicated by the following extract from the last annual report of the A. S. P. C. A.: "The worthlessness and inhumanity of the majority of the experiments to which animals are subjected are beginning to impress themselves more and more on the public mind, and must ultimately result in the restrictive legislation which humanity demands."

Railroad Accidents.—During the month of January the total number of accidents on the railroads in New York City was 4,799, an increase of 6.8 per cent. over the number for January, 1910. The number of passengers carried during the same period increased only 6 per cent. The number of fatalities was, however, much diminished, the total number of killed being 20 in January, 1911, as against 33 in January, 1910. These figures cover both the street and the steam railroads within the city limits.

Beth Israel Hospital.—The new children's ward of Beth Israel Hospital, New York, which has been built on the roof of the main wing of the hospital building, was opened on March 19. The ward has accommodations for twenty-five patients and comprises an open-air and an inclosed part, together with a special diet kitchen, an isolation ward with four beds, and outdoor and indoor playgrounds overlooking the East River. The cost of constructing the ward was about $10,000.

Census of India.—The returns of the provisional census just taken in India place the total population at 315,000,000, an increase of more than 20,000,000 since 1901.

Opium Congress.—The American Delegates to the International Opium Congress to be held at The Hague in July have been announced by the State Department. They are Bishop Charles H. Brent of the Philippines, chairman; Dr. Hamilton Wright of Maine, and Henry Finger of California. Bishop Brent served as presiding officer at the previous conference held in Shanghai in 1909, and Dr. Wright was also a delegate to that conference.

Gifts to Charities.—The Children's Hospital of Boston, Mass., receives a bequest of $25,000 under the will of the late Mrs. Worthington, who died recently in Pittsfield. The Clarkson Memorial Hospital of Omaha, Neb., and the Sunnyside Day Nursery of Wellesley, Mass., also receive $5,000 each.

Abolish Common Drinking Cups.—A new section of the New York City Sanitary Code which was adopted on March 21, to take effect on October 1, 1911, reads as follows: "The use of a common drinking cup or receptacle for drinking water in any public place or in any public institution, hotel, theater, factory, public hall, or public school, or in any railroad station or ferry house in the city of New York, or the furnishing of such common drinking cup or receptacle for use in any such place, is hereby prohibited." In commenting upon the ordinance, Commissioner Lederle stated that it was passed as the result of a bacteriological examination of various cups used in common, the necessity for drastic action being clearly indicated.

The Battersea Brown Dog.—By order of the Battersea Borough Council, London, the famous "brown dog" was broken into small pieces on March 23, and the inscription on the base of the memorial was excised. This is the statue which was erected by certain antivivisectionists in England to the memory of a stray animal which, it was alleged, had been subjected to painful experiments in a London hospital. It was proved in the courts that no such experiments had taken place, yet the antivivisectionists refused to retract their wilful misstatements. The presence of this concrete lie in a public square has always been the cause of much controversy, and the statue has from time to time been badly damaged by medical students who denied the truth of the inscription setting forth the alleged cruelties to which the animal had been subjected. Its final removal is an evidence that the authorities regarded it as an incitement to rioting.

Spinal Meningitis in New York.—Two fatal cases of spinal meningitis in New York, during one week, both victims being young physicians, have called general attention to the possibility of the spread of the disease in the city. In the first case, that of Dr. Ashley of Dr. Doty's staff, the infection was in all probability obtained at the autopsy on the body of one of the passengers on a Greek steamer, who died during the voyage. In the second case, that of Dr. Raymond, an interne at the Hudson Street Hospital, the source of the infection was not determined, no cases of the disease having been under treatment in the institution. In both cases the disease assumed a very virulent form and ran a brief course, which was apparently not influenced by the Flexner serum. Several other cases and some deaths have been reported on steamers arriving from Greece. Both Commissioner Lederle and Dr. Doty, however, have joined in assuring the public that there need be no fear of an epidemic of the disease, the greatest safeguard under present circumstances being the close cooperation which exists between the health officer at Quarantine and the Department of Health. The last serious epidemic of the disease in

New York developed in 1905, during which year 2,755 cases were reported. During 1906 there were 1,032 cases; during 1907, 828 cases; 1908, 308 cases; 1909, 346 cases, and 1910, 242 cases. The Department of Health, as previously announced, has taken over the preparation of the Flexner serum, and is prepared to furnish it and to supervise its administration whenever requested.

Free Eyeglasses for Public School Pupils.—A bill was introduced into the New York State Legislature on March 24, requiring the Board of Education of the city of New York to furnish free eyeglasses or spectacles to pupils in the public schools upon certificates from the principals of the schools that such glasses are needed. The Board of Estimate is required by the bill to appropriate at least $15,000 for this purpose.

American Medical Editors' Association.—The forty-second annual meeting of the American Medical Editors' Association will be held at the Alexandria Hotel, Los Angeles, Cal., June 26 and 27, under the presidency of Dr. J. MacDonald, Jr. Unusual efforts are being made for this annual convention, and members are urgently solicited to be present. The executive committee assures those who will attend a most interesting session from both a literary and a social viewpoint.

Midwives in New York.—During 1910, out of a total number of 129,031 births reported in New York, 52,010 were attended by midwives and 77,071 by physicians. These figures show the necessity for a careful supervision of the midwives, who are licensed by the Board of Health under the State law passed in 1907. Since the middle of February a plan has been in operation which makes this inspection more satisfactory than has heretofore been possible. The city has been divided into 140 districts, each in charge of a medical inspector, corresponding to the school inspection districts. Each inspector is required to visit the midwives in his district at least once a month, and to report any irregularity in work or equipment or any unsanitary conditions in their homes. Special investigations are also made in all cases in which complaints against midwives reach the department.

Removal.—Dr. L. Bolton Bangs, Dr. James Pedersen, and Dr. Frederick W. Smith announce the removal of their offices to 40 East Forty-first Street, New York.

Dr. William H. Welch of Johns Hopkins University, Baltimore, has received from the German Emperor the decoration of the Royal Order of the Crown, Second Class.

The Peoria (Illinois) Medical and Dental Societies held a combined meeting followed by a dinner at the National Hotel on March 15, at which Dr. Alfred C. Cotton, president of the Illinois State Medical Society, was the guest of honor.

San Joaquin Valley (California) Medical Society.—At the annual meeting of the society held on March 14 at Fresno the following officers were elected: *President,* Dr. W. E. Lilley of Tulare; *Vice-Presidents,* Dr. G. H. Aiken of Fresno, and Dr. C. O. Mitchell; *Secretary,* Dr. G. T. Hopkins; *Treasurer,* Dr. T. M. Hayden.

Complimentary Dinner.—The Bergen County (New Jersey) Medical Society on March 14 gave a complimentary dinner to Dr. J. J. Haring of Tenafly and Dr. S. J. Zabriskie of Westwood, the oldest and next oldest members of the society.

International Commission on Control of Bovine Tuberculosis.—A meeting of this commission was held in Buffalo on February 27, at which it was decided that the first work undertaken should be the preparation of a small pamphlet or primer for public distribution on the subject of bovine tuberculosis. The preparation of this primer was entrusted to Dr. V. A. Moore of Cornell University; Dr. J. R. Mohler of the Bureau of Animal Industry; Mr. J. J. Ferguson representing the American packers, and Dr. M. H. Reynolds and Dr. F. Torrance representing the American and the Canadian veterinarians, respectively. The next meeting of the commission will be held in Toronto late in August.

Congress on Thalassotherapy.—The fifth international congress will be held in Kolberg, Germany, from June 5 to 8, 1911, under the patronage of the Grand Duke of Mecklenburg-Schwerin. The program is now being prepared.

American Gastroenterological Association.—The fourteenth annual meeting of the American Gastroenterological Association will be held at the Bellevue-Stratford, Philadelphia, April 19 and 20, 1911.

Harvey Society.—As previously announced, Dr. S. Weir Mitchell of Philadelphia will deliver the last lecture of the season before the Harvey Society on Saturday evening, April 1, at 8:30, at the New York Academy of Medicine. The subject of the lecture will be "William Harvey, the Discoverer of the Circulation of the Blood." Ladies are especially welcome.

Milk Depots.—The Committee on the Reduction of Infant Mortality of the New York Milk Committee is planning to open on May 1 sixty depots for the distribution of pure milk for babies. Fifteen stations will shortly be opened by the Department of Health in Manhattan, Bronx, and Brooklyn boroughs. These will be administered by the board, but the milk will be sold and handled entirely by private concerns under agreement with the department. These stations are established for two specific purposes: First, they will serve as educational centers, where physicians and nurses will teach mothers how to feed and take care of babies; second, the stations will be the means of providing at as low a cost as possible pure and wholesome milk for infants.

Story County (Ia.) Medical Society.—The following officers were elected at the annual meeting held at Ames on March 4: *President,* Dr. F. H. Connor, Nevada; *Vice-President,* Dr. B. G. Dyer, Ames; *Secretary-Treasurer,* Dr. H. D. Chamberlain, Nevada; *Delegate to State Convention,* Dr. A. B. Maxwell, Ames.

Seventh District (Ga.) Medical Society.—At the semi-annual meeting in Cartersville on March 9 the following officers were elected: *President,* Dr. W. J. Shaw, Rome; *Vice-President,* Dr. A. B. Greene, Cartersville; *Secretary-Treasurer,* Dr. Tanner Lowry, Euharlee.

Wayne County (Ohio) Medical Society.—At the annual meeting held on January 10 at Wooster the following officers were elected: *President,* Dr. Charles A. Lerch of Wooster; *Vice-President,* Dr. Thomas A. Elder of Wooster; *Secretary,* Dr. Thomas A. Graven of Wooster; *Treasurer,* Dr. Henry B. Blankenhorn of Orville.

The Late Drs. Elizabeth and Emily Blackwell.—At the recent annual meeting of the Women's Medical Society of the State of New York, the following preamble and resolutions were adopted:

Whereas: Since the last annual meeting of the

Women's Medical Society of New York State, Dr. Elizabeth Blackwell of Hastings, England, and Dr. Emily Blackwell of New York City have been removed by death. *Whereas:* This Society recognizes that the Doctors Blackwell were not only pioneers in the study and practice of medicine in the nineteenth century, but by their wise, unselfish, and persevering efforts opened the way for other women to enter the field of medicine. *Whereas:* The members of this Society realize not only that a great loss has been sustained in the death of the Doctors Blackwell but that a responsibility has fallen upon all women physicians to maintain the high standard which they set in medical education, in hygiene, and in advancing the best interests of women in the home. *Resolved:* That we as a Society hereby express our deep respect for and appreciation of the character and work of the Doctors Blackwell, our indebtedness to them, and our earnest desire to carry forward the work they so nobly began. *Resolved:* That this action be spread upon the minutes of the Society, a copy be presented to the immediate family of Dr. Elizabeth Blackwell and Dr. Emily Blackwell, and sent to the leading medical journals.

The Late Dr. Edward G. Janeway.—At a meeting of the Society of the Alumni of the Presbyterian Hospital, the following minute was adopted: "It is with great sorrow and regret that the Society of the Alumni of the Presbyterian Hospital has learned of the death of Dr. Edward G. Janeway, for many years consulting physician to the hospital. Doctor Janeway typified in his life and works those qualities of mind and character which make for all that is best in the life of a good physician. His skill as a physician was universally recognized as of the highest order and his advice and friendly services were always most helpful, not only to the sick, but to those of the profession and especially to its younger members and to his students, who sought his aid and counsel in professional matters. In the death of Dr. Janeway, the medical profession and the community at large have suffered the loss of a warm friend, a wise counsellor and able humanitarian. The Society wishes to express its personal grief in the death of Dr. Janeway and to extend the sympathy of every one of its members to his family, and has instructed its committee to send a copy of this resolution to Mrs. Janeway and to enter it upon the minutes of the Society."—Arthur M. Jacobus, David Bovaird, Herbert S. Carter, Committee.

Obituary Notes.—Dr. James William Dodd Hancock of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1898, associate surgeon in the Ear, Nose, and Throat Department of the Williamsburg Hospital, and a member of the New York State and Kings County Medical Societies, the Brooklyn Medical Society, and the Brooklyn Medical Association, died in St. Mary's Hospital, Jamaica, of injuries received a few days previously in an automobile accident, on March 22, aged 40 years.

Dr. Nathan Foster of Center, Mo., a graduate of the Drake University College of Medicine, Des Moines, Ia., in 1863, died at his home on March 10, aged 84 years.

Dr. William Clark Cooper of Troy, N. Y., a graduate of the Albany Medical College in 1881, died at his home on March 17, aged 51 years.

Dr. Peter J. Roebuck of Lititz, Pa., a graduate of the Medical Department of the University of Pennsylvania in 1860, a member of the Pennsylvania State and Lancaster County Medical Societies, and the American Medical Association, and for two terms a member of the State Senate, died at his home on March 9, aged 73 years.

Dr. Henry F. Klenke of New Haven, Conn., a graduate of the Medical Department of New York University in 1892, died at his home on March 22, aged 43 years.

Dr. George A. Walters of Wesley, Ia., died of pneumonia on March 14, at the age of 39 years. He was a graduate of the Rush Medical College, Chicago, in the class of 1895.

Dr. Raymond W. Brown, house physician at the Hudson Street Hospital, New York, a graduate of the Medical Department of the University of Pennsylvania in 1909, and formerly an interne at the Nursery and Child's Hospital, died after a brief illness from spinal meningitis, on March 23, aged 25 years.

Dr. William T. Masterson of Birmingham, Ala., a graduate of the Louisville Medical College, Kentucky, in 1890, died on March 17, following an attack of paralysis, aged 55 years.

Dr. Benjamin Dudley Williams of Oxford, Ala., a graduate of the Medical Department of the University of Louisville, Ky., in 1884, a member of the Alabama State and Calhoun County Medical Societies, and former president of the latter, died at his home on March 12, aged 57 years.

Dr. William W. Jungels of Dubuque, Ia., a graduate of the Rush Medical College, Chicago, in 1900, died at his home after a brief illness, on March 13, aged 33 years.

Correspondence.

MUNICIPAL PROVISION FOR THE CONSUMPTIVE POOR.

To the Editor of the Medical Record:

Sir:—In your report (in the issue of March 11) of my remarks made at the annual meeting of the County Medical Society in regard to the inadequate provision for the consumptive poor of this municipality, the reporter failed to catch either the words or the spirit of my remarks. I did not object to enthusiasm in such a worthy cause, for, with Dr. Van Dyke, I believe "it is a poor wagon that starts out with creaking and groaning," and, as a matter of fact, I have in the past paid dearly for enthusiasm expended in this very direction. What I did object to was misdirected enthusiasm, or enthusiasm wasted by insufficient knowledge of the facts. I asked a few questions which I thought ought to be answered clearly and definitely before more moneys were appropriated for this purpose:

1. Did the members know that about $1,000,000 had been appropriated for the Sea-View Hospital on Staten Island five years ago?

2. Did the members know that this institution was planned for 800 cases of pulmonary tuberculosis?

3. Did they know that six buildings were under roof one and one-quarter years ago?

4. Could anybody give information regarding the long delay in the opening of this institution and whether friction between two great departments of the municipality played any rôle in the delay?

May I add, Mr. Editor, that these queries were not answered at the meeting, nor have they been answered since that time. But the Tuberculosis

Committee of the Charity Organization Society has appointed a committee of five, of which I have the honor to be chairman, which hopes to throw some light upon these matters, as well as upon a recent official communication that two more years must elapse before the doors of the Sea-View Hospital are thrown open.

ALFRED MEYER, M.D.

NEW YORK, March 25, 1911.

THE RELIEF OF PAIN IN ACUTE OTITIS MEDIA.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—The following treatment has given excellent results in the relief of pain arising from congestion of the middle ear occurring in the course of acute otitis media. A solution of magnesium sulphate, three drams, in one ounce each of distilled water and glycerin is warmed and poured into the external auditory canal and retained there for ten or fifteen minutes. The relief in most cases is immediate, and in not a few cases the inflammatory symptoms disappear without further treatment. Its action is due, in a large measure at least, to the exosmotic properties of the solution. The general practitioner may find this method of treatment serviceable.

J. D. THOMSON.

ATLANTA, GA.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE OBSTETRICAL DISCUSSION.—HUNTERIAN LECTURE ON THE IMMUNITY REACTION.—RONALD ROSS ON HIS ENUMERATIVE METHOD.—SMALLPOX OUTBREAK.—MEASLES.—OBITUARY.

LONDON, March 10, 1911.

A FULL dress debate, extending over two days, has been held in the obstetric section as to the indications for treatment of women with contracted pelvis who have been long in labor and are exposed to septic infection. The discussion was opened by Dr. A. Routh, who drew a sharp distinction between clean and suspect cases—the mortality differing from 2.9 H. C. in the former to 17.3 in the latter, and when cases had been previously subjected to much examination and attempts at delivery by other means the mortality rose to 34.3 (22 deaths in 64 cases). He pointed out that various operations had been adopted to prevent the maternal mortality of the classical cesarean section, and the fetal mortality of craniotomy, and said all forms of pelviotomy and all varieties of extraperitoneal section were unsuitable in cases that were definitely septic. He discussed the views put forward at the International Congress and some of the effects of the bacteria that might be present. He hoped films from swabs taken from the amniotic cavity, the cervix, or upper vagina would be found by a brief examination, to be afterward confirmed, to give useful information. Cases at present must be treated on the basis of the most virulent germs present. He described various types of cases as to rupture of membranes, previous treatment, fever, bacteria, etc., and the measures suited to each. In suspect cases, the membranes being ruptured, if the amniotic fluid and cervical contents were sterile cesarean section would be safe, but if pathogenic organisms were present a radical operation would be desirable. The brief examination of films by a competent bacteriologist would perhaps decide this important point. Where this was impossible, as often in general practice, craniotomy would perhaps still be sometimes required as the ultimate resort.

Dr. Hastings Tweedy hoped the discussion of this valuable paper would relegate craniotomy on the living child to the obsolete barbarities of the past. It was melancholy that some skilled operators at home as well as abroad still recognized it. He was tired of statistics of cesarean section; the deaths under it would as likely have occurred under craniotomy, for they were not due to the operation but to the complications of labor. Where bacteria could not be demonstrated hysterectomy was better. In the most favorable conditions with the os fully open pubiotomy was better still and easier to perform than craniotomy, and asepsis could be assured. Patients walked in seventeen days and suffered no inconvenience at any time.

Dr. Briggs doubted if bacteriology could at present give decisive indications. Many infections were local only, and suspect cases offered room for many errors. Many cases which might have undergone cesarean section successfully had, he knew, done well with induction of premature labor.

Dr. Edge would enlarge the scope of cesarean section as apart from sepsis as the safest and least mutilating plan in contracted pelvis. In doubtful cases he would do it, first using Dr. Maxwell's irrigation.

Dr. Arnold Lea said cases were often brought to St. Mary's Hospital after being subjected to examinations by midwives and doctors, the latter having tried forceps. Such were held "suspect" cases. In sixteen cases of that type, operated on after rupture of membranes, fifteen recovered. In the last seven years none of that type had died. A tube introduced into the cervix would give a specimen of the fluid, and in hospital practice a report could be obtained in half an hour. Streptococci were presumptive of pathogenicity. In obvious infection the only safe treatment was by complete abdominal hysterectomy.

Dr. Herbert Spencer said if a case were suspect because the membranes were ruptured every woman was infective, for they always had them ruptured, and generally had been examined. Bacteriology might help in the future. At present he could not trust it. In gravely infected cases section should not be done. Where forceps had failed the child's life was often compromised and craniotomy should be done, and if the uterus were torn he would supplement it with vaginal hysterectomy.

Dr. Lewers said early statistics and later differed much. He remembered when surgical instruments were not boiled. He would not wash out the uterus before operating. It would not be easy to do it thoroughly with the fetus in it. There was more chance of carrying something in than washing out all septic material.

Dr. Ernest Shaw suggested that injection of polyvalent antistreptococcic serum would do good in the most common infections. After operation some might be put into the uterus and peritoneum, applied to the wound, or used hypodermically.

Dr. Gow distinguished infection of the patient from that of the amniotic fluid. In Dr. Routh's "suspect" cases it was the fluid, not the patient, that was suspect. It was peritonitis which killed the patients, and that was set up by infective liquor amnii being admitted into the peritoneal cavity.

Dr. Maxwell opened the second day's debate and

described the case which led him to adopt the plan of irrigation with normal saline solution followed by incision of the eventrated uterus. The object was to get rid of infected liquor amnii, or, at any rate, dilute it. A douche tube was easily passed up to the fundus, beyond the fetal head, and the saline fluid, at 105° Fahr., allowed to flow for five minutes. The uterus was then eventrated and incised at the fundus, after carefully packing off the peritoneal cavity. After closing the uterus gloves and towels were changed, and the abdomen sewn up with fresh instruments. Of course, the plan would not be proper if the head were impacted.

Mrs. Scharlieb approved the plan, but when repeated examinations had been made, or forceps tried, there was not only infected cavity, but often injury to cervix and cesarean section could not avail. Craniotomy was a sad necessity, but in some cases gave the woman a chance. In India she had saved many lives by inducing premature labor, and had never found any ill consequence.

Sir F. Champneys would only refer to one point, the "alleged inevitable abrasion of the cervix" in craniotomy. Now this operation was only perforation of the fetal head, and did not inflict such injury. If extraction were meant, that was a separate thing, and not always necessary. Many cases might be left to nature after perforation. Even this was unpleasant to do, but less repugnant than leaving the mother to die undelivered.

Dr. Wallace described a plan he had tried of sewing the parietal peritoneum to the walls of the uterus by two rows of overlapping sutures all round an opening six by three inches into the uterus, extracting the child, and leaving a drainage tube. Foul, purulent discharge came through, and sloughing occurred, but the patient recovered.

Dr. Griffith said it was their duty to investigate these cases, for the general practitioner had to trust his experience rather than bacteriology.

Dr. A. W. Russell said it was not the suspect cases that always went wrong. He laid great stress on disinfection of the operator, and all others—masks, armlets, gloves, etc. He never eventrated before incising the uterus, but packed it round with swabs. When the child was removed he peeled off the placenta and membranes, and thoroughly cleansed the interior of the uterus, even scraping with the scalpel where it seemed softened.

Dr. Leatham said films gave useful information when pyogenetic cocci were numerous. He was not hopeful that differential staining would for some time to come help to determine between pathogenic and nonpathogenic organisms.

Dr. C. H. Roberts said at Queen Charlotte's Hospital they got desperate cases at times, every possible attempt at delivery having been tried outside. The child was dead, or dying, craniotomy and perhaps embryotomy was necessitated, and yet the women often had a normal puerperium. He thought cesarean section in such cases would be an additional risk for the mother and could not save the child.

Dr. Eden said most speakers regarded the liquor amnii as the danger—its infection was only one factor; the chief risk was infection of the uterus, and it was mostly an ascending one. If it had certainly occurred removal of uterus was needed, and he preferred the supravaginal operation with free drainage, both suprapubic and vaginal.

Dr. Sam Cameron said it was often impossible to say if the case were infected or not, and the virulence of organisms varied so they did not influence his procedure. He was guided by the condition of the patient. If the child were alive and the woman not moribund he performed cesarean section—never craniotomy.

Dr. Macnaughton Jones (President) conveyed to Dr. Routh the high appreciation of the section for his valuable, exhaustive communication, and said a few words on the points discussed, and quoted a number of foreign authorities. These some readers will have seen in your other reports, so that with the full account I have given of the discussion here they may be passed by. Dr. Routh replied by some remarks, and thanked the section for their appreciation.

"The Immunity Reaction in Diagnosis" was the subject of Dr. d'Este Emery's Hunterian lectures at the Royal College of Surgeons. The specific changes that occur on infection are extremely complex and differ greatly in different diseases, and the lecturer instanced the processes in the tissues and blood which are a reaction against the tubercle bacillus as altogether different from those reactive to the typhoid bacillus. The cure of an infective disease involved two opposed factors: an increase in the defensive forces, so that the body tends to become immune, and a raising of the sensitiveness of the body to the infection, so that it tends to become less immune. The latter process seemed to be an essential precursor, or accompaniment, of the former. It was called anaphylaxis, *i.e.* the opposite of prophylaxis, and best seen in tuberculosis, the final effect of a tuberculous lesion being to increase the susceptibility of every part of the body to the tuberculous toxin. Indeed, this toxin—tuberculin—did not affect the normal body, except when sensitized by a previous dose. The tuberculous fever (if not secondary) apparently was an anaphylactic reaction to doses of tuberculin too small to act on a healthy person; but this stage seemed essential to the production of immunity. Both anaphylaxis and immunity were specific, so that anyone immune to tuberculin was no less susceptible to other toxins.

Either reaction might therefore serve for diagnosis, a clear demonstration of either being a definite proof of infection, present or past. But how far can one or the other be employed in practice? This question the lecturer treated with full knowledge, and explained the conditions with great skill, but withal so far, I think, the general practitioner will feel that the processes required are such that in the stress of his daily work they will be scarcely practical, though in the bacteriological laboratory they may seem to be certain and will perhaps be further simplified. Thus the lecturer remarked that the two stages—hypersensitiveness and immunity—might coexist, *e.g.* one who had had large doses might not react because his blood contained much antituberculin, though his tissues might still be anaphylactic and the disease spreading. This difficulty was very great in regard to tubercle bacilli; perhaps because most people have acquired some degree of immunity, as had been proved by necropsies. Almost every one was being constantly vaccinated against tubercle bacilli through the alimentary and respiratory canals. Strictly there was no local disease. However small the lesion, changes follow in the blood and all the tissues. The tissues elaborate the blood, and it was the tissues that had to be defended. Their study was therefore of highest importance, though more difficult than that of the blood, and was consequently less advanced.

It was the presence of antibodies in the blood that had helped investigation. By antibody was meant a substance in the blood serum resulting from the presence of a foreign proteid which was called its antigen. As an example, egg albumin injected gives the blood a property of precipitating a similar solution of albumin. That property would be due to a new substance, or antibody, and was called precipitin. Antigens were always proteids, and always specific—so diphtheria toxin leads to the antigen called diphtheria antitoxin, which has no action on tetanus toxin. Of course, a pure proteid is not seen in the toxins with which we have to do, being very complex bodies, to which fact might, perhaps, be due some anomalies met with in disease. An antigen and its antibody, when mixed, will unite, and the properties of the latter be altered, and in such alteration the classification of antibodies has been arranged.

Diagnosis of infective diseases by demonstration of a specific antibody was simple in theory, but not in practice. Few were so easy as that of typhoid. The lecturer then outlined the main antibodies to the tubercle bacillus and its toxin, and estimated their value in diagnosis. From his elaborate statement I gathered that the processes require a degree of skill and an amount of time which the practitioner must at present leave to the bacteriologist.

Professor Ronald Ross, at the Tropical Society, gave some further account of the enumerative method in malaria and other diseases. The systematic counting of organisms should take the place of merely detecting parasites. Without such enumeration they could but seldom reach real proof of many most important propositions. They might almost say the history of medicine was one of defeats due largely to the absence of, or impossibility of, numerical exactness. Dr. David Thomson had made about six hundred daily counts. It was found that the numbers of asexual forms diminished gradually after the febrile period until about the middle of the apyrexial interval, and then increased again until numerous enough to cause relapse. There was no sudden or absolute disappearance, as previously supposed. Quinine was not immediately lethal to all the parasites, but they could not plot the curve of reduction, nor could they say whether the drug became more and more or less and less marked day after day. But that was just what they wanted to know to find how long it would require to continue the drug to obtain total extirpation.

In sleeping sickness a periodic cycle was shown. Daily counts of trypanosomes in a case contracted three months previously revealed a phenomenon not observed before—that the parasite curve rose and fell regularly about once a week. This discovery helped them to test the effect of treatment. The case was unfortunate, as there was great effect on the patient's eyes of atoxyl, though they were obliged to give it. On April 5 they injected four grains at the commencement of a parasitic rise, but it did not apparently check it; nor could they say the following doses caused reduction. But possibly without the drug the parasites might have increased in number. At the end of the case the curve was the same as at the beginning. Quinine, methylene blue, trypan red, mercury succinamide, izal oil, potassium iodide, trypsin, and amylopsin had no marked success, although the two first named seemed to benefit the edema to some extent.

The smallpox outbreak has shown no sign of being checked. The time of incubation has expired since it began, and some cases have occurred since. There have been altogether eight deaths, one of a nurse at the infirmary where the early cases occurred. Forty-five cases remained under treatment in the Asylum Board's Hospital last night.

Twenty-four cases of measles have been admitted to the hospital from the several districts, bringing the total number up to six hundred arnd sixty-seven. Sir J. Gorst has given an address to a "church socialist league" on the community's duty to children, in which he touched on this disease and others, as well as notification, and amid some sensible observations managed, as so many nonmedical speakers do, to mingle a good deal of nonsense.

The London Hospital has lost a zealous worker in Dr. Ernest Wilson, who has died at forty years of age. He was appointed electrician and photographer in 1899, and was an expert in both departments. *X*-rays were just coming into use at that time, and with radiography fell to his charge. With all care—for he knew quite well the risks—he was attacked by *x*-ray dermatitis, and had to lose fingers, an arm, and axillary glands successively. Later lung disease set in and he died on the 1st inst.

Major George Bent, late of the R. A. M. C., died on March 3 at the age of fifty. He took the two London College diplomas in 1885, and joined the army in the following year. He served in the Hazara expedition, 1888, and was awarded the medal and clasp. He retired in 1906.

Mr. J. A. Tapson has died at the age of eighty-three. He was the oldest practitioner at Clapham, where he resided sixty years. He took the M. R. C. S. in 1848, and joined the College of Physicians in 1886.

Dr. Wm. Williams of Cardiff has died after a brief illness. He obtained a science scholarship at Oxford, and several prizes at St. Mary's Hospital; having in due course taken the college qualifications (1887) he proceeded to M.A. and M.D. at Oxford. He also took D.P.H., and became president of the South Wales Sanitary Association, and held various appointments of the kind. He had examined in Preventive Medicine for Oxford University, and for State Medicine at the London University. At the Royal College of Physicians he gave the Milroy lectures, 1904.

The Lumbosacral Articulation. An Explanation of Many Cases of "Lumbago," "Sciatica" and Paraplegia. J. E. Goldthwait.
Diverticulitis of the Sigmoid. W. P. Graves.
Report of a Series of Cases of Syphilis Treated by Ehrlich's Arsenobenzol at the Walter Reed General Hospital, District of Columbia. H. W. Jones.
Liquid Air in Surgery. I. C. Beebe.

The Lumbosacral Articulation.—J. E. Goldthwait presents the facts that the lumbosacral articulation varies very greatly in its stability, depending upon peculiarities in the formation of the articular processes and of the transverse processes; that these peculiarities not only result in less than the normal strength of the joint, but may represent mechanical elements which not only produce strain and cause pain but may lead to such great instability that actual displacement of the bones may result, with at the same time the separation of the posterior portion of the intervertebral disk. In such displacement, if the fifth lumbar slides forward upon the sacrum, spondylolisthesis, the condition is usually compensated for, and pressure upon the cauda equina or the nerve roots does not occur. If the displacement be upon one

site, the spine must be rotated and the articular process of the fifth is drawn into the spinal canal with such narrowing that paraplegia may result, or the crowding backward of the intervertebral disk alone may be so great as to cause similar paraplegia, but of more gradual development. Weakness of the joints or the partial displacements may cause irritation of the nerves inside or outside of the canal and produce the bilateral leg pains often called sciatica.

Diverticulitis of the Sigmoid.—W. P. Graves states that the clinical significance of the acquired diverticula of the intestine has only recently been recognized. The acquired diverticula of the intestine are nearly always multiple and may occur throughout the length of the intestine, though most commonly in the sigmoid flexure. The diverticula of the large intestine are of more important clinical significance than those of the small intestine. The etiology of the formation of diverticula in the intestine is referable probably to an inherent local muscular deficiency. The most common predisposing factor in causation is the accumulation of fat on the intestine, as is shown by the fact that the majority of diverticula of the large intestine occur at the attachment of the appendices epiploicæ. The pathology and symptomatology of diverticulitis simulate left-sided appendicitis. Some cases are cured spontaneously without operation. The operative treatment of diverticulitis consists in general of drainage in the presence of abscess or gangrene formation. In favorable cases resection of the bowel and anastomosis are indicated.

Salvarsan.—H. W. Jones notes that two relapses out of six cases occurred after intravenous injections, while no relapse occurred after an intramuscular injection; this is of interest as indicating a choice of methods in favor of the intramuscular. On the whole, from a standpoint of relief from suffering, leaving aside the question of permanent cure, arsenobenzol has been successful, as would be expected from the reports of other observers during the past half year. Finally, the shortening of the time of infectivity of the lesions of syphilis where arsenobenzol is used is of enormous importance in the military service from a sanitary standpoint and would alone justify its use, even if a permanent cure were not effected.

Liquid Air in Surgery.—I. C. Beebe contributes an article on this subject.

Gastric and Duodenal Ulcer.—J. B. Deaver states that chronic recurring indigestion due to ulcer or its complications, such as adhesions or cicatricial deformity of the stomach, which is characterized solely by disturbance sufficient to cause disability and malnutrition, should be treated by operation whether hemorrhage be demonstrable or not. At times these patients fear to eat because of the consequences, or, having eaten, the pain or discomfort leads them habitually to empty their stomachs by vomiting or the stomach tube. It is not wise to permit matters to come to such a pass. Besides exposing the patient to all the danger of complication he is rendered a poorer subject for operation. A large part, indeed almost all of, the mortality of surgery comes from delay on the part of the patient or his physician and should be charged up where it belongs.

Surgery of the Stomach.—C. D. Aaron discusses from the viewpoint of the internist the various stomach disorders that require surgical intervention.

Mercury in Tuberculosis.—B. L. Wright reports a case of acute miliary tuberculosis of pulmonary type in which apparent cure followed the use of deep muscular injections of mercury.

Rhinoscleroma.—J. Wright and L. W. Strong have demonstrated in scleromatous tissue the presence of neutral fat, cholesterin, and lecithin, but not in amounts exceptional at least in hyperplastic tissue. They have also found that the method of complement fixation, so far as it goes, shows the identity of *Bacillus rhinoscleromatos* or the bacillus of Frisch and that of Friedländer, contrary to the opinion of Goldzieher and Neuber.

Gallstones and Cancer of the Bile Tract.—J. A. McGlinn, as the result of an analysis of 9,000 post-mortem records in the Philadelphia General Hospital, notes that gallstones were present in eight of the eleven cases of primary cancer of the gallbladder. In primary cancer of the bileducts stones were present in three of the five cases. In the entire series gallstones were found in 507 cases. Studying these few cases it would seem that gallstones play an important part in the etiology of cancer of the gallbladder and bileducts, but in cancer of the liver and pancreas they are only incidental. They occurred no more frequently in cancer of these two latter organs than in cancer of more remote organs. There was a record of but one case of cancer of the duodenum; stones were not present.

Irrigation in Septic Abortion.—H. Weil notes in reviewing a number of cases of septic abortion that the treatment of continuous uterine irrigation was only resorted to when it was evident that the curettage was destined to fail to control the progress of the infection, and when, according to Vineberg, these patients almost invariably die. This excessive mortality is conclusive proof of the futility of medication in its various forms, intravenous and subcutaneous injections of salt or other solutions, nuclein, silver inunctions, and other procedures, and while the irrgation treatment is not in any sense advocated as a sure cure, it is the writer's belief that if this treatment is instituted as soon as one has reason to believe that the currettage is destined to fail, it will prove of distinct value, more so than any other known procedure, without in any way interfering with or inhibiting its use.

Individual Immunity.—W. Lintz states that in the light of present knowledge both phagocytes and antibodies share in the mechanism of immunity.

Pneumothorax with Acute Abdominal Symptoms.—E. J. G. Beardsley reports a case in which the onset of an acute pneumothorax caused violent abdominal symptoms that suggested a tentative diagnosis of rupture of a tuberculous ulcer. The patient died two days after the onset of the acute symptoms, and at autopsy there was found an extensive left-sided pneumothorax.

Pinworms and Caraway Seed in Infantile Appendix.—I. Kornblüh reports a case of this condition.

Journal of the American Medical Association.

Pain and Dysesthesias.—C. L. Dana refers to a certain kind of pains characteristic of simple neurasthenia, which largely signify a persistent autotoxemia. This is apt to be associated with the second class that he describes, the basis of which is often developed on a neurasthenia. There are also characteristic pains of psychasthenia and the obsessions. These perhaps involve especially the epicritic nerves. The mental attitude and reactions of the patient have to be considered and the pains of the traumatic psychoses largely belong in this class. The pains of the anxious and involutional depressions are specially numerous, bizarre, and characteristic. They form for each patient a sensory complex and seem particularly to involve the protopathic nerves. These psychic pains which he describes are not purely imaginary because there is a thoroughgoing parallelism between mind and body and there can be no morbid mental change without a corresponding neural one. These are what he calls attention or habit pains and are comprised in the second group of his classification. There is no simple test by which one can distinguish such pains from real organic ones. They are attended with some psychic defect, as distinguished from those associated with simple neurasthenia. A careful study of the mental condition of the individual patient is necessary for their proper understanding and treatment.

Migration of Sarcoma Cells.—R. A. Lambert and F. M. Hanes describe certain ameboid movements observed in the cells of rat and mouse sarcomas when cultivated *in vitro*. These movements are easily observed under the higher powers of the microscope. Pseudopods are thrown out on all sides and increase or decrease in size in characteristic amehoid fashion. The movements are not, however, as rapid as in amebas, which may be due to the rather firm consistency of the coagulated plasma in which they live. Fat granules appear very early, and it is interesting to watch them stream into a newly formed pseudopod. They remind one of the movements of erythrocytes and other inclusions in the cytoplasm of *Entameba histolytica*. If the specimen is removed from the warm chamber and examined microscopically at room temperature the majority of cells retract their pseudopods and become spherical. The authors suggest that this ameboid migration *in vitro* may explain the spread of malignant growths in the body tissues, as has been urged by Carl Lewin on theoretical grounds. The conception is specially helpful as an explanation of the spread and localization of cancer in serous cavities.

Duodenojejunostomy.—P. S. P. St. L. Moncure reports a case in which this operation was performed for the relief of postoperative regurgitant vomiting following gastroenterostomy.

Mammary Tumors.—W. L. Rodman states that no one, however skilled or experienced, can safely determine the nature of a lesion before operation in more than 75 per cent. of his cases. In the remaining 25 per cent. at least either diagnostic incision or the use of frozen sections will be necessary. He has confidence in the value of frozen sections in the diagnosis. Out of fifty cases he has seen but two mistakes. He quotes Charles Mayo as to the impossibility of anyone always being able to tell the character of a solid or cystic growth by naked-eye appearances.

Studies on Lipoids.—W. Koch discusses the lipoids under the following headings: Cholesterols, cerebrosids, phosphatids, and sulphatids.

Salvarsan.—C. H. McKenna states that this drug should not be used to the exclusion of mercury or the iodides.

Hematosalpinx.—J. R. B. Branch reports a case of this condition associated with cervical atresia.

Arrested Development of Abdominal Wall.—A. G. Wilcox reports a case of this condition associated with a shortened umbilical cord.

Bottle-Maker's Cataract.—R. von der Heydt notes that this condition is rarely observed except among those workers, such as glass-blowers, who are exposed at once to intense heat and light. This case was typical. There was an irregular disk of opacity in the posterior cortical zone of the lens, with a well-defined thickened border, with slight hazy opacities outside of and near the center of the disk. Greer describes it as a saucer-shaped opacity like a cobweb in appearance and situated immediately within the posterior capsule of the lens. Bakers have been known to have the disorder and cases have been reported.

Paradoxic Reflex.—A. Gordon states that this reflex may be elicited if the fingers press deeply on the middle or the lower portion of the calf muscles. The pressure must be transmitted to the flexor muscles of the deep layer; sometimes pressure must be combined with lateral movements of the superficial muscles. If the reflex is present, extension of the great toe, or of all the toes, will be noticed. This is a valuable sign for diagnostic purposes at the beginning of an organic affection, showing that the motor tract is being irritated; while Babinski's sign is of inestimable value in cases of a well-established lesion of the motor tract, the paradoxic reflex is a sign of a slight irritation or lesion of the same tract.

Autolysis of Crystalline Lens.—C. A. Clapp gives details of experiments which seem to prove that there is an autolysis of the broken-up fibers of the lens, but he cannot answer some of the questions it suggests. Whether this is increased by the action of some specific enzyme in the aqueous humor or not is difficult to say.

Virulence of Diphtheria Bacilli.—B. L. Arms and E. M. Wade draw the following conclusions: Clinical diphtheria is caused by virulent diphtheria bacilli. As a rule, following clinical diphtheria, the organisms retain their virulence as long as they persist. As a rule, virulent and avirulent bacilli are not found in the same case, but, as these cases do occur, several strains should be tested before they are reported nonvirulent. In diphtheria outbreaks a large percentage of the "carriers" harbor virulent organisms, although such carriers may develop no symptoms whatever. Cultures should be taken from all contacts before terminating quarantine in all cases of diphtheria.

Vacuum Pump in Sinus Disease.—J. A. Pratt recommends the use of the vacuum pump in sinus disease and as a routine diagnostic measure in cases of vague symptoms which may be due to this cause, such as headaches. It is the first principle of good surgery to drain if pus is present, and this is accomplished by the vacuum pump. By its use solutions are not left in a sinus nor are cavities infected, as is apt to occur in the washing-out process. The technique is very simple and is described as follows: The patient's nasal cavity is thoroughly cleaned, and then sprayed with a 2 per cent. cocaine solution to contract the tissues and render the sinus openings more patulous. After the pump is attached to the water faucet the patient is instructed to close one nostril and insert the nasal tip in the other; by swallowing, the soft palate is then raised and closes off the nasopharyngeal space, while the suction of the pump holds the velum tightly in place.

As soon as the patient feels the suction he should open his mouth, allowing the tongue to lie perfectly relaxed and breathing through the mouth. In the author's experimental work along this line he finds that ten minutes of actual suction is sufficient to empty the sinuses and give their membranes a stimulating hyperemia. When the discharge is very profuse he gives the treatment twice a day and, if necessary, gives the instrument to the patient for home treatment. There are great possibilities in these cases in which there is hypersecretion of the middle ear and its accessory cavities.

Primitive Obstetrics.—L. Weinstock reports a case which emphasizes the point that in a normal case the less the attending physician does the better it will be for the mother.

Method of Staining Tube-Casts.—H. B. Erdman describes the technique of his method.

The Question of Compulsory State Insurance of Employer's Liability Under the Workmen's Compensation Act, 1906. A. Benthall.

Disease of the Mouth and Rheumatoid Arthritis.—K. W. Goadby states that his study of arthritis deformans coincident with alveolar osteitis does not seek to establish a specific organism as the etiological factor in all cases of rheumatoid arthritis, infective fibrositis, muscular rheumatism, etc., but that in diseases of the jaws, especially rarefying alveolar osteitis, a streptobacillus is present, pure cultivations of which inoculated into or around the knee-joints of rabbits have produced symptoms similar to and indistinguishable from arthritis deformans; that in such disease of the mouth and jaws the treatment of the disease locally and by means of autogenous vaccine prepared from the streptobacillus has been associated with amelioration and disappearance of the arthritic symptoms in a greater number of instances than can be ascribed to fortuitous coincidence.

Operations for Vesical Calculus.—W. F. Haslam continues his historical review of this subject.

Resting Conditions of the Skeleton.—W. A. Lane states that in the child whose nutrition has been impaired by intestinal stasis and consequent autointoxication the amount of nutrition sufficient to produce normal bone is in abeyance. Consequently the bone is of subnormal density, while the periosteum and growing lines are abnormally active. The growing lines react much more markedly to pressure than do those of the normal subject. When this condition of the osseous system becomes a conspicuous feature it is called rickets. In a child affected with this condition thoracic respiration is held in abeyance and respiration is carried on rather rapidly and superficially by the diaphragm and abdominal muscles. The child assumes habitually the normal asymmetrical attitude of rest of the body such as exists when standing at ease. Typical scoliosis arises. Knock-knee results from the habitual assumption of the attitude of rest of the knee-joint. Flat-foot is due to the habitual assumption of the attitude of rest of the foot.

Education of the Deaf.—M. Yearsley continues his article on this subject.

Infectivity of Typhoid Fever.—A. Harris states that the persistence of infection bears no relation to the clinical signs. Carrier cases do not have such a marked influence on the spread of the disease as is thought possible.

Sporotrichosis.—E. von Oppenheim reports a case of this condition. The lesions were chiefly localized in bone.

Treatment of Rodent Ulcer.—A. Churchward has found that calciophosphate of uranium possesses great radioactivity and may be used in the treatment of rodent ulcer in the place of radium bromide. The ulcer is covered with a piece of lint, and over this is placed the mineral and allowed to remain for three hours each day. The advantages of this treatment are its simplicity and freedom from expense. Three cases are reported in which the treatment was successful.

An Unusual Case of Intestinal Obstruction.—E. A. Wright reports a case of this condition resulting from the presence of a mass of tightly matted hair in the small intestine.

Infantile Scorbutus.—F. Brachi reports a case of this disease.

British Medical Journal.

Some of the Common Injuries of the Knee Joint and Their Consequencies. W. A. Lane.
Injuries of the Lower End of the Humerus. C. H. Fagge.
Rheumatoid Arthritis. J. C. Briscoe.
Note on Two Cases of Pernicious Anemia Treated by Salvarsan. B. Bramwell.
Operations for Stone in the Male Bladder. W. F. Haslam.

Injuries of the Knee Joint.—W. A. Lane states that the most common injury of the knee joint is some damage to the internal semilunar cartilage. The symptoms of damage to the internal fibrocartilage vary considerably. In the milder form of injury there may be merely pain and tenderness along the anterior two-thirds of its length which exist only when the knee is bent; but the pain may be absent when the knee is retained in a position of extension. In the more severe forms the fibrocartilage is very swollen and tender on pressure, and may form a distinct protrusion along its length. Apart from this condition the best treatment for a damaged fibrocartilage is efficient massage and exercises commenced as soon as possible after the injury has been sustained. As long as the fibrocartilage is painful and swollen the patient should retain the limb in a position of extension when he gets about, which must at first be very little. If the damage to the cartilage is repeated, the sooner it is removed the better. Some years ago the author called attention to the fact that the large majority of cases of tuberculous infection of the knee joint originate in the local depreciation of vitality consequent on damage to the internal fibrocartilage. Believing that tuberculosis rarely affects patients whose resisting power is not depreciated by intestinal autointoxication he employs pure liquid paraffin as a vehicle to facilitate intestinal drainage, having completely discarded all drugs of a purgative character, and he has been most pleased with the result. Should the condition of the joint be such that it is not likely to improve under this treatment, he divides the ileum and puts it directly into the rectum as low down as he can.

Injuries of Lower End of Humerus.—C. H. Fagge states that the study of injuries of the lower end of the humerus is naturally divisible into two classes; one which comprises injuries occurring in childhood before the lower epiphysis of the humerus is united to the diaphysis; and the other, including fractures in adults, of the lower end of the diaphysis—the common type of supracondylic fracture. This distinction is in reality largely an artificial one, for a simple separation in children of the lower humeral epiphysis uncomplicated by any fracture is very

rarely met with; in fact, the common injury to the lower end of the humerus in childhood is in many features similar to that of adult life.

Rheumatoid Arthritis.—J. C. Briscoe states that the urine in patients suffering from rheumatoid arthritis contains too low a quantity of phosphate and is proportionately high in acidity. By the administration of phosphoric acid or of different forms of phosphates, as indicated by the estimation, bringing the proportion of these substances —acidity and phosphates in the urine—up to a normal, there is undoubtedly improvement in the general and local condition. The author therefore advocates the employment of the various forms of phosphoric acid and phosphates in conditions of chronic arthritis, as relieving pain and producing improvement in the local conditions of the joints and in the general physical condition.

Salvarsan in Pernicious Anemia.—B. Bramwell notes that in two cases of this disease treated by means of salvarsan administered subcutaneously in four doses marked and continued improvement resulted, both as regards the condition of the blood and the general symptoms.

Operations for Vesical Calculi.—W. F. Haslam continues his article on this subject.

Berliner klinische Wochenschrift.

March 6, 1911.

Action of Poisons and Drugs.—Prof. Traube generalizes somewhat on this comprehensive subject as a result of new developments in physics. The blood is a colloid medium, and amenable to laws which govern colloid media. The ultramicroscope has shown us literally that certain salts can alter colloid solutions. Both the nature and the concentration of the salts play a definite rôle. The changes induced are of the nature of coagulation or precipitation. The greater this flocculation in the blood the more the toxic or destructive action of a poison becomes enfeebled. The formation of antitoxins is conditioned directly by this power of flocculation. These results are due to the use of the ultramicroscope in the main, yet they can be checked up by other methods—for example, that of stalagmometry, as developed by the author, Ascoli, and others. This method is based on pure physics, and rests wholly on the cohesive forces of a drop of fluid however measured. Certain laws regulate the size of a drop and the number of drops. Toxic additions can work alterations here, just as antitoxic substances can antagonize them. The laws underlying such phenomena may be demonstrated in very simple colloid solutions, and hold good as well as if blood itself were used. If the test substance chance to be a coloring matter the changes are so much more sensitive in character. The author takes a two-tenths per cent. watery solution of night-blue, which is both basic and highly colloidal. This is standardized by the use of the stalagmometer, which gives information as to the number and size of the drops. This colloid solution is then treated with substance known to be toxic to the blood. The cohesion is notably affected, as measured by the drop standard. Color changes occur, but the author insists that no chemical alterations are present. Antitoxic phenomena are connected with substances which antagonize the molecular changes which cause the primary alterations in drop cohesion. Thus the antagonism of lecithin to cobra poison is purely physical in nature. The author admits that stalagmometry fails utterly in many kinds of colloid solution—that is to say, the action of medicinal or toxic substances cannot be wholly explained on physical grounds. But the subject of chemotherapy differs so much from that of physical therapy that no comparisons can be instituted.

Iodine Basedow.—The literature of this subject is constantly accumulating of late years, although Rilliet, as far back as 1859, gave a description of a syndrome due to iodine which in no wise resembled ordinary iodism. Quite recently the Kochers found that while iodides were often of benefit to the goitrous they could also set up a hypothyroidism. Only recently Theodore Kocher has coined the word "Jodbasedow," reporting cases where the giving of iodides for ordinary colloid goiter has set up the Basedow syndrome. But the latter may be set up in the nongoitrous, and part of the syndrome may be a swelling of the thyroid, although this is not necessarily present. Prof. Goldflam is the latest writer on the subject. He has seen an instructive case, and in consideration of the very extensive employment of iodides in diseases which are naturally sensitive to iodine (such as arteriosclerosis) he believes that the method of exhibition is all important. He would use the drug by inunction, and relies for this purpose on a much-vaunted patented combination of iodine with fat. If given by the mouth the drug should be exhibited in small doses. The enormous quantities administered to syphilitics are not indicated in other conditions. We must not forget that iodine is an agency for harm as well as good, so that the old therapeutic axiom, "primum non nocere" is fully applicable to the giving of iodine derivatives. The entire subject is of such interest that a monograph must soon be forthcoming.

Repeated Extrauterine Pregnancy.—According to Frank, statistics, even the most exhaustive and carefully compiled, show that repetition of extrauterine gestation in the same woman is very rare. The difficulty of making a satisfactory diagnosis in early pregnancy is, of course, apparent. Only operative cases should be included, and but 140 all told will pass muster, a very small number when we bear in mind the great frequency of ectopic gestation. The author is able to add two clean cut cases from Prof. Körte's clinic and one personal observation. The kind of pregnancy and the interval are the most interesting features, also whether the operation was done for rupture. In Körte's first case the first pregnancy is simply mentional as extrauterine, with rupture, for which laparotomy was done. The right adnexa were removed. Interval four years. Second pregnancy interstitial, ruptured. Laparotomy. In the second case laparotomy for rupture of left tube, which was extirpated. One year later rupture of a right interstitial pregnancy. Second laparotomy. In the author's case the interval was but four months. Two laparotomies, the first for rupture of the left, the second for rupture of the right, tube. All the interventions were successful. There was no history of abortion, or gonorrhea, or salpingitis. That bilateral extirpation of the adnexa was not done was due to the comparative youth of the women. Had they been elderly, and multiparæ, it would have been inadvisable to leave the other appendage in the abdomen.

Deutsche medizinische Wochenschrift.

March 9, 1911.

Multiple Sclerosis.—Prof. Schultze completes his serial article on the diagnosis and treatment of this affection. We must differentiate carefully from several diseases, notably progressive paresis, and in any condition with apoplectiform seizures; from paralysis agitans (by reason of the tremor), and especially from hysteria. Diagnosis by excluding these conditions should not seem difficult, but in any severe affection of the cerebrospinal axis something more is required. There are traumatic psychoneuroses which vary much among themselves, so that an exact diagnosis must be made for the seat and character of the lesions. It seems to many practitioners that multiple sclerosis does not so much simulate the psychoneuroses but rather gives rise to the latter, so that the question is not so much one of differentiation as of

finding the underlying organic affection. In other words, we must be on the lookout for a complication of multiple sclerosis with hysteria. To treat a patient with both affections for pure hysteria would be a serious blunder. The victim of multiple sclerosis must be regarded as an invalid who cannot take the liberties granted to a sufferer from functional neurosis. He must lead a sedentary life, which may in part be offset by a Weir-Mitchell cure. Bathing should be with lukewarm water, and not be carried too far. If the medical man can control the case ordinary complete physical therapy may sometimes be tolerated and useful for the moral effect (massage, electricity, etc.). Not much is to be hoped from drug therapy. A graduated arsenic course, radiotherapy, and intramuscular injections of fibrolysin are among the latest remedies advocated.

Psychopathology of Suicide.—Sichel refers to the study of 200 female suicides—*i.e.* attempted cases—by Miss Stelzner. No less than 169 were actual victims of mental elienation, while nearly all of the others showed an exquisite neuro or psychopathic heredity, through which they might well have been temporarily unbalanced. It almost appears from these figures that a purely physiological suicide hardly exists. Gaupp recently analyzed 124 would-be suicides, and found but one with a normal psyche, and she was illicitly pregnant and near term. The mental state of such a woman is hardly well balanced. Finally the author has analyzed 268 patients with suicidal impulses or tendencies. A few imbeciles could be excluded for they did nothing but threaten suicide. In most cases an unsuccessful attempt was recorded, but often possibly not made in good faith, as when a man or woman wished to test the affection of a lover. Contrary to the experience of some writers, the author found hysteria a potent factor. The hysterical subject seemed to make bona fide attempts at selfdestruction, accompanied by all preparations for death. But a few of these women seemed guilty of mere bravado. Their lives are often full of suffering and they shrink not from selfmutilation. Such subjects also make impulsive attempts at selfdestruction as soon as catastrophies occur. Epileptics not infrequently make suicidal attempts, especially during confusional states, and after dementia has set in. Alcohol plays an important and varied rôle in suicidal attempts. One person, resolved to die, may drink to secure the needed courage. Another, of the sort naturally intolerant to the drug, becomes profoundly depressed and seeks to end his life after a debauch. The mental state of some of these men is much like that in confusional epilepsy. The worst alcoholics are much less apt to do violence to themselves than to others. The suicidal impulses of the hysterical, epileptic, and alcoholic lead us naturally to those of pronounced alienation and the psychology of the incompletely alienated in this respect must be at bottom the same as that of the frankly insane. Obsessions, imperative concepts, hallucinations, extreme depression, delusions of persecution, etc., must be present in both. Dementia precox is a fertile source of suicide, although the hebephrenic is not much to be feared in this respect. Paranoiacs are especially to be feared on account of their systematized delusions, and the paranoid type of dementia precox is no exception. These subjects are highly suggestible, and a knife or halter not only suggests its use but causes an imperative concept. In the katatonic form prodromes may be quite absent. The gestation psychoses, whatever their nature, belong in the same class. The attempt at selfdestruction is sudden and imperative, suggested perhaps by the sight of a lethal object. The depressive stage of manic depressive insanity disposes to suicide because of the great mental depression. Dementia of any kind, whether accompanying paresis, arteriosclerosis, or senile involution, exerts a similar influence on the psyche.

Münchener medizinische Wochenschrift.

March 7, 1911.

Influenza?—Under this query Trumpp discusses the varied types of this affection, and concludes that the word may often conceal our ignorance, representing a diagnosis by exclusion. Typical influenza is unmistakable, but the associated affections need not represent vagaries of the disease. In a series of thirty-seven cases, which would seem to represent influenza, but five cases were typical. Thirty had high evening temperatures, but little else beyond a natural loss of appetite for supper. The affection was very short-lived, and the children were often well the next day. The clinical expression of influenza, as the flushed face and eyes, the coryza, etc., was either absent outright or only doubtfully present. There were no pains and the thoracic organs behaved as they should with high temperature, but there was no weakness in evidence. Other organs showed but slight anomalies. The buccal mucosa suggested in certain cases the punctiform redness believed to accompany both influenza and measles. The author believes in the value of Koplik's spots as forerunners of measles, but seems to reject the presence of such lesions as part of influenza. There was some enlargement of the submaxillary lymphnodes. The condition was clearly contagious and had points of resemblance with influenza; yet even the mildest recorded cases of the latter, when seen in epidemics and endemics, are stated by experts to have coryza and conjunctivitis. No trace of Pfeiffer's bacillus was found in eight cases examined. To guarantee a mild case of influenza the latter should at least be in evidence. The author is unable to throw any light on these cases which are wrongly termed influenza, because they may accompany it.

Psychical Disturbances in Chronic Cocainism.—Higier comments on the slight recent literature of this subject. This is due in part to the rarity of cocainism in Germany, whether as a pure vice or associated with other addictions. The alkaloid has been known for fifty years, but has not been used in medicine for more than half that period. Cocaine or rather coca leaves were originally a product of Peru, but for some years Germany has been exporting large quantities. Cocaine is peculiar in that it has a small daily and single dose sufficient to produce its characteristic effects; yet its lethal dose may be very high. We know that cocaine has an affinity for the myelin of the medullary nerve sheaths, like many other drugs which are nerve poisons, and that it can be combined in the spinal cord. We also know that its molecule contains radicles similar to the atropine radicles. The experience of the British colonies shows that the drug is much less toxic to the colored races, especially the destitute, than to whites in good circumstances. A cocainist is not a cocainomaniac, for the former seeks relief from pains not due to the after effects of the drug; while the latter is an addict pure and simple. The cocainist may have been a normal subject, while the cocainomaniac is by birth a psychopathic degenerate, who, however, may be a man of brilliant parts who uses the drug for mental depression. Both naturally suffer from the same withdrawal symptoms, but the prognosis is naturally better for the simple cocainist. Cocainomaniacs include morphinists, morphinomaniacs, hypochondriacs, and neurasthenics. The cocainist has a great disadvantage when compared to the morphinist, because his period of exaltation is very brief, and he is left in a much more helpless condition. Hence the more urgent demand for the drug. Statistics have shown that morphine cocainists have tended to replace their morphine with heroin, the latter being better suited to bridging over the interval between two cocaine intoxications. Cases cited by the author appear to show that cocainism is often confounded with alcoholism and treated accordingly.

Book Reviews.

Makers of Man; A Study of Human Initiative. By Charles J. Whitby, M.D. (Cantab.), Author of "The Logic of Human Character," "The Wisdom of Plotinus," etc., etc. With forty-seven half-tone and other plates. Price, $3.00. New York: Rebman Company.

That the world has always been interested to the point of passion in its great men is an incontrovertible fact the root of which is a noble curiosity. Whence came this light which shines so brightly, which is held so high? From what fount is drawn the strength which dominates, the elixir which creates the supermen? What penalties must greatness pay for greatness, how far have our prophets failed us, and why have we stoned them? "Makers of Men" is the honest endeavor of an earnest thinker to answer these questions. The author starts with the premise that "the lives of great men are problems capable, through and through, of psychological treatment and elucidation," and it is in this spirit that he approaches the study of the forty world-famous men chosen for his experiment. For purposes of classification these are divided into four groups of ten each—the practical, or man of action; the esthetic, or artist; the intellectual, covering both philosopher and scientific discoverer; and the ethical, among whom we find not only the religious pioneer, but also the questioner, so that in this group Jesus of Nazareth and Renan stand side by side—the religious genius and the man whose lifelong preoccupations "were the ultimate problems of life and religion." As the writer points out, this sort of rough class division can only be tentative; all human types merge and interweave in most mysterious ways. A man of action, for instance, who should be *only* a man of action, would soon disclose himself a monster, and the interest he presents to scientific psychology is in just how and why the type is modified in him. Granting all possible modification by heredity, circumstance, or environment, and after every effort to track greatness to its source, our author takes the stand that greatness is an individual manifesation, the most important factor in which is "a central self-conscious aim," but which material science is helpless to explain. "By some divine chance has emerged the world-molding power of a Cæsar or a Charlemagne, the genius of a Titian or Beethoven, the insight of a Goethe, the profound wisdom of a Hegel, the sublime spirituality of a Jesus—all rooted in the abyssmal penetralia of an immemorial past, yet all radiating the authentic luster of a something unparalleled; predestined, yet new." But we must resist the temptation to quote from the wonderful closing chapter in which are disclosed the author's personal views on the subject of human individuality. This is a large and serious work, not to be quoted from, but to be owned and lived with.

The Problem of Race Betterment. By J. Ewing Mears, M.D., LL.D. Philadelphia: Wm. J. Dornan, 1910.

This book contains three articles treating of eugenics, one of which was read at the meeting of the American Surgical Association in Washington in May last and published in the Medical Record August 13, 1910. The question is regarded from the surgical standpoint, and Dr. Mears seems to be in favor of more radical measures to bring about race betterment than either the majority of the medical profession or the public at large would sanction as yet. The case for the asexualization of certain criminals and defectives is well stated.

A Practical Guide to the Newer Remedies. By J. M. Fortescue-Brickdale, M.A., M.D. (Oxon.), Physician to Clifton College, Assistant Physician to the British Royal Infirmary, Lecturer on Pharmacology in the University of Oxford and Clinical Lecturer in the University of Bristol; Joint Author of "The Chemical Basis of Pharmacology." New York: William Wood & Company, 1910.

Of new remedies it may almost be said that there is no end, and it is a task of the greatest difficulty for the busy practitioner to have even a bowing acquaintance with all of them. It goes without saying that the medical practitioner of the present day is, as a rule, imperfectly acquainted with pharmacology and needs a book of reference like the one under review in order to prescribe the drugs prepared in the most scientific manner which he may deem suitable in the treatment of a patient. The aim of this work, as stated in the introduction, is to give some account of the properties and dosage of the principal new drugs in each class, and to indicate their relative and collective value as accurately as possible by reference to clinical experience, laboratory experiment, and a study of the literature. In this attempt the author appears to have been completely successful. In view of the great interest now being evinced in arsenic preparations, the chapter on the cacodylates and the arylarsonates is worthy of close attention. The book may be recommended as a valuable vade mecum to the more important newer remedies.

Gynæcological Therapeutics. By S. Jervois Aarons, M.D. (Edin.), M.R.C.P. (Lond.) With foreword by Sir Halliday Croom, M.D., F.R.C.P., F.R.C.S. New York: William Wood & Co., 1910.

The writer of the present work seems to find fault with the few books on this subject of American origin, in that they devote too much space to the descriptions of surgical procedures, yet he himself so frequently takes occasion to refer to the surgical methods of treatment that one is left in doubt as to the efficacy of many of his own suggestions. The book contains numerous valuable references and methods of treatment, and in most cases abundant prescriptions are presented for the choice of the reader. Fault may be found, however, with certain of the author's directions. Thus, self-medication with vaginal suppositories is not generally regarded with favor, and the use of intrauterine applications has also been largely discarded on account of their general inefficiency and danger. Frequent references are made to the use of mineral waters for douching purposes, a form of medication with which Americans are not very familiar. A very satisfactory chapter is that on the use of the pessary, and reference is also made to the treatment by vaccines and sera. No sharp line can be drawn between medical and surgical treatment in gynecological cases, and although much may be accomplished by the former it should never be regarded as the only method.

Die funktionelle Herzdiagnostik. Von Dr. med. W. Janowski, Privatdozent, Primararzt, leitender Arzt der Abteilung für innere Krankheiten am Kindlein Jesu-Krankenhaus in Warschau. Mit 44 Textfiguren. Price, 4 Marks. Berlin: Verlag von August Hirschwald, 1910.

This pamphlet is one of those useful publications which appear so abundantly from the German medical press, in which our knowledge upon any one limited subject is collated with full references. The bibliography in this particular case includes 731 different papers. After an introduction concerning the problems of functional cardiac diagnosis, there follows a long chapter on the various methods of investigating the pulse, including the use of the sphygmograph, with a discussion of the interpretation of the results, the use of the sphygmograph in connection with blood pressure, and special plethysmographic methods applicable to clinical study. The third chapter discusses the determination of the heart limits by ordinary percussion, by the use of the diaphanoscope, and by radiographic procedures. The fourth chapter takes up the methods of graphic recording of the heart tones, either by the phonograph or by other means. The fifth is devoted to electrodiagrams; the sixth to special procedures, such as the examination of the blood, etc. The volume forms a useful reference work to the literature of the diagnosis of functional activity of the heart.

The Microscopical Examination of Foods and Drugs. A Practical Introduction to the Methods Adopted in the Microscopical Examination of Foods and Drugs in the Entire, Crushed, and Powdered States. By Henry George Greenish, F.I.C., F.L.S., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain and Director of the Pharmacy Research Laboratory; Author of "A Textbook of Materia Medica"; late External Examiner in Materia Medica and Pharmacy to the University of Birmingham. With 200 illustrations. Second Edition. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co., 1910.

Only a few changes and additions have been made in the revision of this very useful and practical book. It remains one of the best of the smaller guides to microscopical examination of drug material, and while it will chiefly interest pharmacists and pharmacologists, yet it may often prove itself useful to physicians studying the morphology of the various vegetable cells found in the feces. Few laboratory men realize, for example, the large number of powders containing the so-called "stone" or sclerenchymatous cells which are so constantly present in the feces of persons on a mixed diet. The numerous excellent wood cuts add much to the elucidation of the text. The appendix gives a list of the useful reagents with the methods of their preparation.

Recherches expérimentales sur les tumeurs malignes. Par le docteur Jean Clunet, ancien interne des hôpitaux de Paris, preparateur d'anatomie pathologique à la faculté de médicine, membre de l'association française pour l'étude du cancer, membre de la société de radiologie médicale de Paris. Paris: G. Steinheil, 1910.

The last ten years have seen a very great change in our knowledge of animal tumors. This has been due largely to the discovery that some of these tumors are readily transferred by suitable methods of subcutaneous inoculation from one animal to another. Active experimental work along these lines may be said to date from Jensen, about 1903, who used a mouse tumor, and discovered a number of facts concerning the methods and results of animal transfers which have since been generally applied by Gaylord, Ehrlich, and Bashford, and the coworkers. This ability to transfer tumors has enabled one to observe very easily the laws governing rate of growth, the incidence of spontaneous recurrences, and the formation of metastases. Another interesting phenomenon which has attracted much attention is the apparently spontaneous transformaion of a carcinoma into a sarcoma, and the reverse. Apparently the epithelial cells of the tumor are able to incite a sarcomatous proliferation in the connective tissue, either that transferred with the tumor or that of the host. In addition to these facts the phenomena of spontaneous cure have been noted, as well as cure following secondary inoculations of the same tumor, or following active treatment with the *x*-rays and radium. It is often forgotten, however, that these phenomena have been observed in healthy animals which have been inoculated with a tumor, which is very different from the case of an animal or a human being who spontaneously develops a carcinoma. The public has been regaled with popular articles describing the results of cures obtained in mice as if the methods of inducing these cures were already applicable to human beings. This is far from true. There is nothing more certain at the present time than that we have no means of curing human malignant tumors except by the knife. Even this simple fact has to be reiterated *ad nauseam*, and the surgeon is still inclined to run after new gods in the form of *x*-rays, radium, serum injections, etc. It is, therefore, very important that monographs detailing experimental researches on tumors, both of animals and of human beings, shall be published. The work under consideration can be divided into two parts: one, on tumors of animals, giving the morphological details of seventeen spontaneous tumors which either were not transplanted or in which the attempt to transplant was unsuccessful. Reports of other experiments concern a statistical study of the percentage of metastases, leading the author to conclude that the surgical removal of a tumor when ultimate cure is not produced favors the development of visceral metastases, a fact which does not seem very extraordinary when one remembers that the removal of the primary growth prolongs life in the human subject often for many years, giving time for the development of such secondary growths. On the whole, the results are the same as those already obtained by Ehrlich and Bashford and other workers in the experimental field. The second part of the book concerns the action of the *x*-rays and radium rays on the tumors of man and animals. It cannot be said that the writer's results are very encouraging, as autopsy protocols are appended to most of the cases. There is also a histological study of carcinomata developing after the action of *x*-rays on the tissues, both of animals and of man. In a rat which had been repeatedly exposed to *x*-rays a sarcoma developed following an ulcerative lesion of the skin. Only one such case is known to have occurred in man, though epitheliomata are not infrequent in those repeatedly exposed to *x*-rays. Such facts must make one hesitate before applying the *x*-rays as a cure to a suspected growth.

Clinical Pathology in Practice. With a Short Account of Vaccine-Therapy. By Thomas J. Horder, B.Sc., M.D., F.R.C.P., Medical Registrar and Demonstrator of Morbid Anatomy (late Demonstrator of Pathology and Junior Demonstrator of Practical Medicine) at St. Bartholomew's Hospital, Physician to the Great Northern Hospital and to the Cancer Hospital, London. Oxford Medical Publications. London: Henry Frowde, Oxford University Press, 1910.

This is indeed a somewhat unusual book, its aim being "to present the practitioner with a brief survey of the scope and usefulness of modern pathological methods as applied to the diagnosis and treatment of disease." Yet it contains less on the subject of pathology than the average textbook on medicine, and also much less technique than the ordinary book on laboratory diagnosis. The author acknowledges even in his introduction that it is not necessary nowadays to remind the physician that laboratory methods are useful; it is rather more important to teach the physician not to neglect the somewhat old-fashioned employment of the patient's history and physical signs in order to make a diagnosis. The first chapter of the book is taken up with a description of a portable collecting case made for the author by a well-known firm, and an enumeration of the reagents and the convenience of the outfit. Then follows some very general information concerning blood cultures, methods of examining blood, etc. The Haldane-Gower hemoglobinometer is recommended. This requires access to coal gas, which in the modern electrically lighted houses may be difficult to obtain, and certainly the apparatus is not so satisfactory as the Sahli. Under eosinophilia no mention is made of the trichina as the inciting agent. While considerable space is devoted to pleural, lung, and lumbar punctures, nothing is said of the examination of the gastric secretion, nor is the value of the ordinary methods of uranalysis considered. In the chapter on "Fever without other physical signs" we read: "In the younger patients precosity and 'being spoilt,' and in those who are older a hopeless love affair are common etiological factors." This important point has, we fear, been omitted from most textbooks on medicine. The work closes with a long section on the treatment of infections by specific inoculations, that is, vaccine therapy, which is certainly, as the author says, "somewhat sketchy and inconclusive." It is difficult to see what useful purpose such a book serves, as the information it contains can be found either in any of the larger textbooks on medicine or in still greater detail in those works devoted to laboratory diagnosis. The topography, binding, and paper are as perfect as the work of the Oxford University Press usually is.

Remedial Gymnastics for Heart Affections Used at Bad-Nauheim: Being a Translation of "Die Gymnastik der Herzleidenden." Von Dr. Med. Julius Hofmann und Dr. Med. Ludwig Pöhlman, Berlin und Bad-Neuheim. By John George Garson, M.D., Edin., etc., Physician to the Sanatoria and Bad-Nauheim, Eversley, Hants. With fifty-one full-page illustrations and diagrams. London: Swan, Sonneschein & Co., Ltd., 1909.

A considerable degree of success has attended the treatment of certain forms of heart affections by means of the Bad-Nauheim natural spring waters and carefully chosen remedial gymnastics. The present book sets forth the treatment in detail. The translation is excellent, and the volume possesses value.

Syphilis: Its Diagnosis, Prognosis, Prevention, and Treatment. By Thomas Pugh Beddoes, M.B., B.C., F.R.C.S. (Eng.), Surgeon to the London Hospital for Diseases of the Skin, Registrar at London Lock Hospital, etc. New York: Paul B. Hoeber, 1910.

Dr. Beddoes has succeeded in showing that an original presentation in a brief form of the subject he has chosen is not an impossibility. He has written a most practical little book, supplementing the usual sum of knowledge about syphilis by many facts gleaned from a rich experience. Treatment especially is well considered by the author, the portions of the book devoted to it being specific in directions and not confined to generalities about the use of mercury and the iodides. We cheerfully recommend the book to the student and the practitioner as the most handy and satisfactory little volume on the subject.

Normal Histology; with Special Reference to the Structure of the Human Body. By George A. Piersol, M.D., Sc.D., Professor of Anatomy in the University of Pennsylvania. Four hundred and thirty-eight illustrations, many of which are in colors. Eighth Edition (rewritten). Philadelphia and London: J. B. Lippincott Company, 1910.

Histology in addition to being an essential part of the medical student's curriculum is also an elementary subject of the course. Oftentimes the medical student is required to take up histology before entering upon his medical student career. Hence, to make histology thoroughly comprehensible, a certain amount of anatomy must be explained. In the work before us this is lucidly effected by pen and pencil. Indeed, the illustrations are very important features of the book, and the whole work is a useful textbook for the student. It is a difficult task to revive an old book, more difficult indeed in many cases than to write an entirely new one. The author of this edition might possibly therefore have done better had he made a new work without reference to the old edition of this one, but he has nevertheless succeeded in making a very good book.

Society Reports

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Annual Meeting, Held January 16, 1911.

The President, Dr. Reynold Webb Wilcox, in the Chair.

A Portable Photomicrographic Camera.—Dr. Robert Lincoln Watkins demonstrated this device. It contained a camera, box and microscope, and both an arc and an incandescent lamp. Dr. Watkins stated that the planning and construction of the apparatus had occupied him for many years. It was always ready for use, and it would photograph any microscopic object. The object could be viewed either in the usual way through the microscope alone, or it could be viewed with both eyes open, on the mirror, without looking through the microscope. The rheostat which necessarily went with the apparatus weighed only a few ounces, and were this not the case the simplicity, practicability, and compactness which had been attained would have been impossible.

Notes on the Surgery of the Prostate Gland.—Dr. Kingman B. Page read a paper with this title.

What is Rheumatism?—Dr. Herbert C. de V. Cornwell read this paper. (See page 577.)

Arthritis Deformans and Its Relation to Intestinal Putrefaction.—Dr. Edward E. Cornwall read this paper. (See page 579.)

Dr. Frank H. Daniels said that in the main he agreed with Dr. Cornwell's conclusions. Rheumatism, as the word was commonly employed, was a most vague term. It included a vast number of conditions which had little in common. Most of these could be assigned to their true causes. Thus, in children one might eliminate all the cases of tuberculous arthritis, in babies the cases of scurvy, and in adults the lancinating pains of tabes. In this way we could finally get down to something that was really scientific. Rheumatism was almost always preceded by some acute attack, and, as had been pointed out, this might be influenza, pneumonia, scarlatina, typhoid fever, or an infected wound. It seemed as though we might consider the painful and enlarged joints met with in rheumatism as symptoms of an infection; but whether we could confine the term rheumatism to one form of infection due to a specific diplococcus was as yet an open question. To his mind it did not seem altogether justifiable to thus limit the disease. He thought it would be preferable to give up the name rheumatism altogether. The difficulty in many instances was to find out where the infection came from. Even now this whole question was in a very unsettled state. The conclusion which he had come to was that rheumatism, so-called, always depends upon an infection, and it behooved us to try to find out what the infection is. As to the treatment, it was a fact that the results obtained fifty years ago by Flint, with his palliative methods, were just as good as those of Osler to-day, with the most modern treatment. The cases in which the salicylates were successful were those resembling gout, in which there was a chemical, rather than a bacterial, etiology.

The Surgical Treatment of Arthritis Deformans.—Dr. Fred H. Albee said that, in view of the number of papers on the program of the evening, he would devote his attention to the consideration of the treatment of arthritis and similar conditions of the hip only. While he would be unable at this time to add much to what he had already published, he hoped that a later report of results and of the extension of the field of the operation which he had developed, with some minor alterations in technique, might prove of interest. He had performed the operation in twenty-one cases, and sufficient time had now elapsed to enable him to report final results with certainty. Moreover, without any special effort on his part to secure such records, sixteen surgeons had informed him that they had done the operation successfully one or more times. From these reports and his own experience he had become entirely convinced that the field of this procedure was as wide as that of excision of the knee, to which he regarded it a perfect analogue. Further than this, he believed that the hip was a joint far preferable to the knee to stiffen. Having given his reasons for this opinion, he said it was not necessary to dwell upon the serviceability of a non-sensitive hip ankylosed, in good position, from any cause. The relief of pain was always the most important consideration in these cases. Of twenty-one cases, seventeen had been arthritis deformans, and in five of the seventeen the process had begun under the age of twenty-five years. Contrary to the statement of most writers on the subject, monarticular arthritis deformans of the hip began in a large percentage of cases in the young or middle-aged, and therefore the term "senile coxitis" was distintly a misnomer. The method of reaching the hip by a U-shaped lateral incision and turning up the great trochanter he believed to be preferable only in very fat subjects, and he had tried it on the cadaver only. In all his cases he had employed an anterior straight incision five or six inches long, starting from just below and inside the anterior spine of the ilium and extended downward. The sartorius and rectus femoris muscles were retracted outward, the iliacus and psoas magnus pulled inward, and all the deeper muscles and structures separated by blunt dissection. If osteophytes were present on the rim of the acetabulum, they were turned up with the soft tissues attached, and preserved for their bone-producing possibilities. That part of the acetabulum overhanging the head was next removed with a chisel; thus exposing the head and facilitating the removal of its upper part. Approximately one-half the upper capital head was removed with a large chisel, through a plane as nearly parallel with the long axis of the femoral neck as possible. The portion of the head which had been removed was then, by means of a small osteotome, split, *in situ*, at right angles to its cut surface, into small segments, and these fragments extracted with a curette or strong clamp. This exposed the under articular surface of the upper part of the acetabulum to sight or palpation with the tip of the finger. Enough of the head should always be removed to allow the finger to be placed well into the joint, and in fat subjects it was necessary to rely almost entirely upon touch alone. The upper part of the acetabulum was transformed by means of a chisel and curette into a flat surface; against which the flat surface of the head was finally approximated by abduction of the thigh. After the removal of the upper portion of the head the femur was strongly rotated outward, and all the cartilage which could be reached on the anterior aspect of the remaining portion was removed with a chisel. The instrument was next inserted between the head and the acetabulum, and the cartilage on the contiguous surface of the acetabulum destroyed as far as possible, with the hope that, in the presence of an already partially disintegrated cartilage, an ankylosis in two planes at right angles to each other might result. On account of the frequent puncturing of rubber gloves by sharp edges of bone, the speaker, at the suggestion of Mr. Robert Jones of Liverpool, had placed thin cotton gloves over the rubber ones in his later cases After the operation it had been found imperative to take every precaution to prevent a recurrence of the adduction deformity. Tenotomies of the adduction muscles and tendons were done, and both thighs were enveloped in double plaster-of-Paris spicas (extending on the operative side to the toes and on the other to the knee), with both limbs in abduction. To prevent binding of the plaster a U-shaped piece of strong brace steel was incorporated under the last few bandages. This was cut out of the spica

when the plaster was removed from the well thigh, at the end of ten days to two weeks. The long spica on the operated side was cut off just below the knee at the end of five or six weeks, and this short spica, or some other means of preventing adduction, should be continued for three or four months. Dr. Albee believed that the field of this operation should be extended to include all conditions which, if they existed in the knee-joint, would be rightly treated by an excision.

Dr. Henry Ling Taylor said that these cases of osteo-arthritis of the hip had long been the despair of both physicians and surgeons. There was no reason to believe them due to an infection; they seemed rather to be ascribable to a disturbance of nutrition. The pain experienced was due to the rubbing together of the bony surfaces, and the object of treatment was to prevent motion. Of course, it was not every case that was to be operated upon, as some cases were of a mild type and could be rendered by palliative treatment. But in some instances the suffering was severe, rendering work impossible, and here heroic measures were called for. We could prevent motion either by operation or by the employment of a splint, but very few adult patients were willing to put up with the inconvenience of wearing a hip splint indefinitely. Personally, he had performed the operation described in the paper three times, with the assistance of Dr. Albee. It was a fairly difficult and somewhat tedious procedure, and it would be wise to perform the first operation on the cadaver. Excision of the head of the femur had been done for the relief of this condition, but as a rule, it had not proved satisfactory, and he considered Albee's operation decidedly the best that had as yet been devised.

Tendon Transplanting.—Dr. Reginald H. Sayre said that tendon transplantation for restoration of function after traumatism seemed to have been first practised by Missa, who reported in the *Gazette Salutaire*, No. 21, 1770, a case in which the tendon of the middle finger having been severed, with inability to suture it, the proximal end was implanted into the tendon of the index finger and the distal end grafted into the tendon of the ring finger. Champion grafted the tendons of the little finger and of the ring finger in a case where he removed the little finger and its metacarpal bone. In 1874 Polaillon reported a case where the patient had ruptured the three middle extensor tendons of one hand and the central ends were retracted beyond the possibility of suture; and to remedy the condition he attached the distal ends to the tendons of the thumb and little finger. It was not until 1881, however, that this method of treatment was suggested for the relief of disability caused by paralysis. At the annual meeting of the Society of German Naturalists and Physicians in that year Nicoladoni showed before the Surgical Section a sixteen-year-old boy on whom he had operated for paralytic talipes calcaneus by sewing the tendons of the peroneus longus and brevis into the tendo Achillis. But this operation seemed to have attracted little notice, possibly because of the unfavorable selection made by Nicoladoni for his procedure, as the combined bulk of the peronei was very much less than that of the soleus and gastrocnemius, whose function it was tried to make them fulfill. Therefore, when Parrish, in October, 1893, reported a case of anterior tibial paralysis in which he had sewed the tendon of the extensor proprius hallucis to the anterior tibial tendon, it was thought to be a new principle in surgery. In the same year Drobnik, a Polish surgeon, reported sixteen cases of paralysis in which he had operated; one of them being in the upper extremity, in which the extensor carpi radialis longior was transplanted upon the extensor communis digitorum, with the result that the patient obtained some use of his fingers. In 1894 Goldthwaite of Boston published extensive researches on this subject, and Franke reported a series of operations in cases of spastic paralysis; previous operators having confined themselves to paralysis of the flaccid varieties. Eulenburg of Berlin was the first neurologist to bring this operation into notice; reporting a case of cerebral diplegia on which operation had been done, and urging a more general application of the theory, so as to include all sorts of paralysis. More recently Vulpius and Lange had brought this operation very prominently before the profession. As the tendon, when transplanted to another tendon, not infrequently gives way, it had been suggested that it should be fastened to the periosteum of the bone which it is desired to move, and as it is often too short for this purpose, Lange advised lengthening the tendon by means of a cord of sublimated silk. In order for this procedure to be successful certain details were essential: (1) The live muscle utilized to take the place of the paralyzed one must be sufficiently large and in a sufficiently healthy condition to do the work required of it; (2) the tendon must be so transplanted that the muscle may act in a direct line along the course in which it is desired to move the bone; (3) the tendon must be united in a position of great tension as otherwise a larger amount of slack will exist between the contracted muscle and the bone to be moved; (4) this position must be maintained during healing by a stiff splint, so as to relieve the sutured tendon from strain; (5) the strictest asepsis must be observed or the operation will fail. It was in comparatively few cases, Dr. Sayre said, that the necessary conditions were present to justify the operation; but, giving a strong muscle in the neighborhood of the paralyzed one of equal force, these operations had been of great service in paralysis of the foot. In paralysis of the knee joint the hamstrings or the sartorius might take the place of the paralyzed quadriceps. In the upper extremities the flexors and extensors of the hand had been transplanted with advantage. Operations about the shoulder seemed to be of little value. In cases of feeble muscles but little was to be gained by tendon transplantation, as the tightened tendons simply served to restrict to a certain extent the motion of the flail joint which could probably be better done by an arthrodesis.

Dr. T. Halstead Myers said it had been argued by some that extensors could not be made to perform the office of flexors, and the reverse, but this had been disproved by the success attending numerous operations. In performing the operation the esmarch was of great assistance. He had personally made use of the silk treated with bichloride and coated with paraffin, and had never had any untoward results from the procedure.

Dr. Russell A. Hibbs said that at first surgeons were very enthusiastic over the transplantation of tendons and muscles. He was free to confess, however, that after four, five, or six years, in cases which he had followed up, he had not observed very much gain to the patient. Arthrodesis seemed to him decidedly preferable. It was questionable, he thought, whether we gained enough to sacrifice a good muscle. As to the operation in the upper extremities, as had been performed in cases of infantile paralysis, he had never observed results sufficiently satisfactory to justify the procedure, and consequently he had not personally resorted to it.

Dr. Cornwell, in closing, said it was undoubtedly the case, as stated by Dr. Daniels, that there were various infections preceding the symptoms of rheumatism. The point that he wished to bring out was that there was a distinct form of disease which possessed certain specific characteristics peculiar to itself, and he would call this rheumatic fever. He quite agreed with the proposition that the term rheumatism should be banished entirely from our nomenclature.

Dr. Cornwall thought that the use of the word rheu-

matism should be confined to rheumatic fever, which, like Dr. Cornwell, he believed to be a specific infectious disease.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY

Stated Meeting, Held January 6, 1911.

DR. GEORGE WOOLSEY IN THE CHAIR.

Three Cases of Papillary Growth of the Bladder Removed by High Frequency Current (Oudin).—Dr. EDWIN BEER presented these cases to illustrate the efficiency of the high frequency current. The technique of the operation which he described last year in the *Journal of the American Medical Association*, was very simple, painless and efficient, requiring only experience in its management. The first case presented was a woman, eighty-two years old, who had a papilloma of the bladder larger than a silver dollar. At the first treatment there was some hemorrhage. The tumor surrounded the right ureter and its removal by any surgical procedure was out of the question. The growth was treated by high frequency current with an electrode especially made for the purpose. The electrode was introduced directly into the tumor. She was given a seven minutes' treatment and this was followed by a total necrosis of the growth. After one month there remained only a very small piece; soon after the bladder became absolutely normal, with perfect function except for a slight increased frequency in urination. The second patient presented was a woman, sixty-six years old, who possessed a smaller tumor than the first patient had; it was a polypoid mass. She was treated for a similar length of time, was absolutely cured, and had remained cured for eight months. She had about four séances with the high frequency current. An interesting feature in this case was that she came to the hospital practically exsanguinated. Within twelve hours after admission, the hemorrhage ceased; the hemoglobin percentage went from 30 to normal in a short time. The third patient presented was a man who had the most extensive tumor Dr. Beer had ever seen; its appearance suggested the possibility of carcinoma. After treatment with the high frequency current the whole tumor disintegrated and was thrown off. This tumor occupied about one-third the whole bladder and involved the left ureter. Dr. Beer said that the term "fulguration" was a misnomer as applied in the treatment of these cases. His cases were treated through a water medium. The so-called "fulguration" was applied to the treatment of cases of carcinoma after the institution of surgical measures and was followed by sparking. Such could not occur under water media and, therefore, the name was a misnomer.

Bullet Wound of Chest and Spine; Paraplegia; Laminectomy; Tenotomies; Recovery.—Dr. JOHN J. MOORHEAD presented a man, forty years old, who was admitted to the hospital last August after having been shot in the eighth left interspace with a 38-caliber bullet; the bullet passed downward and backward and to the second lumbar vertebra. There was much shock, dyspnea, and cough, with signs of a pneumothorax. Both limbs became paralyzed, and he was unable to control the abdominal muscles. The sensory disturbances were marked; there was loss of the sense of touch, pain, and temperature below the left Poupart's ligament. The knee-jerks were absent. The sphincters were normal in action. The patient was operated upon September 3; a laminectomy was performed on the last two dorsal and the two upper lumbar vertebræ. There was found a fracture of the second lumbar vertebra with a fragment which pressed upon the dura. There was also an extradural clot. When the dura was opened there was a gush of blood-stained fluid. There appeared to be no destruction of the cord substance itself. Three weeks after the operation there was considerably less loss of the sense of touch, pain, and temperature over both thighs and legs. The knee jerks were still absent. In October there was a gradual improvement and on the 19th the patient was discharged from the hospital. He returned, however, in June, 1910, and was operated upon for a persistent foot drop. Later he returned to the hospital and was operated upon for a double toe drop. He now had perfect motion and control of his thigh and leg muscles.

Diverticulum of the Esophagus.—Dr. EDWARD W. PETERSON said he had reported a case of diverticulum of the esophagus at the October meeting of the Section; the patient, a man, was operated upon on the day of the meeting. Now he presented a woman, sixty-six years old, with a similar condition. She had had asthma and bronchitis for many years. About twelve years ago she had some operation performed upon her nose; this was followed by cocaine poisoning and she dated her present trouble from that time. She had great difficulty in swallowing. Five years ago she began to regurgitate. She had dysphagia and there was an increasing and persistent amount of regurgitation. At times she was unable to swallow anything, not even fluids. A physician whom she consulted in the country pronounced her condition to be one of carcinoma. She came to the hospital in September with the history of long-standing dysphagia, persistent regurgitation, and with a sense of fullness in the neck. With the aid of a bismuth paste and the *x*-ray a diagnosis was made of diverticulum of the esophagus. The pouch could be easily seen in the picture shown by Dr. Peterson. At operation the pouch was found to be at the junction of the esophagus and pharynx; it was clamped and cut away; the defect was sewn over with a ten-day No. 2 chromic catgut. A good recovery followed and she had no more dysphagia since operation.

Undescended Testicle (Torek Operation).—Dr. EDWARD D. PETERSON presented a boy, eight years old, whose left testicle had never descended. A lump appeared in the left groin and a physician applied a truss which gave him much pain. At operation (Torek's) he found the testicle at the internal ring and it was very small. The truss that had been applied had pressed directly upon it. The patient left the hospital at the end of two weeks with as good a result as one could wish.

Two Cases of Prostatic Hypertrophy Successfully Treated by X-Ray and High Frequency Current.—Dr. L. SINCLAIR TOUSEY presented these patients to show the effect of the treatment, the application of the *x*-ray over the perineum, without the tube in the rectum and with a sole-leather screen; the use of the latter absorbed the rays which would have been absorbed by the skin. The high frequency current was applied as well. The first patient was seventy-three years old, and had much difficulty in micturition, having had to resort to the catheter for a long time; he was compelled to give up its use because it caused him so much distress. For ten or twelve years he had difficulty in urinating and got up as often as twelve or fourteen times at night. Occasionally he had rather severe tenesmus. After treatment for three weeks he only had to get up two or three times at night and was in apparently a normal condition. The second patient was seventy-three years old and had been treated for years for enlargement of his middle lobe; operation was advised for his prostatic hypertrophy. Under treatment with the *x*-ray and high frequency current the amount of residual urine was reduced from eight to four ounces. The use of the catheter had been discontinued and he went eight hours at night without urinating.

Ileocolic Intussusception with Resection of Twenty-two Inches of Gangrenous Gut.—Dr. W. S. SCHLEY presented a girl, six years old. Six days before he was called she was taken ill with abdominal cramps and vomiting.

She was fairly nourished. There were signs of fluid in the abdominal cavity, and her right rectus muscle was more rigid than the left. There was a mass over the seat of the caput and ascending colon. Her temperature on admission was 101° and the pulse 120. A diagnosis was made of intussusception and operation performed. The intestine was very gangrenous and it was necessary to remove twenty-two inches of it. The button was passed on the seventh day. Vaccines were used but without any effect whatever. The child was placed out of doors. The blood cultures proved to be negative. She developed extreme sepsis but recovered gradually and was in perfect health now.

X-Ray Plate of a Brass Screw Lodged in the Right Bronchus; Removed by Operation.—Dr. W. S. SCHLEY showed this plate. The brass screw had been swallowed three days before he operated. The child was eighteen months old. The patient was placed in a one-half Trendelenberg position and a low tracheotomy performed under slight chloroform anesthesia.

Intercostal Diaphragmatic Hernia.— Dr. J. A. C. GERSTER presented a man who had an abrasion of the knee; when at the hospital there was found accidentally a mass on the left side of the thorax which proved of interest. It was reducible and, on deep inspiration, it made excursions; sometimes gurgling was noticed. This mass he had had for three years. He worked in a sawmill and was struck by a plank in the region of the hernia. It gave him no trouble and he enjoyed perfect health. He now was a longshoreman and did a good day's work. The tumor had not grown any larger and he was not inconvenienced by it at all. This man had been observed at the clinic of Bellevue and University Hospital and Medical College.

Intestinal Resection for Strangulation by Adhesions.—Dr. C. R. L. PUTNAM presented this patient because she had points of interest both as to diagnosis and pathology. She entered the hospital when four months pregnant; she claimed that she had vomited every time she ate or drank from her second week of pregnancy. She was very pale and so weak that it was impossible to count her pulse. She was in extreme shock. The middle of her abdomen was tympanitic and the hypogastric region was prominent. The right flank was dull on percussion. There was tenderness over the right lower quadrant of the abdomen. The vaginal examination showed a boggy mass on the right side. There was no vaginal hemorrhage. The diagnosis lay between a tumor with a twisted pedicle complicating pregnancy, an internal hernia, and an ectopic without hemorrhage. At operation four or five coils of small intestine were found to be strangulated under a band back of the cecum. This band was extremely tense, almost like a whip cord. When cut there was an improvement in the color of the bowel. Portion of the bowel was removed together with necrotic mesentery, and a Murphy button used which was passed on the seventh day. The strangulation appeared to have been formed by a reverse peristalsis through a small loop formed by this hand and the mesentery. The five coils of intestine measured about six feet. The proximal end was near the beginning of the jejunum; the distal end had the character of the beginning ileum. The patient made a good recovery.

Experimental Study of the Effects of the High Frequency Current (Oudin) on Prostatic Hypertrophy.—Drs. EDWIN BEER and A. HYMAN made this preliminary report, stating clearly that their work was purely in the experimental stage; they were of the opinion, however, that through treatment with these currents they might eventually produce a complete cure of cases of prostatic hypertrophy. So far they had obtained marked relief of some of the most annoying symptoms, together with objective changes in the prostatic gland. Up to date they had treated six cases which they reported in full. They employed the Oudin current just as originally described. The current had been applied to the prostate either through the anterior rectal wall or through the posterior urethra. In the former case the electrode was applied through a Kelly cystoscope or alongside of the finger after thorough insulation; in the latter case the electrode was introduced through a Buerger urethroscope with alypin anesthesia. Both methods were practically painless. In summarizing the review of the histories of the six cases reported they concluded that the high frequency current (Oudin) exerted a decided influence upon the symptoms of prostatic hypertrophy and induced objective changes in the prostate gland which were readily detected. Palliation of distressing symptoms was fairly regularly obtained and, in some cases, the end result suggested the possibility of a cure. Further work along these lines must be done to determine a great many points that suggested themselves; in the course of a few years they hoped to know how regularly they could get relief by the means described, and also how much permanent relief would follow.

Dr. A. HYMAN said he was truly astonished to see the reduction in the size of the tumors from time to time. All of the cases showed a steady diminution in the amount of residual urine, in some cases from complete retention of from fourteen to sixteen ounces down to two or three ounces. A strange feature seemed to be that the applications made to the rectal and urethral walls were practically painless; when the same current was used on the skin there was severe pain. From what they had seen so far it would seem that it was rather dangerous to apply the copper electrode to the rectal wall for longer than two minutes; in one case an application for two and a half minutes caused a violent reaction. Intraurethral methods should be shorter; twenty to forty seconds seemed to suffice in most instances. Just how long it was necessary to apply the treatment was still not settled; one application every two or three weeks would probably suffice.

Dr. EDWARD L. KEYES, Jr., wondered if there was any danger in using the current, as Dr. Beer had, of doing harm to the bladder wall. He had used a similar current which apparently burned. Applications were made by Dr. Beer through the rectum; Dr. Keyes asked if that did not cause a burning of the rectal wall.

Dr. BEER replied that it did.

Dr. JAMES PEDERSEN believed that one should be very cautious in drawing even tentative conclusions from reports of such a small number of cases. Cases of prostatic enlargement behaved in curious ways and wonderful effects upon such hypertrophies had been reported by means other than those outlined by Dr. Beer. For instance the use of nitrate of silver would produce effects equally as surprising. Such patients, he believed, should be treated from time to time to prevent relapses.

Dr. LEO BUERGER said he had had considerable experience with the high frequency current, especially with its use in the bladder. He agreed with Dr. Pedersen that many cases of prostatic hypertrophy would get well apparently upon the slightest interference, and one should be very careful in attempting to draw any definite conclusions especially from the results of such a small number of cases as had been reported.

Dr. BEER said that the presentation of the paper was in the nature of an experimental study of the effects of the high frequency current in cases of prostatic enlargement.

Abdominal Contusions.—Figueira states that statistics and reports show beyond a doubt the brilliant results of prompt operative interference in these cases at the earliest possible moment. Once infection has set in the case is beyond help of any kind.—*Long Island Medical Journal.*

Medicolegal Notes.

Maryland Medical Registration Law Held Constitutional by United States Supreme Court.—The Supreme Court of the United States has held that the medical registration law of Maryland (Act 43, § 83, Code of 1904) is not unconstitutional as denying equal protection of the law because its provisions do not apply to those who practised prior to a specified date and treated at least twelve persons within a year prior thereto, or because it does not apply to gratuitous services, or to physicians in hospitals, none of the exceptions being unreasonable. Dealing with the well-settled fact that the police power of the States extends to the regulation of certain trades and callings, particularly those which closely concern the public health, the court said that there is perhaps no profession more properly open to such regulation than that which embraces the practitioners of medicine. Dealing, as its followers do, with the lives and health of the people, and requiring for its successful practice general education and technical skill, as well as good character, it is obviously one of those vocations where the power of the State may be exerted to see that only properly qualified persons shall undertake its responsible and difficult duties. To this end many of the States of the Union have enacted statutes which require the practitioner of medicine to submit to an examination by a competent board of physicians and surgeons, and to receive duly authenticated certificates showing that they are deemed to possess the necessary qualifications of learning, skill, and character essential to their calling. In such statutes there are often found exceptions in favor of those who have practised their calling for a period of years. Such exceptions proceed upon the theory that those who have acceptably followed the profession in the community for a period of years may be assumed to have the qualifications which others are required to manifest as a result of an examination before a board of medical experts. In the statute under consideration the excepted class were those who had practised before the first of January, 1898, being more than four years before the passage of the law, and who could show, presumably, with a view to establishing that they were actively practising at that time, that they had treated at least twelve persons within one year of that date. Conceding the power of the legislature to make regulations of this character and to exempt the experienced and accepted physicians from the requirements of an examination and certificate, the details of each legislation rest primarily within the discretion of the State legislature. With regard to the exemption of resident physicians, or assistant physicians, at hospitals, and students on hospital and dispensary duties the court said that the selection of the exempted classes was also within the legislature power, subject only to the restriction that it be not arbitrary or oppressive and apply equally to all nersons similarly situated. The court could not say that these exceptions nullified the law. The reason for them might be that hospitals are very often the subject of State or municipal regulation and control, and employment in them might be by boards responsible to public authority under State law or municipal ordinance.—Watson v. Maryland, 218 U. S. 173.

Exhumation and Dissection of Body Not Permitted in Accident Case.—A novel application has been made in an action by the administration of a deceased person, whose death was alleged to have been caused by injuries received in a collision with an automobile claimed to have been owned by the defendant. The certificate of death signed and filed by the attending physician stated the cause of death to have been malignant endocarditis. The defendant petitioned for an order of the court giving the defendant a discovery and inspection and permission to take cultures of the body, and to examine the contents thereof by microscope and other aids to scientific men. The petition stated that the disease known as malignant endocarditis is a disease affecting the interior of the heart, is caused by a germ or septic condition of the blood, and usually results from causes which are in no way attributable to injuries received in an accident, and that an examination would determine the precise cause of the disease which produced death. The defendant based his claim upon New York Code Civ. Proc., § 803, as amended by laws 1909, c. 173, so as to authorize the court to compel a party to an action to make discovery of any article or property under his control in addition to the power to compel inspection of a book, document, or other paper as originally conferred. The court, however, denied the motion, stating that it did not believe that the legislature had any intention to include the body of a dead person within the description of an "article" or "property". It held that in view of the Penal Law (Consol. Laws c. 40) § 2210 *et seq.*, prohibiting dissection except as authorized by law, and prohibiting the removal of a buried body without authority of law, etc., the court was not authorized to order the production and inspection of a dead body. Moreover, if section 803 were to be construed as authorizing such an order there is nothing in the section which could possibly authorize the dissection of a buried human body and an examination of its contents.—Danahy v. Kellogg, 126 N. Y. Supp. 444.

Medical Expert Opinion as to Effect of Whipping on Vital Powers.—Medical experts are permitted to give their opinions that certain instruments are such as would produce death, as well as that certain wounds were inflicted by certain instruments. In a prosecution for the murder of a child of two years old the State's theory was that the child had been whipped in such a way by the accused that a blood vessel in the brain had burst. A physician was allowed to testify that in his opinion the whipping would have the effect to weaken the vitality and lower the resistive powers of the deceased, and thereby render her more liable to the bursting of a blood vessel on the brain. —Betts v. State, Texas Court of Criminal Appeals, 133 S. W. 251.

Medical Expert Witness Fees.—Consolidated actions were brought by three physicians and surgeons against the defendant to recover for professional services as expert witness for three days in two cases and four days in the other. At the request of the defendant and her attorney, the plaintiff had made a physical examination of the defendant and at her attorney's request had attended court and given evidence of their opinion relative to her condition, and the causes which might have produced it, in an action for personal injuries brought by her against a railroad company. The plaintiffs rendered a bill of $50 per day. The defendant contended that they were only entitled to ordinary witness fees of $1.50 per day. The jury allowed them in their verdict $37.50 per day, and this was affirmed on appeal. The court said: "It will be observed that the question raised is not whether an expert witness can be summoned into court in the regular way, and be required to give in evidence all the knowledge he may have acquired as an expert upon a particular subject under investigation, for the regular witness fee, but whether, having been employed by a party to give special attention to the investigation of a matter out of court, and then to appear in court, not only to testify as an expert witness, but to remain in court for a specific length of time with loss of regular occupation, not by order of the court, but by the request of the party employing, a witness is entitled to receive reasonable compensation beyond the regular witness fee for such services. * * * A witness under subpœna after testifying for an hour or half an hour might be excused by the court and enabled to pursue his ordinary occupation, instead of losing three days. He is under no contractual obligations whatever to the party calling him. He cannot even be unwillingly interviewed before testifying. He takes the stand, testifies and leaves it. This is all he is required by law to do. The court, of course, could require him to remain in attendance, but it is an unusual case in which an expert witness, capable of earning perhaps $100 per day, would be required to remain at $1.50 per day for the benefit of private interests. Hence it appears that a witness summoned into court, and for nonappearance subject to contempt, stands in an entirely different relation to the court and the parties from the witness who appears in court without summons, but upon a special agreement not only to prepare and testify, but to remain in court for the special benefit of the party calling him. Such a witness performs services outside the statutory requirement, and is entitled to whatever his services are reasonably worth above the legal fee due to the ordinary witness."—Gordon vs. Conley, Maine Supreme Court, 78 Atl. 365.

Medical Expert Testimony as to Cause of Rupture.—On a trial of a teacher for the murder of a pupil by excessive punishment, a medical expert testified that upon the post-mortem examination of the deceased he found her bladder in a ruptured condition, and that in his opinion rupture of the bladder was the cause of her death. He further testified that he found an abrasion of the skin on the abdomen over the region of the bladder. It was held that the court properly permitted him to give his opinion as an expert that the same force which caused the abrasion caused the rupture of the bladder, as the subject was one about which a medical expert could speak more advisedly than any other witness.—Johnson v. Commonwealth, Virginia Supreme Court of Appeals, 69 S. E. 1104.

Books Received.

The Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week of March 25, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	660	205
Diphtheria	324	29
Measles	682	19
Scarlet Fever	636	23
Smallpox	1	—
Varicella	216	—
Typhoid Fever	30	7
Whooping Cough	118	4
Cerebrospinal Meningitis	13	7
Malarial Fever	—	—
Totals	2,680	294

Experiments with Anaphylaxis of Gastric Juice.—Spiro Liverato experimented as to the effect of gastric juice from persons afflicted with cancer of the stomach and of other organs injected into the subdural region of guinea-pigs. The gastric juice was obtained from two cases of cancer of the uterus, one of cancer of the right thigh, and one of gastric cancer. He found that the gastric juice of the patients having cancer in other regions than the stomach injected into healthy pigs gave no effect of anaphylaxis. Neither was there any effect when the animals had been prepared by injections of extract of mammary cancer. But the gastric juice from the case of gastric cancer caused death when injected, and if injected into prepared animals caused anaphylaxis. Thus we see that the juice of patients having cancer in other parts of the body does not cause anaphylaxis, but that the juice from a stomach having gastric cancer does cause it.—*Annali dell' Instituto Maragliano.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 24, 1911.

POSTURE AS AN AID IN THE DIAGNOSIS AND TREATMENT OF CARDIAC AFFECTIONS AND DROPSICAL CONDITIONS OF VARIOUS ORIGIN.*

BY HENRY W. BERG, M.D.,

NEW YORK.

ATTENDING PHYSICIAN TO THE WILLARD, PARKER AND RIVERSIDE HOSPITALS; ADJUNCT ATTENDING PHYSICIAN TO MT. SINAI HOSPITAL, ASSOCIATE IN PEDIATRICS, COLUMBIA UNIVERSITY.

PATIENTS suffering from various surgical and medical diseases have always recognized the efficacy of assuming postures of the body favorable to the relief of many of the symptoms of disease. Indeed, some diseases enforce the assumption, consciously or unconsciously, of strained positions of the body and limbs, as, for instance, the characteristic position of the head, chin, and neck in cervical and dorsal Pott's disease, in order to relieve pain and muscular spasm; the support of the body on the healthy leg in the case of disease of one of the hip joints, etc. So characteristic and specific are these postures in various conditions that they play a very important part in the diagnosis of many diseases, both surgical and medical. Thus the picture of a patient suffering from peritonitis lying on the back with the thighs flexed on the abdomen is classical. These positions, symptomatic of various diseases, are frequently adopted by the therapeutist in the treatment of those diseases. In other cases a knowledge of the pathology of various affections has taught the physician to put the patient in postures most favorable to the cure of his malady. These latter positions are not instinctively assumed by the patient, but are none the less efficient in that they place the diseased part in the position most favorable for the cure or relief of important symptoms. Enforced positions for the patient are practised as aids in the recognition of pathological conditions, *e.g.* in chest effusions in the differentiation between the flatness produced by them and the flatness produced by pulmonary neoplasms: physicians here seek aid in diagnosis by displacing the area of flatness, as happens in turning the patient far over to the opposite side; the fluid then sinks to the opposite side, displacing some of the area of the flatness by pulmonary resonance. In neoplasms of the lung no such displacement would occur.

Although the most obvious applications of posture, instinctive and enforced, for the diagnosis and treatment of disease occur in surgical affections, yet even a cursory consideration of the subject will recall many instances of the application and practice of this principle in medical conditions; as, for examples, the use of the Trendelenburg position for patients fainting from cerebral anemia; the reversed Trendelenburg for patients suffering from pneumonia and pleurisy with effusion, which acts by drawing down the liver by gravity and with it the diaphragm, and thus increasing the intrathoracic space; the treatment of pelvic and lower abdominal peritonitis by the Fowler position to prevent infection of the upper general peritoneal cavity, etc. Cooper[1] says that he has cut short an attack of biliary colic by causing the patient rapidly and suddenly to assume the knee-chest position, and suggests the relief of right-sided renal colic by having the patient lie on his right side with the head elevated, thus causing the stone to fall back into the pelvis of the kidney. Cooper also suggests the relief of simple dilatation of the stomach by the patient lying on his right side with the foot of the bed raised to encourage the gas to pass through the cardiac orifice and the fluids through the pylorus. The use of postural treatment, that is, the frequent changing of the position from one side to the other, is a frequent resort to prevent hypostatic congestion of the healthy pulmonary areas in pneumonia and to prevent pulmonary hypostasis in typhoid, measles, and other inflammatory conditions involving weakness of the right heart. The prevention of decubitus by changes in posture in typhoid patients is an application of the same principle. Absolute rest amounting almost to immobilization in a favorable posture, enforced in the thrombophlebitis of typhoid fever, is an application of the rest posture in medicine, comparable to the rest posture in the early stages of treatment of bone fractures in surgery.

A. Keith[2] calls attention to the use of the left sided recumbent posture in auscultating the heart sounds to clarify the diagnosis in doubtful cases. This is the simplest application in the use of posture in the diagnosis of cardiac conditions. The instinctive demand on the part of the patients suffering from advanced cardiac disease for the semi-erect or entirely upright posture (high back support, sitting, or even standing position) and the absolute concession of the physician to the demands of his patient, however much he might otherwise have preferred to advise a recumbent posture for a diseased and weakened myocardium, have long impressed me with the fact that the postural treatment of cardiac conditions is of vital importance. The application of such postural treatment is not simple. On the one hand a weak myocardium and insufficient cerebral circulation demand recumbency. On the other hand, the most urgent need of the organism as voiced by the patient, "I can't breathe when lying down" and "I breathe better when sitting up or standing," indicate an erect or semi-erect posture. It will not be necessary, therefore, to apologize for bringing to your

*Read before the Medical Society of Greater New York at the meeting held February 20, 1911.

attention some studies made with the object of determining the principles that govern the use of posture in cardiac affections, and some applications of these principles which I have practised.

Much work has been done by various observers, particularly by W. Gordon,[3] and also by A. Keith, to determine the changes which result in the position of the heart during the erect as compared with the "flat-on-the-back" recumbent posture. In the erect posture the relative position of the heart with regard to the other contents of the chest cavity undergoes modifications from its position in the recumbent posture owing to two causes: first, increase in size of the chest cavity, and, second, the action of gravity. Gordon shows, and he quotes other observers in confirmation, that in the upright position the mid anteroposterior diameter of the chest at the level of the nipple is increased by half to three-quarters of an inch in adults, and correspondingly at all ages, beyond that of the anteroposterior diameter in the recumbent posture. I believe that this is partly due to the increased convexity of the dorsal spine in the standing position and because the weight of the body in the recumbent posture flattens out the posterior section of the chest wall. This gain of half to three-quarters of an inch in the depth of the chest cavity in upright position is equivalent to an increase of the space occupied by the heart, in the standing position, of one-sixth of its depth (anteroposterior measurement). Furthermore, the force of gravity pulling the liver and spleen, as well as the full stomach, bowels, and diaphragm downwards, largely increases the longitudinal diameter of the thoracic space occupied by the heart during the erect posture. In recumbency not only is this positive increase in space lost, but the bowels and stomach when filled with gases have a tendency to rise to the top (anterior abdominal wall) and thus push up the liver, other organs, and diaphragm and cause them to encroach upon the thoracic space occupied by the heart. In addition I have found by percussion in the erect posture the apices of the lungs rise higher above the first ribs, the heart sinking to the bottom of the chest cavity, owing to its weight. It is observed that these causes very largely increase the amplitude of the space occupied in the chest by the heart during the erect posture as compared to the conditions in the recumbent posture under the normal conditions of perfect health of the body.

P. C. Franze of Bad Nauheim[4] in studying the influence of posture on the normal cardiac area found by applying the orthodiagraph to the studies of the shadows (fluoroscopic) of hearts, that "in the erect posture the shadow of the heart is narrower in width and at a lower level in the thorax. The longitudinal axis of the heart assumes a position nearer to the vertical. In the recumbent posture the reverse takes place, the heart is seen higher up in the thorax; broader in width, and lying more horizontally. Inspiration brings about analogous conditions to those present in the erect posture and expiration to those in the recumbent." These observations are confirmed by Groedel.[5] Physiologists are agreed that during the ventricular systole of the cardiac cycle the anteroposterior diameter of the heart is increased, while the apex moves downward and inward, so that the heart comes to lie more vertically; almost exactly the position which we have seen is assumed by the heart during the erect posture. The standing position, therefore, encourages and aids the position which the heart must assume during the period of the cardiac cycle (ventricular systole) which represents its maximum functional effort. The erect posture is for all of these reasons the position in which the heart does its work under the most favorable conditions. In health position is of little or no importance as far as the work of the heart is concerned, for it is working with the maximum amount of reserve force ready to be called upon not only with changes of energy involved in various portions of the cardiac cycle, but with the varying demands made upon the heart in the performance of its constant work. In disease, however, the reserve force of the heart is scarcely adequate to the calls made upon it by the varying degrees of activity of the body and the emotions, and the heart may be competent more or less only in that position of the body in which it sustains the least resistance to its activity. This, as we have seen, is the vertical or erect posture of the body. Less work, however, is required from the heart in a recumbent position of the body; the body and its muscles are at rest, the circulation of the brain is increased and maintained so that much of the advantage which the erect posture gives the heart in the performance of its work is counterbalanced by the greater demand for work made upon it during the erect posture. The body demands frequent intervals of rest even in health and the constant maintenance of the vertical posture is impossible, even in health. In disease, however, with an incompetent heart under stress every aid to cardiac activity is instinctively brought into play under the limitations imposed by the diseased body, and we find that the patient has a tendency to assume a combination of the erect and recumbent posture, namely, a sitting or more or less reclining position. These principles can be applied effectively as aids in the diagnosis and differentiation of the various murmurs heard in patients suffering from organic valvular cardiac lesions. Thus the knowledge that the heart comes to lie more vertically in the erect posture and tends to lie more horizontally in the recumbent posture (Franze) involves the conclusion that the passage of the blood through the valves is favored by gravity in the erect posture in mitral stenosis and aortic regurgitation and that the murmurs heard with these lesions will be louder when heard with the patient erect or sitting; for the blood current synchronous with these murmurs is downward at these valves. Thus also, in the recumbent position, mitral regurgitation and aortic stenosis will be better heard than in the erect or semi-erect posture because the former favors the direction of the current of blood synchronous with these murmurs. Gordon,[3] to whose admirable paper I am much indebted, calls attention to the fact that gravity (erect posture) should increase the force of the flow in mitral stenosis and aortic regurgitation, and in the same posture should diminish the force of the flow in mitral and tricuspid regurgitation, aortic stenosis and pulmonary stenosis. The murmurs accompanying the two former conditions will be best heard in the erect posture and murmurs characteristic of the four latter conditions will be best heard in the recumbent posture.

Rudolf,[6] in an article confirming much of Gordon's work, claims that the force of gravity is an important factor in the relative loudness with which murmurs are heard in the erect as compared with recumbent postures. While in my experience

these facts are true of organic murmurs, it is also true that anemia murmurs at the same valves, indeed all anemia murmurs are heard best in the recumbent posture, except those over the pulmonary valve and the venous hum which are best heard in the standing or sitting position when the pulse is accelerated.

It will be readily understood that the utilization of the aid of posture in the treatment of valvular cardiac affections can be based upon the effect of gravity in increasing or diminishing the force of the flow through the valves in the pathological direction. In other words, posture can only be an aid in the treatment of cardiac valvular disease when it is such as to increase the force of the flow in stenosis and diminish the force of the flow in regurgitations, *e.g.* in mitral and tricuspid regurgitations the erect and semi-reclining posture, if the former be impracticable, will aid the heart in its work and minimize the force of the flow of blood in the pathological direction. The same posture, increasing the flow in mitral stenosis, will also be of aid. In aortic stenosis the recumbent posture, encouraging the flow of blood in the normal direction which the pathological process tends to diminish, will give aid to the heart and increase the flow in the normal direction. The relation of the aortic opening to the level of the left ventrical is such that neither recumbent nor semi-erect posture has much if any influence either in increasing or diminishing the force of the flow of blood in aortic regurgitations in the pathological direction. Unfortunately a considerable proportion of cardiac valvular disease affects not single but several valves either primarily or secondarily, or an even larger proportion have one valve affected with obstruction and regurgitation at one and the same time, enforcing stenosis and incompetence on the valve. In these cases I have found that that posture which diminishes the force of the flow in the regurgitation direction disregarding the stenosis element of the lesion will be of therapeutic value and most comfortable for the patient. This in the vast majority of cases is the erect or semi-recumbent posture, mitral regurgitation being much benefited by it and aortic regurgitation *per se* not affected by it and its complications in most cases much benefited by it.

Myocardial changes of the heart muscle either primary, as in cardiosclerosis or secondary to valvular disease very frequently terminate in marked dilatation of the heart. This, in turn, produces finally the evidences of heart failure (Mackenzie), such as edema and dropsy, enlargement of the liver, pulmonary edema and urinary symptoms due to kidney involvement. So important is this condition of cardiac dilatation in the course of various heart lesions that Mackenzie says "I doubt if we ever get the characteristic urinary symptoms of heart failure in the absence of dilatation of the heart." Pulmonary edema is undoubtedly one of the effects of dilatation of the right heart. In these cases the symptoms and physical signs of dilatation accompany those of myocardial weakness and heart failure. Any postural procedure that will make more room for the dilated heart will enable its weakened muscular wall to work under better advantage. Were the erect posture feasible in these frightfully sick patients it would undoubtedly be the

Fig. 1.—Patient in reversed Trendelenburg position, the head of the bed being raised on wooden pyramids.

position of preference, for in the erect posture, as we have seen, the chest space occupied by the heart is increased by one-sixth of its extent, while the effect of gravity upon the enlarged liver and other abdominal organs further increases this space and, what is more important, diminishes the pressure upon the diaphragm. The sitting position has a similar effect to a lesser extent for the reason that, although the chest space is amplified as in standing yet the patient does not obtain the benefit of the diminished pressure against the diaphragm; for, owing to the flexing of the body upon the hips, the pressure against the diaphragm by the liver and abdominal organs is certainly not diminished even if it is granted that it is not increased. It is for such cases as these of extreme cardiac failure due to dilatation secondary to severe valvular disease or myocardial disease that I have found that a posture which is a combination of recumbency with vertical or semi-vertical position, forms a powerful adjuvant in the treatment. These patients cannot sit up either in bed or on a chair, for even in the former case in addition to the physical weakness the position encourages cerebral anemia; yet the dyspnea, cyanosis, and orthopnea preclude the recumbent posture in bed, even when the shoulders and head are raised by pillows. Frequently the more pillows and more acute the bend at the shoulders and neck, the greater the dyspnea. Auscultatory signs of a more or less localized or general pulmonary edema are present and increasing. The patient is restless and

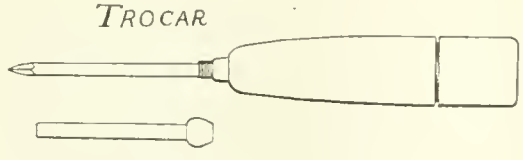

FIG. 2.—Southey tubes.

throws himself about, seeking some posture that is bearable. Following the indications above laid down, I have placed such patients in bed with the head of the bed raised as in the Fowler position, but with the patient in what I prefer to call the reversed Trendelenburg position. The Fowler position includes flexion at the knees with the pelvis forming the point of a V, the sides of which are formed by the legs and body. My patients lie on an inclined plane, body and legs extended, with the head and shoulders at the top and the feet at the bottom of the inclined plane.

When it is remembered that the object of this position in such cardiac cases is, first to remove the pressure on the diaphragm by the action of gravity on the liver and other abdominal organs, and, second, to give the patient the benefit of the increased space in the chest which results from the upright, or to a lesser extent even from the semi-upright, position, the posterior segment of the ribs being thus relieved of the weight of the body, and that further the dilated heart under these conditions is working subject to less restriction and in space more adequate to its increased size, it will be understood why these patients very soon become accustomed to this novel position of the bed, in which they seem to be more comfortable, breathe more easily, and soon remain fairly quiet and cease to throw themselves about. A patient to whom the aid of this position has been given early in the development of an attack of heart failure, and who has experienced its relief, refuses to be replaced in the ordinary bed until the dyspnea has been thoroughly relieved. There are several points which are to be accentuated in the application of this simple procedure. The posterior legs of the bed upon which the patient lies are raised 4 to 24 inches from the floor, resting upon chairs or wooden supports with a broad base and narrower top, shaped like truncated cones or pyramids, or by any other means that may occur to the physician or some ingenious relative. The full height of 24 inches should not be attained, however, at one stroke, but gradually, so that the patient may not get an annoying sense of insecurity from the unaccustomed attitude of lying on an inclined plane, down hill as it were. At the foot of the bed the patient's feet should rest against a well bolstered or padded wooden rest, which extends across the width of the bed. Well padded boards 15 to 18 inches wide should bound the sides of the bed to prevent the patient's slipping out during sleep. The whole structure should be as firm as though the patient's bed were resting in the usual horizontal manner upon the floor to give the sense of security. The patient's head and shoulders should be supported by pillows and sometimes by a bed head rest, which at Mount Sinai Hospital is made with ratchets, the teeth of which fit into the bars at the head of the bed, so that the patient's head and shoulders may be supported at any angle that is comfortable. The body should lie recumbent upon the bed in this inclined plane without any bend at the hips, so that the maximum downward effect of gravity upon the liver and abdominal organs may be obtained. The upward pressure upon the diaphragm is thus removed, the heart relieved by the increased space thus obtained, and the venous return in the portal veins, vena cava, and pulmonary veins encouraged. A bend at the hips of the patient renders negative the advantages obtained from this position of elevating the head of the bed. (See Fig. 1.)

As I have stated, I have seen patients suffering from cardiac failure as a result of dilatation complicating valvular disease and myocarditis, more especially when mitral regurgitation is an element of the valvular disease, immensely relieved of their dyspnea by this posture alone even before other more direct therapeutic measures were applied.

In many patients suffering from edema and dropsical effusions due to cardiac failure, with or without a complicating nephritis, the effusion into the serous cavities and subcutaneous edema are sometimes so general as to greatly embarrass the circulation and such important functions as those of respiration, and yet such effusions may be insufficient in quantity in one site or cavity of the body to permit of their removal by paracentesis or puncture; again the subcutaneous edema may be very extensive all over the body and yet not sufficient in quantity in any part of the subcutaneous area to admit of drainage by Southey tubes. In both of these classes of cases the reversed Trendelenburg or modified Fowler, above described, has been of the greatest value to the patient. Placing the patient in bed in this inclined plane posture for 24 to 48 hours has permitted the subcutaneous serous effusions to accumulate in the legs, compelled by the force of gravity, whence it was readily drained by two or more Southey tubes put into each of the lower extremities. I have records of such patients thus draining off remarkable amounts of fluid from Southey tubes thus applied in the recumbent "down hill posture," e.g. R. H., a patient admitted to Dr. Alfred Meyer's service in

the summer of 1909 with cardiac incompetence and dropsy drained off through Southey tubes 12,000 c.c. in 48 hours. Not only is the subcutaneous edematous effusion drained off, but patients who have with the edema dropsical effusions into the peritoneal and pleural cavities, insufficient in amount for paracentesis or aspiration absorb these effusions from such cavities as the subcutaneous edema, drained off by means of the Southey tubes in the inclined posture of the patients, subsides. Before making use of this posture I found Southey tubes of only doubtful efficiency in the draining away of subcutaneous edema; only small quantities of fluid were drained away in patients lying in the ordinary bed in the recumbent posture; this was the case in the first patient above cited. It was for this reason that I requested the house physician to place the patient in the reversed Trendelenburg position, and was pleased to find that the fluid was drained off to the extent above indicated so that the bottles at the foot of the bed had to be frequently emptied. A similar case occurring last summer in the same service drained 18,000 c.c. in two days. Water runs down hill by gravity when located subcutaneously in the living body just as surely as it does in a water shed when located under the surface of the ground.

Although I have here referred to the use of this downward and inclined posture to aid drainage of edemas occurring in cardiac cases through the Southey tubes applied to the legs, exactly similar and effective use can be made of the same posture in the drainage of similar effusions as a result of idiopathic or complicating nephritic lesions and cirrhosis of the liver. Indeed, in all cases where the Southey tubes are applied they should be applied at the lower extremities of the inclined plane represented by the bed, upon which the patient lies, the head of the patient being at the upper extremity of the incline. In this way the practical value and utility of the Southey tubes is many fold increased. Such drainage under such circumstances is rapid, effective, and thorough, and the rapidity of the drainage does away with the chief objection to the Southey tubes, namely, that the points of puncture become sources of irritation and infection, not rarely complicated, in their customary ineffectual use by erysipelas. The rapidity and force of the drainage current in the inclined plain, as described, obviates irritation because for the short period of two or three days the cutaneous surface around the tubes is readily protected and before the dermatitis has had time to develop the drainage has been completed, the tubes removed and the patient's bed returned to the horizontal position. Dry gauze dressings are then applied with bandages, and the skin of the legs protected against infection. The openings made by the tubes then rapidly close.

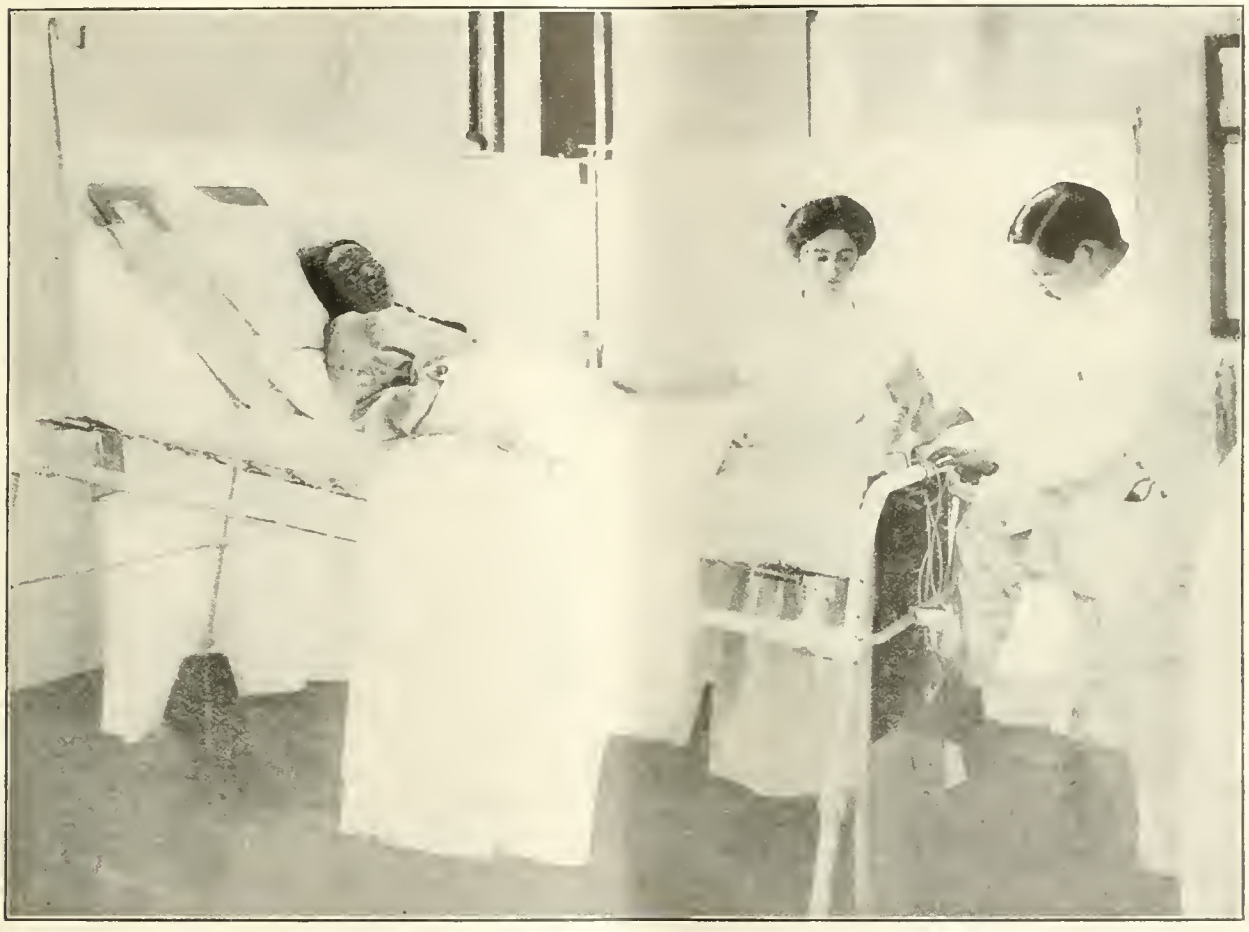

Fig. 3.—Patient in reversed Trendelenburg position on inclined plane to encourage flow through the Southey tubes applied to the feet and legs, with fine tubes draining from the Southey cannulæ into a bottle at the foot of the bed.

It has been the object of this paper to call attention to the aid that is given by various postures in the accurate recognition and treatment of medical conditions. I have been especially desirous, however, to show that in the diagnosis and treatment of cardiac affections the use of posture rests upon sound dynamic and physiological principles. I have attempted to indicate some of these principles, and I have called especial attention to the powerful aid

given by the reversed Trendelenburg position in the use of Southey tubes in the draining away of serous dropsical effusions, complicating cardiac and nephritic lesions.

THE CHEMOTHERAPY OF EHRLICH, WITH SPECIAL REFERENCE TO THE TRYPANOSOME INFECTIONS.*

By B. T. TERRY, M.D.,

NEW YORK.

(From the Laboratories of the Rockefeller Institute for Medical Research.)

In his search for medicaments that might cure the trypanosome infections, Ehrlich[1] has reached two important conclusions. The first is that all chemicals which exert a curative effect on these infections are poisons. That is, they are capable, when given in sufficient quantity, of harming the vital organs of the host. In estimating the value of medicaments it is necessary, therefore, to compare the effect they have on the parasites with that they exert on the organs. The affinity the medicaments have for the parasites is termed *parasitropism;* that they have for the organs, *organotropism.*

For a medicament to have a practical value the proper relation should exist between the *organotropism* and the *parasitropism.* The *parasitropism* must be as strong as possible, and the *organotropism* as weak as possible. Under these conditions we may rid the body of the infecting parasites with the minimum of harm to the host.

Fixation.—The second conception is simple, and to Ehrlich almost self-evident. It is that a parasite cannot be poisoned by a substance unless that substance can be attached or fixed to the parasite. For example, if arsenic is to injure the trypanosomes, there must be some means by which the arsenic may be attached. Should this mechanism not be present the trypanosomes could be suspended in the poisonous solution without being harmed. We shall soon see that there are solutions of arsenic in which the trypanosomes may be kept for some time without apparent harm, and others which destroy the parasites very quickly. According to Ehrlich, the difference in the action in these two cases is due to the fact that the trypanosomes have no mechanism for fixing the first solution, but have one for the second.

As a result of experiments that cannot be given here, Ehrlich believes that the fixation of various chemicals by the trypanosomes is brought about by the presence of definite chemoreceptors in the protoplasm of the parasites. These chemoreceptors have affinities for certain medicaments, and by means of these chemoreceptors the medicaments are attached to the trypanosomes.

*Read before the Medical Society of the County of New York, February 27, 1911.

This theory has been so productive in Ehrlich's hands that we will now apply it to results that may be obtained in the laboratory.

There are, in general, two methods of testing the value of medicaments to be employed in the treatment of trypanosome infections. The first, or *in vitro* method, is to mix the medicament directly with the trypanosomes and observe the effect upon their morphology and motility. In these experiments one must remain within certain limits of concentration, for our conception of poison is relative, and innocent substances, such as sodium chloride, have a destructive and killing action on living tissues if the concentration is sufficiently great. In the second, or *in vivo* method, the curative value of the medicament is tested by injecting it into an infected animal and observing the result. In order to detect a slight action that the medicament may exercise it is necessary in these tests to inject the largest non-toxic doses.

The results of these two methods of testing medicaments may or may not agree. There are four possibilities, which we shall represent as follows: O O, + +, + O, and O +.

The first possibility, or O O, is that the medicament has no action either *in vitro* or *in vivo.* This is interpreted as meaning that the parasites have no chemoreceptors for the medicament employed, or else that the substance is not a poison.

The second possibility, or + +, is that both *in vitro* and *in vivo* the medicament has a positive action on the parasites. In this case we have evidence that the mechanism for binding the medicament is present in the parasites.

The third possibility, or + O, is that the medicament *in vitro* may be active, but *in vivo* fail to influence the course of the infection. One of the most striking examples of this was found by Hata in Ehrlich's laboratory. In testing various substances upon different parasites Hata was struck by the extremely toxic action methylene blue exerted upon the spirochætæ of relapsing fever, for this substance killed the spirochætæ even in a dilution of 1 to 6,000,000. In spite of this remarkable activity the substance *in vivo* was a complete failure. Even when the dose employed was more than 500 times as large as would have been necessary to kill all of the organisms if the entire mouse had consisted of nothing but spirochætæ, the curative injection into an infected mouse did not have the slightest favorable effect. This means, according to Ehrlich's theory, that the spirochætæ have chemoreceptors for the methylene blue, but that the presence of these is rendered useless by the unfavorable relation which exists between the organotropism and the parasitropism. In this particular case the organotropism is more than 500 times as strong as the parasitropism.

The fourth and last possibility, or O +, is that the medicament *in vitro* exerts no apparent effect, but *in vivo* is found to have a curative action. This is the so-called indirect, or paradoxical action, and atoxyl is a well-known example. Atoxyl in weak or strong solution exerts *in vitro* a negligible action on trypanosomes, while *in vivo,* even in dilute solution, it is highly parasiticidal. In order to explain this we may assume that the trypanosomes have no chemoreceptors for atoxyl, but that the medicament, after injection into the animal body, is converted into another for which the parasites have chemoreceptors. The possibility of this conversion occurred to Ehrlich, for he knew, from other work,

that the tissues of the body exert a reducing influence. In testing his theory Ehrlich reduced atoxyl in the chemical laboratory and obtained paramidophenylarsenoxyd. Solutions of this substance he then mixed *in vitro* with trypanosomes, and found that it immobilized these parasites in less than an hour, even when the substance was diluted one million times. Ehrlich believes that the substance produced in the animal body after the introduction of atoxyl is paramidophenylarsenoxyd.

The chemical explanation for the difference in action *in vitro* of atoxyl and paramidophenylarsenoxyd lies in the fact that in atoxyl the arsenic rest is pentavalent, and has, therefore, no additional affinities. In paramidophenylarsenoxyd, on the other hand, the arsenic molecule is unsaturated and has a valency of three. This latter substance, therefore, possesses additional affinities, by the aid of which it is in a position to combine chemically. In other words, the arsenic receptor of the trypanosomes is adapted, not to pentavalent but to trivalent arsenic.

There is another class of substances which show the paradoxical action. If a certain pyronin is mixed *in vitro* with trypanosomes in a dilution of 1 to 20,000 or 1 to 60,000, it has, according to Ehrlich, no apparent action on the parasites. Nevertheless, if the mixture of the medicament and actively motile parasites is injected into a susceptible animal no infection takes place. In this case Ehrlich offers an entirely different explanation. In spite of the apparent lack of action, he assumes that the parasites have chemoreceptors for pyronin, and that the medicament is therefore bound to the parasites. The lack of effect *in vitro* is explained as being due to the fact that the medicament is fixed to some part of the parasite which does not influence motility or morphology. This part Ehrlich considers to be the one governing reproduction. The injected parasites have, therefore, been injured in spite of their normal appearance, and the injury consists in a sterilization. No infection followed the introduction of the parasites, for the reason that the trypanosomes were no longer able to reproduce their kind, and quickly died out after being injected.

In support of the view just given Ehrlich cites the results of Busk, who found that certain ciliates, paramecium for example, could live for weeks in a strong solution of trypanred. Busk observed, however, that the parasites did not increase in number, and found that the sterilized action of trpanred was exerted even in very dilute solutions.

According to Ehrlich, this conception may have a very practical application. If the therapeutic dose of a sterilizing medicament is very much less than that of another which destroys the whole organism it will be possible to use very much smaller quantities of the former, and yet obtain the effect of the latter, for in an infected animal, the sterilization of all of the parasites is equivalent to killing all the organisms, when the life of the individual parasites is measured by a few hours or days. The smallness of the dose is important for the reason that all medicaments that are parasiticidal are, according to Ehrlich, poisons, and the less we have to give the greater the chance of treating without doing harm to the host.

We have thus far considered normal trypanosomes. Let us now apply Ehrlich's chemoreceptor theory to abnormal, or resistant trypanosomes, for in Ehrlich's laboratory it was found that trypanosomes could be rendered resistant to treatment, and strains of this kind have now been produced against representatives of each group of the medicaments known to be active against trypanosomes.

Resistant strains differ from the normal in that it takes more medicament *in vitro* to kill them, and, when the resistance is high, it becomes impossible to destroy the parasites in the animal body by injecting the medicament against which the resistance has been acquired. According to Ehrlich's theory, the chemoreceptors of the trypanosomes that acquire a resistance to medication have suffered a loss of avidity for the medicament that they normally bind.

This loss of avidity of the chemoreceptors is a purely chemical conception. In the parasites there is no morphological change corresponding to it. Moreover, the loss is relative, not absolute. The diminution in the avidity is merely to the extent that the resistant trypanosomes are unable to take up the medicament in the concentration in which it is present in the body fluids of the species of animal in which the resistance was developed.

Curing Resistant Strains.—As Ehrlich had shown that resistant strains could be made in the laboratory, it was important to find some means of curing these strains, as it was quite possible that resistance might be produced unintentionally in the treatment of trypanosome infections. He therefore set himself the problem of curing animals infected with trypanosomes rendered resistant to atoxyl, and, after a number of months, found a medicament that could do this. This was arsenophenylglycin.

Ehrlich then attempted to produce a resistance to arsenophenylglycin, and again, after a certain number of months, succeeded in securing trypanosomes that could no longer be cured by this medicament.

In attempting to explain the resistance of trypanosomes to arsenophenylglycin, Ehrlich first assumed that the affinity of the arsenic receptor of the trypanosomes had undergone a further reduction. This conception, however, he soon discovered was incorrect, for, on testing *in vitro* the trypanosomes resistant to atoxyl and those resistant to arsenophenylglycin he found that it took just as much paramidophenylarsenoxyd to kill one as it did to kill the other. From this it was evident that the chemoreceptors for arsenic had not been altered.

Another explanation was, therefore, necessary, and this was soon forthcoming, for Ehrlich found a number of medicaments (derivatives of phenylarsenic acid) which, like arsenophenylglycin, could cure animals infected with the atoxyl resistant strain. He noted, moreover, that all of these medicaments were alike in one respect—they all contained the radical of acetic acid, CH_2CO_2H. He drew the conclusion, therefore, that arsenophenylglycin had acted by means of its acetyl group, and that when the strain resistant to arsenophenylglycin was produced the acetyl receptor had suffered a diminution in its avidity for the corresponding group in the medicament.

From this it would appear that trypanosomes have at least two chemoreceptors by which arsenophenylglycin may be fixed—the *acetyl* and the *arsenic* receptors. According to Ehrlich, both are active in binding the medicament. Believing that the acetyl receptor is the first to come into play, he calls this the *primary haptophore*, and the arsenic receptor the *secondary haptophore*. This process by which a medicament is bound, first by one receptor, and then by another, Ehrlich has likened to the pin-

ning out of a butterfly, in which the first pin fixes the body, the next one wing, the next the other wing, and so on.

Aiming.—Ehrlich regards it as highly important to learn the chemoreceptors possessed by the parasites, because this knowledge can then be used to enable one to *aim* directly at the parasites we wish to destroy. For if we know all the chemoreceptors a parasite has, we can then attach corresponding side chains to some of our active radicals, *e.g.* Hg., As., or I. In this way we may force the poisonous substances on the parasites, and with deadly effect. An example will help to make this clear.

In testing various medicaments Ehrlich employed in one instance a substance that had an action on both trypanosomes and spirochætæ. He wished to increase the activity of this medicament for the spirochætæ. As iodine has a decided curative effect on syphilis, he concluded that certain spirochætæ must have iodine receptors. He therefore introduced iodine into the medicament and then tested it once more. The result showed that its destructive action for the spirochætæ had increased greatly

The problem is, however, not at all a simple one. Although the introduction of iodine increased the value of the medicament for spirochætæ it did not leave unchanged its effectiveness against the trypanosomes, since on testing it on these organisms its activity was found to have greatly decreased. This is to be explained, according to Ehrlich, by assuming that the introduction of iodine so altered the relation of the arsenic group that the chemoreceptor for this group could not act as freely as usual. In support of this conception Ehrlich cites an example in which two chemicals unite ordinarily only at a high temperature. The introduction of a side chain into one of these chemicals so altered its relation to the other that they could combine at room temperature. The introduction of a second side chain, however, made the reaction as difficult as in the beginning, and the addition of another side chain made the union still more difficult.

Steps in Chemotherapy.—We may now give briefly the steps by which medicaments are found and improved. First of all, it is necessary to secure substances which have some action on the parasites we are trying to destroy. The attempt is then made to determine the active groups in the medicament, and when these are known, or even before, one begins to make chemical variations in the substance with the hope of increasing its parasitropism and decreasing its organotropism. This means that we must select from our stock of chemical variations the ones which are best for therapeutic use.

Best Medicaments.—In the selection of the best medicaments several points must be borne in mind.

(1) The medicament should be *safe*. The curative dose must bear the proper relation to the lethal dose. If the former is eight or nine-tenths of the latter the medicament is too dangerous to use, unless the case is desperate and nothing better is at hand. Moreover, the medicament should not easily give rise either to resistant strains among the parasites or to hypersensitiveness in the patients.

(2) The medicament should be *efficient*. It should cure the largest possible number of species of trypanosomes, and also the largest possible number of hosts infected with these strains. It is highly desirable, furthermore, that it should be able to cure the resistant strains that are apt to have been produced by previous treatment.

(3) The medicament should be one that it is *convenient to use*. It should be easily administered, give rise to little pain, and be followed by no disagreeable or serious consequences, such as ulcers, necrosis of the skin, loss of hearing, or blindness; and

(4) The action should be *rapid* and *sure*.

When the best medicament for the treatment of laboratory animals has been found it becomes necessary to introduce it into practice. In the case of human therapy this is very difficult, for it is not possible quickly and easily to ascertain how much of the drug a man can stand. We must begin with very small doses and gradually increase these as we find it is safe to do so. In this way we can eventually determine the maximum tolerated dose.

As a model of the way a medicament should be introduced into practice, we may take the 606 of Ehrlich and Hata. At first this medicament was entrusted only to hospitals and skilled workers, and was given free to these with the request that, in the beginning, only cases of a certain kind be treated, that careful records of the results be kept, and that these should be communicated promptly to Ehrlich. In this way the instructions which accompanied each supply of medicament that left the laboratory could be based upon the latest experimental results, and the dose could be raised as rapidly as was safe. Some twenty to thirty thousand patients were thus treated before the medicament was placed upon the market.

We may now summarize the points of most importance in introducing a medicament into human therapy. (1) *Uncomplicated* cases should be selected, in order that the action upon the disease studied may be ascertained without being obscured by the effect the drug may exercise upon some one or more of the complications. (2) *The cases chosen should not previously have been treated*, for experience has shown that the administration of one medicament may render the host hypersensitive to the influence of another. For example, it has been found that atoxyl treatment renders the host hypersensitive to acetyl-atoxyl. When sleeping sickness patients received acetyl-atoxyl after they had been treated with atoxyl, alarming symptoms appeared—symptoms that were not seen at all, or but rarely, in the treatment of patients that had not previously received atoxyl. (3) The cases selected for treatment should be *early* ones, since experience teaches us that the later stages are much more difficult to treat. If a medicament should be judged merely by its effect upon the later stages many useful remedies would be discarded, and the opportunity of using these as a base from which to work for more effective substances would be lost.

Best Conditions.—After selecting the right patients, these should be put under the best possible conditions for observation and treatment. (1) They should be put to bed, if possible, several days before the beginning of treatment, in order that the effect of rest upon the disease may not be attributed to the medicament. (2) The diet and bowels should be regulated, and the pulse, temperature, and respiration kept under observation, and (3) Prolonged, careful records of the cases should be kept, in order that data may be at hand for determining the following points: The indications and contraindications for treatment, the dose, and the proper method of administering the drug.

The Treatment.—In general, there are two methods used in the treatment of trypanosome infections—the intermittent and the energetic. In the inter-

mittent form a dose which is insufficient to cure the animal is administered repeatedly with intervals of a number of days between. The hope is entertained that the repetition of the small doses at these rather considerable intervals may eventually cure the animal. In the treatment of rabbits this method has given good results, but with other animals the effect has been less favorable, and in many cases bad.

By the second, or energetic method, only one treatment is given. This may consist of a single injection of the medicament, or of two large injections within forty-eight hours. When these are given the treatment is stopped, and is not again repeated if bad symptoms do not return.

Avoid the Intermittent.—In the treatment of sleeping sickness with arsenophenylglycin Ehrlich thinks that the intermittent form of treatment should be abandoned. He gives three reasons.[2]

(1) It is *ineffectual.* A given small dose of medicament which fails to rid the body of the parasites when first introduced is no more able to do this when repeated a number of days later.

(2) The intermittent method may lead to *hypersensitiveness* on the part of the patient, and this is doubly dangerous, since the symptoms that follow hypersensitiveness make it impracticable to increase the quantity of the medicament given, and the original dose becomes less and less effective as the tissues of the hypersensitive host bind more and more of the drug.

(3) This is the method by which *resistant strains* are produced, and resistant strains constitute one of the most serious dangers in the treatment of trypanosome infections, for they make the cure of the patient exceedingly difficult, if not impossible.

Three Groups of Medicaments.—As the result of testing perhaps thousands of preparations we have at the present time three groups of medicaments that are active against trypanosome infections. These are as follows:

(1) The arsenic and antimony group. The most important arsenic preparations are arsenious acid, atoxyl, acetyl-atoxyl, arsenophenylglycin, and, last of all, 606. Of the antimony compounds we may mention the antimonyl tartrates of potassium and sodium, aniline antimonyl tartrate, and the antimonythioglycollic acid compounds.

(2) The group of azo dyes. Examples are trypanred, trypanblue, and trypanviolet.

(3) The group of basic triphenylmethane dyes. Here we may mention parafuchsin, pyronin, and tryparosan.

Of the medicaments thus far tested the one which has given the best results in the largest number of trypanosome infections in the largest number of hosts is arsenophenylglycin. In the treatment of mice, rats, and rabbits a single dose suffices to cure. The medicament has also been of considerable value in the treatment of larger animals and of man. But its use has shown that the trypanosomes in various parts of the world react in a most variable manner. According to the way the parasites respond to treatment, Erlich divides them into three classes.

(1) The favorable case, or "*casus faustus.*" Here a single dose suffices to cure, and the dose employed is only one-half or one-third of the highest tolerated dose. In the laboratory many examples of this have been met with. Ehrlich cites here the results of Strong, who, with a single injection that was only about one-half of the lethal dose, cured 90 per cent. of the monkeys (*Cynomolgus philippinensis*) infected with surra.

(2) The doubtful case, or "*casus dubius.* The medicament may cure, but the necessary dose is close to the toxic one. Medicaments which give this result may still be used to advantage in the treatment of animals that are sure to die unless treated. As an example, Ehrlich refers to the results of Strong, who found that arsenophenylglycin could save one-third to one-fifth of the horses naturally infected in the Philippines. Strong recommends, therefore, the use of arsenophenylglycin in the treatment of all valuable horses infected with surra.

(3) The unfavorable case, or "*casus infaustus.*" The resistance to treatment is so great that the medicament fails altogether to cure.

The first thing to find out in practical therapy is in which of the three categories the case to be treated falls, and then to adopt the proper measures. In case two, for example, combination treatment should be resorted to. Broden is now using tryparosan in combination with arsenophenylglycin with excellent results, where arsenophenylglycin alone had proved unsatisfactory.

In Uganda, also, arsenophenylglycin has proved far from satisfactory in the treatment of sleeping sickness. The fact that many of the cases treated were very advanced may partially explain the result, but it seems practically certain that the parasites there have an unusual resistance to arsenic.

As a contrast to the result in Uganda, the experience of von Raven in Togoland should be referred to, for the sleeping sickness organisms there seem to be as easy to treat as in Uganda they are difficult. "Of twenty-three patients * * * who received two days running from 0.7 gm. to 1.2 gm. arsenophenylglycin, all were well twelve months later."[3]

District Treatment.—As a consequence of the remarkable variations toward the curative action of a given drug shown by trypanosomes in different regions, Ehrlich suggests that it may be necessary to adopt a form of *district treatment.* This may mean that parasites will be obtained from the regions where the usual forms of treatment are unsuccessful, taken to the laboratory, and there studied with the purpose of securing a form of treatment that shall be adapted to the infections in these particular regions.

Whether this be necessary or not will probably depend upon the results obtained with newer medicaments, for it is always possible that some may be found which will have a wider applicability than any yet tested.

606.—The only other medicament that we shall mention is 606. This has proved to be of value, not only in the treatment of spirochetal infections, but also in those caused by the trypanosomes. After satisfactory results had been obtained in animal experiments, Ehrlich sent some of the medicament to Broden in Africa, and the latter found that an injection of 0.3 to 0.6 gm. of 606 caused the parasites to disappear promptly from his patients. The time, however, is too short for us to be able to form a judgment concerning the permanency of the result.

While it is quite possible that the best medicaments for the treatment of the trypanosomiases have not yet been found, the situation is not at all discouraging, for the way to secure active curative agents is now known with exactness. If the medicaments in our possession prove inadequate, we have but to continue our search until the right ones are found.

DEATH RATES IN THE JAPANESE WAR.

By CHARLES E. WOODRUFF,

LIEUTENANT-COLONEL, MEDICAL CORPS, U. S. ARMY.

Analysis of the Japanese deaths from disease and bullets in their late war has been hitherto based upon surmises, for little definite information has ever been divulged as to how many soldiers were in the field. From a reliable source it has recently been learned that they have at last given out statistics which permit a more accurate comparison with other wars. The following are the latest official figures:

Killed and died of wounds	60,542
Died of disease	26,581
Total	87,123
The following had formerly been reported:	
Killed	47,387
Died of wounds	11,500
Total	58,887
Died of disease	21,788
Total	80,675

Others had stated that about 29,000 had died of disease, with a total of about 86,000 deaths.

There were 938,996 under arms during the entire war, with an average strength of 350,000. At the end of hostilities 375,218 were at the front and 213,615 with the lines of communication and bases, a total of 588,833. It has previously been assumed that they had 1,200,000 under arms and that "nearly 800,000 were with the colors at its close," and even that they had an average strength of 800,000. From 1861 to 1865 we had about 2,000,000 different men under arms and much more than 2,500,000 enlistments, counting soldiers who re-enlisted. Grant had over 300,000 in the vicinity of Virginia alone and the armies throughout the country totaled about 1,000,000. That is, our war strength was almost exactly double the Japanese.

They were actively engaged about 18 months and their deaths from wounds amounted to 3,364 per month, or, relatively, 3.16 times our monthly battle losses in the 48 months of the Civil War, when we had 2,128 per month, or a total of 102,030, including a third of the 24,184 who died of unknown causes. This shows how fierce the fighting in Manchuria really was. It had been previously reported also that they had 47,387 killed outright in their 18 months, while in the whole Civil War there were 44,238. The Japanese deaths from disease were 1,477 per month, which is 35 per cent. of our Civil War rate of 4,215, or a total of 202,339, including two-thirds of the 24,184 deaths from unknown causes. Considering the fact that they campaigned in a northern climate to which they were suited, and where disease is not a strong factor in the sparse population, while we fought in the South where the summer climate is enervating to Northerners, and where typhoid, malaria, dysentery, hook-worm, and other infections were very prevalent in a dense population, as at present; and considering also that long wars are notoriously sickly, the Japanese results are bad.

Furthermore, there was no science of sanitation in 1865. It is quite evident, therefore, that they found it impracticable to apply modern sanitation at the front, or if they attempted it infections are unavoidable in such unnatural conditions of living. We really do not know what they did at the very front, for no foreign observers were permitted there. A great deal of nonsense has been written about their superhuman success in preventing sickness, but as a matter of fact they had an unknown but enormous amount of beriberi, which is their special *bete noir*, like typhoid to us. Beriberi has been reported as one-fourth of all the sickness and some estimate that 16 per cent. of the soldiers had it. Moreover, though it was formerly reported that there were "only" 236,223 "sick" admitted to hospital, the present official figures are 479,842 for all causes, or more than half the total strength, which indicates much illness, even making liberal deductions for the unknown number of wounded, formerly said to be 173,425.

We have no means of comparing these figures with our own, for one Japanese surgeon-general reported that their records do not include soldiers treated with the troops, but only those sick enough to be sent to the fixed hospitals. Our statistics are of the "sick report," not hospital cases, and include every soldier excused from any part of his military duty, even for a sprained wrist which prevents drill for one day, and the vast majority of the "hospital" cases are trivial. As it is very difficult for a soldier to pass a year without several minor illnesses or accidents, preventing duty a few hours, our yearly sick report is always more than the total strength even in garrison, and in war, of course, it is more. Every man may be two or three times on sick report in the year without indicating serious illness. But it is fair to presume that the serious cases were about the same proportion in both wars. Some years ago the Japanese reported 27,158 "infectious" cases, whatever that means. It has been stated that in our Spanish War up to September, 1898, we had 22,000 more hospital admissions than the Japanese army of 1,200,000 in their campaign of nearly two years, all of which is now seen to be grossly erroneous. With an average strength of 250,000 we had about 258,000 sick of all grades in four months, but they, with an average strength of 350,000, had nearly half a million serious "hospital" cases in 18 months.

In the Franco-Prussian War the Germans lost 3.37 per cent. by battle and 1.86 per cent. by disease, but the Japanese lost 6.5 per cent. by battle injuries and 2.8 per cent. by disease, and in the long Civil War we lost 5.5 per cent. by injury and 10.1 per cent. by disease. In the Spanish War, with 275,717 soldiers, 293, or one-tenth of 1 per cent., were killed, and 2,565, or nine-tenths of 1 per cent., died of disease, and even if we include later deaths which could be laid to the war there were only 1.3 per cent. or 3,681. We do not know whether the Japanese 2.8 per cent. includes these later deaths or only those dying during actual hostilities. In the whole year 1898 we lost 2.69 per cent.

The diminution of the proportion of deaths from disease to those from injury in the Japanese Army may thus be due to increase of deaths by bullets or decrease of deaths by disease. The latter has been assumed to be the case, though as an actual fact these latest returns show that the former is the only reason. For instance, considering the battle losses the same in the Civil and Japanese

Wars, for every 100 killed we had 200 die of disease, but they had only 43, two-ninths of our rate; but considering the disease deaths the same in each case, for every 100 such we lost 50 by bullets and they 228, or four and one-half times our losses. In a war with few battles the disease deaths may be many times those of battle and yet the army be far healthier than the Japanese. That is why our Spanish War cannot be compared with the Japanese, with its 21 big battles and 50 little ones. It is better to take the Civil War, where our monthly battle losses were approximately 1 per 1,000 soldiers, compared to the Japanese 3, and our disease losses 2 per 1,000, and the Japanese 1.5. In the Spanish War the troops were in camp an average of about 6 months, at a very low estimate, and it is safe to say that in that time the monthly losses were 1.5 per 1,000, or exactly the Japanese rate, and this in spite of campaigning where there were epidemics of yellow fever, dysentery and malaria.

These official figures are vastly different from the wild assertions made in the beginning of the Japanese conflict, as to their revolution of warfare by the total elimination of disease. While certain journalists and doctors have been foaming at the mouth over the losses in our Spanish War in epidemic tropical territory, they have nothing but hysterical praise for the Japanese who now acknowledge identical losses in northern healthier country, and who should have had far less, for our Boxer campaign in 1900 in similar circumstances was far less deadly. As it has been repeatedly shown that practically all our losses were due to disease, and necessarily many times the deaths from bullets, any further statements that this comparison alone indicates worse conditions than the Japanese are disingenuous misinterpretations. It has been remarked that there were "nearly 2½ Japanese battle casualties to 1 from disease," while we had "nearly 14 from disease to one from casualties," and the writer asked "was there ever before such a record of disgrace?" His figures merely show that they had 35 times as many battle losses and are in the same disgrace as to disease, if it was a disgrace, a subject we cannot discuss for some years.

The matter is now becoming even worse. Military observers have reported widespread neglect of ordinary sanitary precautions among the Japanese and such as would have wiped out troops in the tropics, as in the French Madagascar campaign, where 5,600 died of disease and only 101 were killed by the enemy, for they had bad sanitation and no battles. In some respects the Japanese results were worse than the Russian, particularly in the percentage of recoveries due to poorer hospital facilities. We must, therefore, be prepared for the final reports on both sides, which now seem destined to show that the Russian losses were less in every respect. The contrary is now so generally believed that it is doubtful whether the official figures will have the least effect in dispelling the curious delusion as to Japanese superiority.

Nothing is yet known as to the exact proportion of killed to wounded or the percentage of combatants hit, but from what is known in a general way the proportions on both sides are about the same as in other wars—one killed to four wounded—but it is believed that the Japanese had the higher percentage of both classes. Modern weapons have not altered these results of battles. The Japanese were more reckless and sacrificed men unnecessarily. The whole campaign against Port Arthur is now said to have been as unnecessary as it would have been for us to have beseiged Havana in 1898.

On account of the smaller bullet and the immediate use of aseptic first-aid dressings, the number of wounded who recover is vastly increased nowadays. There were probably about as many wounded in the Civil War as on the Japanese side in their late war, yet we lost 49,731, or about one-fourth of them, while, as far as known, the Japanese lost only 12,000 or 13,000, or about one-fifteenth of theirs. Modern surgery saves many more too, but it is now more than suspected that the Russians saved far more of their wounded than the Japanese did, and our results with the few wounded in the Spanish War were better than both.

It is thus seen how unsafe it was to praise the Japanese and condemn the Russians before we knew their results. With this record of nearly half a million serious cases crowded into numerous huge hospitals, of a force averaging only 350,000, what should we say of the statement that the Japanese "have proved, as has never done before, that preventable disease is preventable and crowded hospitals can be eliminated." As they are human, war is the same with them as it ever was with us, and ever will be, hell.

The original mistake was due to our ignorance of the wonderful Japanese ability to conceal military secrets. It was a vital necessity to hide their weakness and losses. They were numerically superior to their opponents until the very last, for it required 18 months to transport the big Russian army several thousand miles over a single-track railroad. The Russians were not strong enough to fight except defensively until the armistice, and as they were rapidly becoming stronger and the Japanese weaker, it does not require any military knowledge to predict the result if they had ever been permitted to fight it out. We would now be praising the other side, for nothing succeeds like success. The point for our present purpose is the adroit manner the Japanese hid their losses, even a battleship's sinking was not known until after the war, and allowed civilian correspondents and medical observers to "see" a part and telegraph false news to deceive the enemy. It was magnificent—and war too; it may have had much to do with ending the war when they had had enough.

The psychology of war is beautifully illustrated by the public opinion which applauded the efforts to end "the slaughter of the Russians" at the very time the Japanese were suffering the most. We were convinced that the Russians, though the numerical superiors, were being whipped by the little under dog. Our sporting instinct was aroused. Clergymen even stated that God was on the side of the weaker battalions, so we stepped in, to frustrate the Almighty. He who now thinks we could thus check the Aryans who are guiding the Russian Empire does not know the possibilities of the hordes of soldiers being garrisoned in Siberia, now that a double-track railroad is soon to be available. Public opinion is notoriously fickle and we may confidently predict a revulsion of feeling toward the outnumbered Russians who conducted a magnificent campaign. As soon as we learn the grandeur of the Russian achievements, both medically and strategically, Russophilia of our hereditary friends will soon replace the temporary Russophobia fostered by some of our citizens. The individual soldier was splendid as he always has been. He is the

most stubborn defensive fighter in the world, and for that reason his retreat before overwhelming numbers was so slow.

The total abstinence advocates have been persistently calling attention to the fact that the Japanese freedom from disease was due to abstemiousness, but Capt. L. Z. Solyviev of the 34th E. Siberian Rifles now reports that frequently the Japanese prisoners of war were taken intoxicated and more than once hanshin found in their canteens. So we must now expect a reversal of opinion and the announcement that the enormous amount of sickness was due to intemperance.

We may even expect hysterical praise of the splendid patriotism of the Russian soldiers and lack of it in the Japanese, who, it is now charged, had to be shot at by his own side to keep them from abandoning dangerous positions. Capt. Solyviev says that Russians frequently refused to go to the rear when wounded but kept on fighting, or would beg to leave the hospital before wounds were healed. "The Japanese," he says, "differs from the Russian soldier in his fanaticism, hatred of the enemy instilled into him since childhood, adroitness and skill, his fighting with rage, sending a bullet into the back of a foe who has just shown him mercy, biting when taken prisoner. This is why our men do not show mercy in attack. Our men have no hatred of the enemy and not a shadow of fanaticism. The soldier is kind to the prisoner of war and treats him gladly to tea and cigarettes. The Japanese display, not only among the men, but also among the officers, a cruelty which does not exist in the Russians.

"Eye witnesses among the Siberian officers have told men how Japanese officers shot down our wounded. The Japanese deem all means good to attain their aim, showing no mercy to their men or to ours. Firing against their own troops is evidently not an extreme measure, for it was noticed frequently. The principal difference between the Japanese officers and men and ours is shown in the means of exciting the troops to battle. The Japanese officer walks in the rear of the soldiers and drives them on with the revolver and sword, while our own officer rushes forward shouting 'Follow me, brothers; don't give me up;' and the brothers do not give him up. The Japanese like ruses—without them they are not sure. Large and small ruses are met with at every step."

One cannot judge how much truth there is in these statements, but we need not be surprised if Americans will soon believe them. We are destined for a carnival of Japanophobia as ridiculous as the Japanophilia which credited them with superhuman sanitary abilities.

Multiple Lesions of the Kidneys.—Zimnitzki describes the case of a patient in whom at autopsy there was found a right-sided hydronephrosis, caused by a calculus, and atrophy of the left kidney, with compensating hypertrophy of the right kidney.—*Annales des Maladies Genito-Urinaires.*

A CASE OF ERYTHREMIA WITH UNUSUAL FEATURES.*

By N. E. BRILL, M.D.,

NEW YORK.

The object of presenting this patient is not to show you a rare disease as much as to demonstrate in her most unusual features of the disease. The patient is a woman 60 years old, a Russian Jewess, married, and having four children. She suffered from measles and chicken pox in infancy. No member of her family had or has a large spleen. With the exception of the illnesses in her childhood she had been exceptionally free from any illness until twenty years ago, when she was troubled with "kidney disease." This kept her in bed a few weeks, she says, when she regained complete health.

Her present illness began four years ago with gradually developing attacks of headache, dizziness, and ringing in the ears. The headache was very frequent, not invariably constant, and was increased on bending down. The vertigo was associated with what she calls "fainting spells." Shortly after their beginning she noticed under the ribs on the left side a mass which slowly increased in size. These symptoms remained for two years, the mass in the left side growing steadily larger, when she sought relief at the Post Graduate Hospital, which she entered on August 14, 1908. Inquiries from that institution showed that no diagnosis was made in her case, that examinations of her blood demonstrated a marked erythrocytosis and a leucocytosis. In addition she had a large spleen. The blood counts then were as follows:†

	R. B. C.	Hg.	W. B. C.	Polynuclears.	Large Lymph.	Small.	Myelocytes.
August 15, 1908	8,000,000	100%	8,500	75%	12%	11%	2%
August 18, 1908	8,700,000	119%	11,000	73%	14%	11%	2%
August 31, 1908	9,000,000	110%	21,000	86.5%	13%	.5%	None
September 8, 1908	9,100,000	105%	17,750	86%	4%	10%	None

After this she was given *x*-ray treatment with no effect whatever on the blood count. She was discharged on September 15, 1908, slightly improved.

Shortly after this her symptoms returned with the same intensity as before her treatment, the spleen growing more rapidly. She kept at her household work until June 2, 1910, when she again sought hospital aid, this time at Mount Sinai Hospital on the service of my colleague, Dr. J. Rudisch. The only additional data in her history then obtained was that shortly after her leaving the Post Graduate Hospital she had some teeth removed, whereupon her gums bled excessively and that the bleeding was stopped with difficulty; that she also had some edema of the legs and eyelids and had become very constipated; that blood had appeared in her stools; that she had developed hemorrhoids; finally, she had become markedly emaciated. She remained at Mount Sinai unntil September 22, 1910, and returned again on December 17, 1910, when she came under my care.

The blood examinations were frequent and are recorded in the following table:

*Demonstrated at a meeting of the Medical Section of the New York Academy of Medicine, January 17, 1911.

The viscosity of her blood is 11.5.
Specific gravity is 1064.
The increase in volume was not determined. Centrifugalization of her blood shows that the serum content is not proportionally increased with polyglobulism.

The patient whom I now show you, as you see, has but a poor musculature and a very scant amount of subcutaneous fat. She is generally emaciated. Her lower eyelids are boggy. She shows her age especially by the presence of an arcus senilis. Her color, while not distinctly pale, is still not in any sense cyanotic. In fact the only parts of her body that are deeply red are her tongue, which she now shows you, and the palms of her hands, which you can see are livid.

When I press on her sternum, you notice, she cries out and gives every evidence of pain, and likewise we elicit pain when we strike the tibiæ. Bone tenderness then is easily demonstrated. You will find on making otherwise a physical examination that there is a slight enlargement of the left submaxillary lymph node, that her lungs show the evidences of an emphysema.

Her heart on examination will present a rough systolic murmur over the apex and transmitted to the left, evidences of a mitral insufficiency probably due to sclerosis induced by her disease. Since she had no clinical signs of cardiac disease and had no etiological factor for its production, I believe it a fair inference that the present signs of initial involvement of the mitral valve may be due to the dynamic causes produced by the probable increase in the volume and the actual increase in the viscosity of her blood, although a chronic nephritis, which is present, may be an additional factor.

Her pulses are equal, regular, of somewhat increased tension, which was demonstrated to be 155 by the manometer. She shows visible episternal pulsation as also of the vessels of the neck.

On looking at her abdomen a tremendous enlargement obtrudes. On examining this you will find a large, hard, fairly smooth mass extending from the ribs down into the pelvis on the left side, presenting an edge with a distinct notch at the umbilicus, which edge traced upward from this point goes under the ribs at the left parasternal line and traced downward curves from the umbilicus to the right side of the abdomen, limited to the right by the right mammillary line, from which it recedes to enter the pelvis behind the symphysis pubis. On palpating laterally to the left the mass can be felt extending behind almost to the vertebral line, where its border becomes lost. The mass is distinctly tender and moves with respiration; it is only fairly smooth. Slight eminences (two in number) can be felt, rather firm, about 4 cm. in diameter, one in front and one to the left laterally. They are probably anemic or thrombotic infarcts on the surface of the spleen, which organ this huge mass undoubtedly is.

On examining the liver you will find evidences

that its upper surface is at the fourth interspace and that the lower border can be distinctly felt 2 cm. above the umbilicus. The liver is therefore considerably enlarged. Its surface is distinctly smooth, and like that of the spleen very tender.

You will notice that the abdomen shows markedly distended branches of both the epigastric veins which lose gradually in diameter as they extend from the lower abdomen upward.

No ascites can be demonstrated. We would not want to say that it is not present, but owing to the colossal size of the spleen and the huge liver it cannot be proved. Due to the same cause are a procidentia uteri and prolapse of the rectum which this patient presents, the last associated with marked dilatation and thrombosis of the hemorrhoidal veins.

In other respects the physical examination reveals no demonstrable deviations from the normal.

The splenic enlargement has materially increased during the time the patient left Dr. Rudisch's service in September and the time she entered mine in December. The notes of the hospital records show that in September the most anterior border of the spleen extended to the umbilicus. Now you notice the border below the umbilicus over in the right abdomen close to the continuation of the right mammillary line. With this huge mass in her abdomen the patient does not complain much of the burden of its weight.

Dr. Osler, who has a large experience with this disease, on a visit to Mount Sinai Hospital last August, thought the spleen then was the largest spleen in erythremia that he had seen. What would he say if he saw it now!

We have, to recapitulate, a patient who, in addition to an erythrocytosis of between eight and ten million cells, a leucocytosis varying between twenty and forty-five thousand leucocytes, presents few features of a cyanosis, a much *relatively* diminished hemoglobin content, the color index being far below 1, who shows marked signs of bone marrow involvement with a colossal spleen and very large liver. The spleen is much larger than spleens in other affections excepting those found rarely in leukemia and more commonly in the Gaucher type of primary splenomegaly. But even in these affections I have never seen a larger spleen than this patient presents.

From the clinical evidence we must conclude then that this patient is suffering with the disease which has been variously called polycythemia with chronic cyanosis, splenomegalic erythrocytosis, splenomegalic polycythemia, myelopathic polycythemia, erythremia, erythremia megalosplenica, Vequez's disease, Osler's disease.

True it is that Vaquez in 1892 was the first to report an instance of the disease occurring in a patient in whom he thought he had demonstrated the existence of valvular cardiac disease. He reported it as a case "of a special form of cyanosis accompanying an excessive and persistent polyglobulism." (*Compt. rend. Soc. de biol,* Paris, 1892, XLIV, 384.) It was in a supplementary communication after an autopsy on this patient (*Soc. méd. des hôpitaux*, Paris, Jan. 25, 1895) that the absence of cardiac disease and the presence of a splenomegaly were established. To him belongs therefore the honor of describing the first case of the disease. The next reported cases were in 1899 by countrymen of Vaquez (Rendu and Widal) and (Montard-Martin and Lefas), then one by one of our own countrymen, Cabot of Boston, in the same year and again by him in 1900. The clinical entity of the disease was hinted at by Dr. Russell in his prefatory description of Saundby's case (Russel and Saundby, 1902). To Osler belongs the honor of placing the entity on a firm clinical basis in America and England. It would be wiser then to attach the name of Vaquez to the disease in honor of its discoverer, and of crediting Russell, Saundby, and Osler with establishing it as a clinical entity.

Numerous cases have occurred since then, but no case that I have been able to find presents the anomalous features of this one.

It had originally been contended that the cardinal features of the disease comprised a triad: cyanosis, splenomegaly, erythrocytosis. Since then numerous cases have been reported without cyanosis. This patient is another without that feature.

When we come to examine the data furnished by this patient's blood we will find some more remarkable and unusual features—features which make this case unique and worthy of report. First in importance are the signs of bone marrow stimulation. These signs would appear to indicate that in this case both the erythroblastic and leukoblastic activities of the bone marrow were called forth, because the red blood cells in addition to being far more numerous than normal show forms of degeneration and of regeneration, there being marked poikylocytosis and many nucleated forms of the normoblast type, and because the white blood cells are likewise markedly increased in number and contain forms, myelocytes, which usually obtain in bone marrow involvement. In addition to these there is marked bone tenderness which has not been described to my knowledge in this disease.

Thus you may observe that while the patient shows the characteristic features of erythremia, the unusual and colossal size of the spleen, the presence of a leucocytosis of 45,000, of which 2 to 8 per cent. are myelocytes, might suggest a leukemia of the myelosplenic type.

The occasional presence of myelocytes has been repeatedly reported in erythremia, as has a hyperleucocytosis with increased percentage of the polymorphonuclear form, but a persistent myelocytosis of 2 per cent. would seem to be extremely rare. It is hardly enough, however, to predicate the existence of a leukemia complicating an erythremia.

A word should be said about the classification of the white blood cells in this case. You will notice in the table the various headings under which the large number of non-granular mononuclear cells have been placed, as large lymphocytes, mononuclears, transitional. This was due to the difficulty in deciding what these cells of the large lymphocyte type really were. Perhaps they may be regarded as the progenitors of the myelocytes—myeloblasts, as they are called when found in the bone marrow. In the recorded autopsy of a case of Parkes Weber and Watson these cells were seen in large proportion in the bone marrow.

As to the theories advanced explanatory of the disease I shall say practically nothing except to call attention to the fact that all the cases reported present a *relatively* low hemoglobin content. If the hemoglobin percentages were the same as in normal blood we ought to have in erythremia with, for example, double the normal red blood count, 10,000,000 red blood cells, a hemoglobin of 200. This, however, is not a fact in these cases. The color index is always for below 1. The reflection might hence arise whether the hemoglobin being

relatively and absolutely diminished does not have the power of bringing sufficient O to the tissues to nourish them and that the bone marrow is therefore stimulated to supply a larger number of hemoglobin bearing cells so as to increase the number of O transformers. You are no doubt aware that one theory for the existence of the disease, suggested by Osler, I believe, is that its production depends upon a defective or perverted aeration of the blood. This would appear to receive support from the work of Koranyi and Bruce, who were able to reduce the erythrocytosis in this disease by the administration of O. The theory applies with greater force, perhaps, to the erythrocytosis accompanying emphysema, cardiac, and mediastinal diseases or associated with stasis from pressure on large venous channels. A serious objection to the theory propounded is the absence of evidences of bone marrow stimulation in *the* disease, which is, par excellence, one with reduced hemoglobin, namely, chlorosis.

PSYCHOSES OF CHILD-BEARING.*

By JAMES DUDLEY MORGAN, M.D.,

WASHINGTON, D. C.

PHYSICIAN, GARFIELD MEMORIAL HOSPITAL; CONSULTANT, U. S. GOVERNMENT HOSPITAL FOR THE INSANE, ETC.

If there is one disease which appeals more deeply to the sentiments of the medical profession, which wrings with anguish the heart strings of a family, which makes a sympathetic bond between friends and strangers alike, and causes all to shudder and mourn and pray, it is the picture of a mother with reason dethroned, not knowing, even abhorring, and with unnatural frenzy, injuring her own child. There is nothing more terrible or which appeals more strongly to humanity than a disease of this type.

We know, and alienists tell us, that there is no condition which shows more violent manifestations, one in which ideas run rampant, delusions and hallucinations work every nerve and fiber of the body, until unstrung, both mental and physical energy gone, the poor creature sinks, a stuporous, listless mass, bereft of all charm, beauty, wit, interest, cleanliness, and modesty.

Frequency.—Insanity is less apt to appear in women between 25 and 30 years of age, which may be considered the period of greater gestation, than at other times; still it occurs once in every 700 confinements. Most psychoses, one-half of all cases, occur in the first week of the puerperium, taking the puerperium as six weeks, 61 per cent. occur during that time; in 14 per cent. the psychoses began during pregnancy, and in 24 per cent. during lactation; and most of these cases were in the first three months. In a study of 1,000 cases of insanity in women by Ballintine, 457 of these had borne children. In 141 cases, 30 per cent., the onset of the psychosis occurred either during gestation, puerperium, or the lactation period.

The statistics of insanity in women admitted to the Government Hospital for the Insane during the past two years have been kindly furnished me in the following letter from Dr. O'Mally:

"Dear Doctor: In looking over our statistics for the course of two years, including the period between July 1, 1908, and July 1, 1910, there were 328 women admitted. Among these were 18 cases in which the exciting cause was due to gestation, puerperium, or lactation. Of these 18 cases, 11 suffered from dementia precox, 6 from manic-depressive insanity, and 1 from anxiety psychosis, which is allied to the latter form. Hoping this will be of some assistance to you, I am.

"Very truly yours,

"M. O'Mally."

Present Status.—For many years the classification of the insanities was very unsatisfactory in every particular. It not only lacked a basis in fact, but was unscientific and cumbersome. All the states of depression were denominated melancholiæ; those of excitement were called maniæ. As a result there crept naturally into this classification many different kinds of manias and melancholias, depending upon the duration of the disorder, the supposed cause, and the whim of the writer.

Hence it happens that when we speak of the insanity of childbirth we think at once of puerperal mania. We have been taught for years that such a disease exists and think we are familiar with its manifestations. Very rarely, indeed, is reference made to any other form of alienation occurring at this particular period of a woman's life, but it is now recognized that various forms of insanity then occur. Kraepelin, the great German psychiatrist and father of the present school of psychiatry, gave a clear and accurate description of mental disorders; placed at the disposal of the profession definite diagnostic points and rendered the prognosis simple. In accordance then with his classification and conception, the insanities of the child-bearing period are different in no way from the same disorders occurring at other periods of life or in the other sex. The relations existing between childbirth and insanity is one of cause and effect. There is nothing characteristic about the resulting insanity; there is nothing abnormally potent in the determining cause. The same psychoses might readily result in the same individual, following a severe surgical operation or any great psysiological upheaval. The term puerperal mania is a misnomer and should be relegated to the past. All forms of insanity do not occur at this particular time of a woman's life. Obviously the involutional psychoses (the true melancholia and the senile group) and paresis could not reasonably be expected to occur. Those most frequently seen are: (1) Anxiety psychosis; (2) Collapse delirium (infective and exhaustive psychoses); (3) Dementia precox, and (4) Manic-depressive insanity.

(1) This first group, with its characteristic anxiety, apprehension, and depression, occurs as a rule in psychopathic individuals prior to confinement. Without just and sufficient cause these patients look forward with great dread to the approaching confinement. Their fear of what is about to happen is abnormally intense; to them hemorrhage is an unavoidable accident; pain is an insurmountable object. They reason with themselves; argue that thousands of women have gone through the ordeal and that there exists no real reason for fear, yet they desire to be constantly assured. Accompanying this anxiety is marked depression, insomnia and motor-restlessness. It is not to be understood, however, that every apprehensive woman is suffering from an anxiety psychosis. It is only when the morbid ideas dominate every act and thought of the individual that the state be-

*Read before the Obstetrical and Gynecological Society, Washington, D. C., December 16, 1910.

comes abnormal. At the birth of the child, these patients, as a rule, become normal.

(2) Collapse Delirium.—In neurotic individuals the so-called collapse delirium may follow childbirth. The course is short, rarely lasting more than two or three weeks, and frequently terminating abruptly. The beginning is marked by a dreamy hallucinosis with delirium and marked insomnia. Soon motor-restlessness occurs. Their movements are the result of impulse. They remove their clothing, injure themselves, and destroy objects about them. Disorientation becomes absolute. They fail to recognize their relatives and friends; do not know whether they are at home or abroad and have no idea of time. Frequently they refuse food and offer a blind resistance to everything done for them. The delirium is most intense.

(3) Dementia Precox.—Of all the disorders which accompany childbirth, this, perhaps, is the saddest, because the prognosis is uniformly bad and it responds less readily to treatment. So-called recovery may occur, but a close examination reveals the existence of defects which will remain forever. The symptomatology is most complex, and to attempt a full description of the disorder would be almost equivalent to writing a text book on the subject. Frequently the onset is characterized by depression, apprehension, and suspicion; hallucinations of both sight and hearing are present and the delusions are of a foolish character. Consciousness, as a rule, is not much disturbed and orientation is good. The memory from the beginning is enfeebled, and the enfeeblement is rather in the nature of a progressive deterioration. Attention is impaired and the acquisition of knowledge is retarded. There is a well marked indifference and a lack of interest in home and friends. The patient becomes careless in dress and untidy in habits. Impulsive attacks, leading to suicide or homicide, may occur.

(4) The Manic-Depressive Syndrome.—Here we have states of excitement and depression. These states may alternate, giving us the pure disease. If the state of excitement only occurs, it is spoken of as the excited form; similarly, if depression only exists, the disorder is spoken of as the depressive form of manic-depressive insanity. Close examination, however, will generally reveal the existence of both states. The emotional tone is most unstable and may vary or change within a few minutes from joy or sorrow, carrying the individual from laughter to tears. When excited, there is an ultra-productivity of ideas and a pressure of activity. In the depressive form there is a delaying of thought, accompanied by retarded activity. The prognosis in this disease is good. The majority, if, indeed, not all, make a good recovery.

The following is a brief history of a case of the mixed form of manic-depressive insanity, recently under observation:

Mrs. X*., 27 years of age, of German extraction; no insanity in family. Her personal history shows she was normal as a child; was bright at school; learned rapidly and graduated from the high school at the age of 19. No alcohol or drug addiction. Had the usual diseases of childhood and typhoid at the age of 15. Married in her 22d year. In her 24th year gave birth to first child; labor normal; no after trouble. Her second child was born October 20 last. Everything progressed normally until November 2, when she began to see spirits; saw an aunt who had been dead for 10 years; delusions then developed; she became possessed of the idea that she had a great deal of money; wanted to build, furnish and endow a hospital; spoke of buying houses as Christmas presents for her friends. She was unable to sleep at night, became restless, began to sing. As the process progressed she became more excited, exceedingly noisy and boisterous, constantly slapping herself, pulling her hair, tearing the bed clothing, etc. The lochia not being natural, and believing her condition was caused by infection, the womb was curetted, but without benefit. During the past 10 days her excitement has subsided, her delusions have faded, and she is apparently progressing toward recovery. The following stenogram of the patient's remarks shows a flight of ideas, distractability and a well-developed tendency to rhyming and sound-association:

"I don't know . . . Don't call me Mamie . . . You're an old gas-bag. I can't spell.

"One, two, three, four, five, six, seven,
All good children go to heaven.

"He was a fool . . . He thought I was really flirty, but I wasn't. I am tired of Hercules. I never loved but one old glass-eye. He wanted to kiss me. I said:

"I'd rather sit on you proper
Than say medicine dropper,
You dirty old stopper.

"I don't mean you; that's Bill's hat; in it is a tomcat. No; I am not a tomcat, I am a tomboy. (Looking out of the window). "She said she would teach me to paint. I love fresh air and flowers, sunset and winter. No, sir; she was right and I was dead. (She sings.)

"God said 'Mary, come to Jesus,'
Mary said 'No';
God said 'Mary, come to Jesus.'
I said 'Go.'

"The doctors are pluperfect Perfecto, but they can't fool me. Rivers run rubies and rubies run red. Tra-la, you heard what I said. (Laughing.) I'm a riddle, you're not; I'm a drunkard, you're a sot. Riddle-de-rot."

During the taking of the stenogram she was in a state of constant psychomotor excitement; slapping herself, rubbing her arms, folding herself in the blankets, patting the pillows, etc. During the attack she had had each day a period of depression, coming on quite regularly in the morning and lasting about one hour. When depressed she cries incessantly. There has been no tendency to suicide or self-mutilation.

Treatment.—The careful guidance and treatment of our patient will go far towards delaying or lessening the psychoses of pregnancy. Those that have manifested previous psychoses should be carefully watched.

Those of a manic-depressive or of precox type should not bear children, and if unfortunate enough to again become pregnant, a termination of the pregnancy as early as possible is to be considered and is recommended by some.

Proper nursing and isolation, if necessary, will restore 80 per cent. of those of dementia precox type within six months or less, and 8 per cent. more within the year. Careful dieting, hydrotherapeutics, such as the wet pack or continuous immersion, with the avoidance as much as possible of all narcotics and sedatives, will do much to hasten the recovery of our patient.

*Reported through the courtesy of Dr. B. R. Logie.

Conclusion.—A few facts from observation and research have been deduced; that puerperal mania is not a diseased entity; that a psychosis developing during pregnancy is apt to continue until completion of labor; that psychoses in multiparæ were slightly more than in primiparæ, the proportion being 15 to 13; that age has not as much influence as is supposed; that there is no telling why one woman is exhilerated and another depressed; that eclampsia and toxic infection are not more frequent with manic-depressive insanity than in women of normal mentality; that it is most difficult to say if pregnancy will produce a psychosis and whether it will occur in the puerperium or in the lactational period; that the mortality among children born of insane mothers is very great; that negroes seem not to develop psychoses after miscarriages as readily as the whites.

919 Fifteenth Street.

ACUTE URETHRITIS OF CHEMICAL ORIGIN, WITH REPORT OF THREE CASES.

By WILLIAM J. ROBINSON, M.D.,
NEW YORK.

One of the most unfortunate terms in our medical nomenclature is the word gonorrhea; besides the fact that its etymologic derivation is absurd, it makes us link, against our will, every form of urethritis with the gonococcus, so that the word urethritis has practically become synonymous with gonorrhea or gonococcal infection and we therefore often forget that there is such a thing as urethritis of non-gonococcal and even non-bacterial origin.

There is nothing strikingly original in the statement that urethritis may be of chemical origin. Everybody knows, or is supposed to know, it. Still this is often forgotten. The fact that it, *i.e.*, the possibility of a chemical cause of urethritis, was forgotten or overlooked in two cases and that the third case—which I will report first—presents some rather unusual features, is the apology, if apology be needed, for this brief report.

Mr. X., 28 years old, was to be married on September 21, 1910. Just a week before, September 14, he considered it necessary to cohabit with a prostitute. Men of a certain class seem to regard it a sacred obligation to bid *adieu* to their bachelorhood in this dastardly manner. The temptation is very great to break out in a tirade against the brutes, who, a few days, sometimes even a few hours, before going to the marriage bed, will subject themselves and their future wives and children to the risk of infection, because, forsooth, after marriage they intend to be faithful to their wives and therefore want to have a "last fling." But what's the use? The brutes don't read medical journals, and if they do they are not affected by our tirades. And so Mr. X. had intercourse on the 14th. On the 16th he noticed, or thought he noticed, a tickling in the urethra. After a few hours the tickling disappeared. On the 17th he thought it returned. In view of the close approach of the important day he became thoroughly frightened—though I believe there was really nothing the matter with him, the tickling being more in his mind than in his urethra—and consulted—a reputable specialist? No; a druggist. The vast majority of druggists I am familiar with are men of high standing, well up in their profession, who would disdain to prescribe or even to advise in cases of venereal disease. But there are black sheep everywhere, and there is no question that some druggists are as ignorant as they are impudent. This druggist seems to have been particularly ignorant. His advice to the patient was to dissolve one antiseptic tablet (containing 7.7 grains of corrosive sublimate!) in *about* half a glass of water and syringe three times a day, using several injections for each seance. I have known druggists advising the insertion into the vagina of 7-grain corrosive sublimate tablets as an anti-conceptional measure (and more than one woman paid a severe penalty for this stupidly criminal advice), but I had not heard of anybody displaying such dangerous ignorance.

The patient did as told and syringed out his urethra four or five times with a half-ounce syringe. This was before going to bed. He suffered agonies the whole night, and the pain at any attempt at urination was so severe that he abstained. The following morning he applied to me. The penis was four or five times its normal size. The swelling and edema were enormous. The glans was so puffed that it was difficult to find the meatus. The patient was badly frightened, but constitutionally he was not ill; no fever, no malaise, no stomatitis, no bad odor; in short, no symptoms of mercurial poisoning. He showed me the tablets which the druggist had given him; they where, as stated, 7.7-grain corrosive sublimate tablets, combined with an equal amount of ammonium chloride. He indicated to me the amount of water in which he dissolved the tablet and the amount was between four and six ounces. In other words, the strength of the bichloride solution which he used as a urethral injection was about 1 in 250 to 1 in 350. And in all he used about 3 grains of corrosive sublimate; but, of course, he let the injection run right out. That there were no systemic symptoms I ascribe to the fact that the strength of the solution by necrosing the mucous membrane prevented the absorption of the poison; the effects therefore were purely local. That his bladder was apparently not injured, I ascribe to the fact that he injected gently and did not force open the shut-off muscle.

He tried to urinate unaided, but failed. I then with great difficulty anesthetized the urethra, passed a small catheter, and withdrew twenty-two ounces of urine. The patient at once felt relieved. For the penis I ordered compresses of liquor alumini acetatis (Burrow's solution); to do away with the strangury I ordered rectal suppositories of morphine sulphate (gr. ¼) and atropine sulphate (gr. 1-60); also, internally a mixture of potassium bromide, potassium acetate, arbutin, and fluid extract of triticum; also to drink frequently of a cold infusion of linseed (made as follows: Macerate a teaspoonful of whole linseed in a glassful of water for five to ten minutes, stirring occasionally; strain, and add a dash of lemon juice to take away the otherwise "flat" taste of the linseed; the demulcent effect of this rather old-fashioned infusion is not known as well as it deserves to be). This treatment improved the patient's condition at once. The swelling went down considerably; the pain and burning on urination disappeared almost entirely. But on the next day a profuse thin discharge made its appearance and the urine contained numerous flocculi. The patient was, of course, sure he had gonorrhea, but I was convinced of the contrary. Numerous examinations failed to disclose a single gonococcus or a gonococcus-like dip-

lococcus. It was pure—one might say chemically pure—pus, caused by an irritating antiseptic. I used no local treatment whatever—only internal demulcents and mild diuretics, and the discharge gradually diminished; it is now reduced to the fraction of a drop in the morning, simulating the morning drop of gonorrhea, and the urine contains flocculi; they are, however, entirely different from Tripperfäden and they, as well as the minute discharge, are entirely free from any cocci. The wedding, which was necessarily delayed for a month, is to take place in a few days and I have no hesitancy in giving him my unqualified permission.* During one period in the treatment there seemed to be a tendency to the formation of stricture, but several dilatations with Kollmann's dilator, followed by the instillation of a 1 per cent. solution of thymol iodide in oil, restored the urethra to its normal caliber, and it is now perfectly normal in this respect.

The second case concerns a young man who was suffering with too frequent nightly emissions and who was advised to use an injection of zinc sulphate as a remedy. The prescription called for zinc sulphate, 2 drams; water, 1 pint. After using this injection for two weeks he noticed a slight thin discharge; he thought this was semen (!), and increased the frequency of the injections. The discharge then increased, becoming thicker, according to his statement. He then went to a physician, and in spite of telling him the history of the case, in spite of assuring him that he had never had intercourse in his life, the doctor proceeded to treat the case as one of gonorrhea. (We are sometimes too ready to consider our patients liars.) He never examined the discharge, but gave him the regulation treatment of copaiba and santal oil internally and potassium permanganate as an injection; later on he changed the potassium permanganate to an organic silver preparation. Under this treatment the case was getting gradually worse, the discharge was increasing and so were the nightly pollutions, and what is worse, the patient developed a stricture. When he applied to me for treatment the discharge was thin, but profuse, and no gonococci whatever, after numerous and repeated examinations could be found. About 2½ inches from the meatus there was a stricture, which permitted the passage with some difficulty of 18 F. I told him to discontinue all treatment for ten days and present himself at the end of that period. He did. His discharge had diminished materially, being only a few drops in the morning and practically nothing during the day. I then began to dilate his stricture, which yielded completely to twelve dilatations. The only other local treatment I gave him was the instillation of a dram of a 1 per cent solution of thymol iodide in olive oil. The stream of urine became normal, the discharge disappeared, with the exception of a minute drop in the morning, which also finally yielded to small anterior injections of 5 per cent alcohol (alcohol U. S. P. 1 part, distilled water 19 parts). I have not seen the use of alcohol as a remedy against urethral discharges mentioned anywhere, but it has rendered me good service in some very obstinate cases. In some instances I use it 10 to 20 per cent strong and even stronger.

The third case was one of what I call silver-nitrate urethritis, of which thousands and thousands of cases walk the land, and I report it, not because of its rarity, but because of its commonness, in order to call attention as forcibly as I can to a form of malpractice very prevalent in our profession; well-intentioned malpractice, but malpractice, nevertheless. I refer to the custom, handed down to us from former decades, of "testing" the reality and permanence of a gonorrheal cure by injecting into the urethra a strong solution of silver nitrate. And if there is anything I am convinced of in the handling of genitourinary cases it is that many a cured case of gonorrhea may become, by repeated injections of silver nitrate, converted into a rebellious or practically incurable case of chemical or bacterial urethritis. In the early days of my practice I was guilty of the same practice and more than once have I injected a, to all intents and purposes, cured case of gonorrhea—no discharge, no gonococci, no shreds—only to have the patient come back with an obstinate discharge, which it took weeks and often months to cure; and after each "testing" the discharge was less and less amenable to treatment. And I state it as my positive opinion that thousands of people are walking the earth with urethral discharges which were caused by assaulting the urethra, weakened by gonorrheal infection, with an irritant chemical, and who would have remained perfectly well if their urethra had not been subjected to any such heroic tests. The late Lassar was the only one of the "big" men whom I heard condemning the silver nitrate test in most unequivocal language. I trust that these lines may have the effect of inducing some colleagues to discard the test altogether, or, at least, to be very cautious and mild in its application.

The case I am to report is a clear-cut case of silver nitrate urethritis. Mr. O., 22 years old, noticed a urethral discharge on May 22, 1908. It was the first time he ever had any trouble. He came to me for treatment May 23. Examination showed the presence of numerous gonococci. Under the treatment the discharge completely disappeared in three weeks. I kept him under observation for three weeks more and then discharged him cured. I use the word *cured*, because contrary to the opinion of some urologists, I believe that gonorrhea can be as perfectly and as radically cured as many other diseases, say chancroids or eczema, or scabies. There was absolutely no discharge; the urine was clear of shreds, the expressed secretions from the prostate and the sediment from the centrifugalized urine showed no gonococci, and I told him that I considered him perfectly cured. I felt especially justified in doing this, because at no time were there any symptoms of posterior involvement and I felt sure that the infection was all the time limited to the anterior portion. To the question whether he could marry safely, I replied in the affirmative. "But," I said, "if you want to feel at perfect ease, come a month or so before you intend to get married and I will give you again a thorough examination." And this was the last I saw or heard of him until October, 1909. He became engaged in the spring of that year and the wedding was to take place in September. Early in August he called at my office to be examined, but was told

*The patient was married on November 1: on the 18th he reported himself as perfectly well, and an examination failed to disclose any pathological condition, except that the urine still contained a few small sterile flocculi.

that I was away in Europe and would not return until the beginning of October. He then went to another physician, to whom he told the entire history of the case. And he also told him that I considered him perfectly cured and he considered so himself, because during the thirteen or fourteen months his urine had been perfectly clear and he had no symptoms of any kind.

The doctor proceeded to apply the beer-silver test. Though the patient was not a beer drinker and detested beer, he was told to drink several glasses of beer for three evenings in succession. This produced absolutely no effect. The doctor, however, was not satisfied with this test, but proceeded to inject silver nitrate. I never could find out what the strength of the solution was, but the patient said that the pain was intense, and several hours later the urethra began to discharge. This was taken by the doctor as positive proof of gonorrhea, which he proceeded to treat. He treated the patient both internally and by injections, and he treated him very vigorously. But when he came to me two months later, in October, his discharge was, according to his statement, worse than ever. I subjected the discharge to numerous examinations, all of which were negative as far as the gonococcus was concerned. I discontinued all treatment for a month, with the exception of advising him hot sitz-baths. The discharge had diminished by the end of that period, but it was slow work to stop the discharge entirely; it took five months before I could pronounce him cured. Examinations for gonococci, undertaken at different periods, all proved negative.

Here a man had to suffer pain, annoyance, anguish, and great expense for seven months as a tribute to an old brutal test handed down to us by sanctified tradition and accepted by us without criticism, without analysis. There are only too many such cases. And if, as is often the case, a bacterial infection becomes implanted on the originally sterile discharge, then we have to deal with a bacterial urethritis, which is sometimes more rebellious to treatment than a simple gonorrheal urethritis.

I should like, in conclusion, to emphasize the following points:

1. Urethritis of chemical origin is more common than is generally supposed.

2. While most cases are caused from self-administered injections prescribed by barbers, friends, and others, some cases owe their origin to the overzealousness of physicians.

3. The unscientific and unjustifiable silver nitrate test, which should be forever discarded, has been responsible for very many cases of chemical urethritis.

4. The diagnosis of chemical urethritis is made by the history of the case, the freedom of discharge from gonococci and, generally, its improvement on being let alone.

5. One of the most useful agents in the treatment of chemical urethritis is warm sterilized olive or almond oil, or a ½ to 1 per cent. solution of some organic iodine derivative (iodoform, dithymoliodide, isobutylorthocresoliodide) in one of the above oils.

Tendency to stricture should be prevented by dilators or by sounds dipped in the just referred to solutions.

REMOVAL OF THE SEPTAL FLOOR IN SUBMUCOUS OPERATIONS.

By ALFRED KAHN, M.D.,

NEW YORK,

SURGEON HARLEM DISPENSARY, ASSISTANT (OTOLOGY) NEW YORK EYE AND EAR INFIRMRY, ATTENDING PHYSICIAN UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE DISPENSARY.

It is my desire to present to the profession a few individual details in regard to the above operation which may be of value to other submucous operators. I refer more particularly to the removal of the septal floor. The technique of this, to many operators, has been most difficult, and is the subject of much discussion at the present time.

The most careful attention to detail should produce the best results; most of the large tears in the septum which have come under my observation are caused by operators having attempted to and only partially removed the floor. In operations where the result is poor it is generally due to failure of removal of the bony and cartilaginous spurs on the floor. Where forceps are used the floor is very imperfectly removed, and the liability to tear comparatively great. I use a grooved chisel with notched point and dull outer edge. My method follows:

We know that at the point where cartilage and bone come in contact, or at the line where the perichondrium covering the cartilaginous septum and the periosteum covering the lower bony septum meet, there is an extremely tight adherence of both to the septum. In other words, the periosteum is more firmly attached to the bony septum than the perichondrium is to the cartilaginous septum. Therefore, while it is quite easy to elevate the perichondrium from its cartilage, it becomes an entirely different matter to separate the periosteum from the bone. It is for this reason that forceps are practically useless and apt to produce tears. The chisel is to be preferred. The forceps may easily seize a small piece of hanging perichondrial or periosteal tissue, and when the operator bites and pulls out he is very apt to bring away this tissue with its overlying mucous membrane. This often produces a perforation.

After removing the upper cartilaginous septum (in the usual manner), insert the chisel downward at an angle of from 45° to 60°; then use the mallet and drive the chisel till it strikes bony tissue, and then, with the chisel as a lever, elevate the cartilage out of the groove between the two palate processes of the superior maxillary bones. Now, instead of pulling this elevated cartilage directly out, grasp it in a pair of Killian or Knight forceps and push it backward. This movement *peels* the perichondrium from below, and all the *tension* is placed upon the firm periostium.

In this way the spur (cartilage and bone) is safely removed. Then insert the chisel and remove any bony projections on the septal floor. In taking out these spicules of bone I always proceed by first pushing them backward or upward (as described above) in order to peel them from the periosteum.

These simple details have been of inestimable value to me and have greatly improved my results.

New York, April 8, 1911.

WEIR MITCHELL ON WILLIAM HARVEY.

It was a rare privilege to be present at the concluding lecture of this season's course delivered before the Harvey Society, at the New York Academy of Medicine, April 1, 1911. The lecturer was the distinguished physician and author, S. Weir Mitchell, who presented many new and interesting facts bearing upon the personal side of the immortal Harvey. It was All-fools' Day, three hundred and thirty-three years ago, when the Englishman who blazed the trail of modern experimental medicine was born. Although a great deal has been written about his scientific contributions, very little has been known about his private life. In this respect he resembles his contemporary, Shakespeare. Another interesting coincidence is to be noted in the fact that while it has remained for an American to discover many details in the life of the English poet, it is also an American, Weir Mitchell himself, who has unearthed many facts in the life of Harvey that have been hidden even to his own countrymen.

Only the trained literary eye could perceive and the pen portray, as Mitchell has perceived and portrayed, the dramatic moments in the life of the discoverer of the circulation of the blood. Under the wizardry of the lecturer's sparkling narrative the hearer was transported to the days when Harvey was a student in Padua or a busy practitioner in London. With what solemnity in those days was invested the ceremony of conferring the medical degree. One could picture the young Englishman receiving for a moment the golden ring of the ancient University upon his finger, and the kiss upon both cheeks, which were the necessary accompaniments of the conferring of the diploma. This was quite unlike the large parchment of to-day; as its name signifies, it was a folded manuscript, beautifully illuminated with the private seal of the recipient. Dr. Mitchell exhibited a fac-simile of this diploma, which Harvey must have carried back to his native land with considerable pride. He carried as well the anatomical love that he had acquired from his master, Fabricius, whose demonstration of the function of the valves of the veins guided Harvey to his future epoch-making discovery.

Nowadays one little thinks of Harvey as the busy London practitioner, who nevertheless had time to conduct his private anatomical courses, to make his hospital rounds, and to teach his classes of medical students, in addition to carrying on his numerous investigations. What a contrast to the modern investigator who must perforce surrender his private practice if he would gain any success in experimental work! The acquisition of wealth did not wean Harvey from his activities as a physician and as an investigator. In his career there were none of the traits so common in scientific workers of to-day: the haste to publish results and the willingness to be "interviewed." It was many years after Harvey conceived the idea of the orderly circulation of the blood before he permitted it to be transferred to the printed page. Although he lectured to his students upon this subject as early as 1619, it was not until 1628 that his work, "Exercitatio de Motu Cordis et Sanguinis in Animalibus," a quarto of 72 pages, was published at Frankfort. His experiments were performed on living dogs, and since there were no anesthetics in those days, his work was naturally most difficult. In spite of this, and in spite of the opposition of the schools, and probably of the anti-vivisectionists of those days who had more justification for their cause than their deluded descendants of to-day, Harvey succeeded in convincing his own generation of the truth of his discovery. A contemporary allusion humorously compares Harvey's work with that of Copernicus; the latter showed that the earth moves in a wheel; the former showed that the blood also moves in a wheel. In his later years when Harvey had gained distinction as the physician to two successive kings, his love for experiment did not abate. Although fortune smiled upon his ventures, he felt keenly the misfortunes of his royal master and patient, Charles the first. Nor did he escape the vindictiveness of the parliamentarians. It was a melancholy day for Harvey when he learned that his house had been ransacked by his political foes and that his precious manuscripts, representing many years of labor, particularly on the development of insects, had been destroyed. One pathetic incident in his later life reflects the rigorous customs of the age in which he lived. While traveling in Italy he had forgotten to bring with him a certificate stating that he had not been in a plague-infested town. Failure to produce the certificate was the cause of his enforced quarantine for three weeks, in an open field, on a litter of straw. One can picture the plight of the gouty Englishman, the physician of kings and the ward of princes, appealing in vain for release from a cruel quarantine imposed by a panic-stricken community. Dr. Mitchell read extracts from Harvey's letters written at this time, which show that, when angry, Harvey wrote abominable English. The pangs of sciatica were not conducive to that elegance of literary style which Harvey commanded on other occasions.

The limitations of time prevented the lecturer from presenting all the results of his investigations into the life and character of Harvey. These will be published in the near future, including letters that have been locked up in English archives for many years, and had never been read excepting by those by whom they had been written and to whom they had been addressed. This promises to

be a literary sensation. It is fortunate that one of Dr. Mitchell's eminence has essayed the task of studying the life of Harvey from original sources, and of adding to the meagre knowledge the world possesses of this pioneer of modern scientific medicine.

AGAIN THE DISPENSARY ABUSE.

Poverty and sickness will always abide with us, and not rarely in association. Therefore, means will have to be devised from time to time, in accordance with changing conditions, for their prevention, amelioration, and correction. In the relief of the poor sick the dispensary has proved a most useful and beneficent influence, but, like all agencies for good, its privileges have not escaped abuse. The questions of poverty and its relief have received scientific study and treatment, but the care of the poor sick has not yet been given the full and intelligent consideration its importance demands.

An interesting and comprehensive discussion of the dispensary abuse took place recently before a largely attended meeting of the Philadelphia County Medical Society and the multifarious aspects of the subject were presented by a large number of speakers, including physicians affiliated with dispensaries, as well as others not so affiliated, and also a representative of the Society for Organizing Charity. It was agreed that such abuse exists, but it was evident that widely different impressions of its degree and extent prevail. The abuse is perhaps most flagrant in institutions connected with medical colleges, where clinical material for teaching purposes is required, and it is especially conspicuous in the realm of the specialities, including surgery. It represents the gratification of a human desire to secure something for nothing, and it is in no small measure contributed to by physicians themselves, when they refer private patients to dispensaries for diagnosis and treatment. On the other hand, it was pointed out that there is considerable diversity in the fees charged by different physicians, and the sick person in modest circumstances is placed in a position in which he has to decide whether he shall avail himself of the privilege of being treated gratuitously by a physician of recognized skill, ability, and experience, whose fee he may not feel able to pay, or be compelled to submit to treatment at the hands of some other physician of lesser skill, ability, or experience whose fee he can afford to pay. The personal appearance and attire of the patient is, of course, no guide as to his ability to pay for medical services. Sometimes even the family income cannot be depended upon as an index, for expenditure may exceed income; and families no less than communities do not always work in unison, and the stronger may not be willing to assume a part of the burden of the weaker.

Admitting the existence of the abuse, which works to the ethical deterioration of the beneficiary not less than to the material detriment of the medical profession, what shall be the remedy? It is not desired that any worthy or deserving poor person should be deprived of gratuitous medical attention, but who shall decide whether an applicant for treatment can afford to pay, and how much he shall pay? This is the crucial point of the situation, but it should be possible to establish a working standard by which a decision can be reached in the given case. Here is the opportunity for the social worker. Every applicant for medical charity should, before being received for treatment, be asked whether he can afford to pay for a physician's services or not. If the answer is in the affirmative he should be referred to a physician of his own selection; if in the negative he should be tentatively accepted, his case meanwhile being placed in the hands of a trained worker for investigation and decided on its merits. This plan has been tried at a number of dispensaries in New York and elsewhere, and while not perfect in its results has, nevertheless, served to lessen the evil where it has been systematically employed.

There can be no doubt that as a result of the dispensary abuse the young practitioner is deprived of a not inconsiderable and much-needed income, to which he is properly entitled, while the public is at the same time and to a corresponding degree being demoralized. It is time that the abuse should be lessened, if not entirely corrected, and the common injury stopped. To this end there must be uniformity and harmony of action.

THE NEED OF MORE PRACTICAL EXAMINATIONS BY STATE BOARDS OF REGISTRATION IN MEDICINE.

There has been during recent years, and particularly during the past year or so, an uneasy suspicion, amounting in some cases to a conviction, that medical practitioners are sometimes licensed in this country who are not competent to fulfill their duties to the benefit of the community or to the satisfaction of themselves. Within the past year this feeling of dissatisfaction with the methods of training medical students in vogue in some parts of America has been voiced quite freely and suggestions have been made designed to ameliorate the status of the medical profession. In the *Old Dominion Journal of Medicine and Surgery*, February, 1911, Richard C. Cabot of Boston deals anew with the subject. He suggests two possible remedies, one of which can be applied at once, while the other cannot. The one which cannot be employed is that the standard of most of the medical schools be raised immediately, without waiting for the normal and healthy growth now going on to come to maturity. Therefore, the author says there is but one thing to do, namely, to make practical and consequently more searching our existing State examinations for the right to practice medicine. The majority of such examinations are at the present time entirely in writing, and although most States insist upon proof of a fairly good preliminary and medical education, it is still possible in some States, according to Cabot, for a man to become qualified who has never seen a sick patient, never attended a woman in labor, never dressed a wound, and never written a prescription in his life.

As the author points out, a training of this description is wholly inadequate, nor is it fair to the

general public to allow an individual so imperfectly equipped for the practice of his profession to treat patients and prescribe drugs. In order, therefore, to test a person's medical knowledge properly, practical examinations are needed, and in order to be able to pass such examinations a practical training will be essential. It is no preposterous demand to insist that before a medical student becomes qualified he should be compelled to give evidence of his ability to treat ordinary diseases and injuries. Indeed, such a demand is inspired by sound common sense and tests of this nature are compulsory in Great Britain and in other European countries. A few States have already adopted practical tests for the examinations of their candidates, and the more quickly other States follow their example the better it will be.

Hysterectomy in Pregnant Tuberculous Women.

It has long been held justifiable to interrupt pregnancy in a tuberculous woman, especially in laryngeal tuberculosis. But heretofore the method of ending gestation has been the induction of abortion or premature delivery, in which forms of intervention considerable loss of blood is involved, convalescence is protracted, and the woman may again conceive. Henkel, before a recent meeting of the Society of Physicians and Naturalists of Jena (*Münchener medizinische Wochenschrift,* February 28), reports two cases of advanced tuberculosis, in one of which the larynx was involved, in which he performed total abdominal hysterectomy under lumbar anesthesia. The risk is small and the operation itself is bloodless, while convalescence is prompt. The operation is suitable to any stage of pregnancy. Bennecke claimed in discussion that this resource gave the child no chance, when its survival was possible. He also urged that in miliary tuberculosis interruption of pregnancy was contraindicated. Henkel thought that infants of mothers with miliary tuberculosis or bacillemia were foredoomed to die of that disease and that hysterectomy could therefore do no harm to the next generation, while it at the same time effectually sterilized the mother and prolonged her life. Seige urged that in the interest of forensic medicine stricter indications should be laid down, but Henkel said that each case is a law to itself.

Insufflation of Oxygen in General Peritonitis.

Oxygen blown into the peritoneal cavity through the drainage tube in general peritonitis has a mechanical action in preventing adhesions, as well as a bactericidal action, and has been found of considerable value. Weiss and Sencert of Nancy published their results in May, 1910, and S. Banzet records another case treated in this way in *La Presse Médicale* for February 1, 1911. In Banzet's case the peritonitis resulted from a ruptured parasalpyngian abscess, which was drained after laparotomy, and the use of oxygen commenced at once. All the signs of an alarming condition of a few hours before were changed by the operative procedure and the oxygen treatment with which it was followed. The continuous use of the gas aids in the removal of fluids from the abdomen, and improves the general condition of the patient remarkably. The amount of secretion is increased by this process, which is auxiliary to the drainage. The oxygen kills all the anaerobic microorganisms, or arrests their multiplication. It also diminishes the virulence of the aerobics and the activity of their toxins. An increased hyperemia produced by the oxygen favors phagocytosis. The absorbed oxygen acts as a stimulant to the cardiovascular system and the respiratory apparatus; it combats the intestinal paralysis and increases kidney action, and the resultant diuresis helps to carry off the infectious products. The tubes should be so arranged that the gas will pass to the lowest portion of the abdominal cavity. It should run slowly and may be taken from an ordinary tank or from rubber bags.

Differences Between Septic and Scarlatinal Streptococci.

It is claimed that in parts of Asia typical mild scarlatina occurs which is not transmissible. If this is the foundation for scarlet fever as we know it we have only to assume that this benign affection furnishes a basis for the flourishing of a virulent form of streptococcus. The question has usually been "What is this streptococcus?" Is it identical with the coccus of streptococcic sepsis? The problem raised is much the same as in erysipelas. At a meeting of the Scientific Society of German Physicians of Bohemia held last October, Schleissner and Spät discussed the differences between the bacterial origins of scarlatinal and streptococcic sepsis (*Deutsche medizinische Wochenschrift,* February 2). The cocci of scarlatina are non-virulent in animal experiments, however much we seek to increase their pathogenicity. Further, as a corollary, we find that animal serum and leucocytes destroy the scarlatinal coccus. The lesson to be learned is this: perhaps scarlatinal bacteriotoxins should be prepared only from scarlatinal cocci. The authors do not belittle the use of serums from septic streptococci in the treatment of scarlatina; but believe that the entire subject must be restudied by testing serums made from streptococci obtained from mankind which answer the biological tests above cited.

News of the Week.

Health of the Canal Zone.—The report of the Department of Sanitation of the Isthmian Canal Commission shows that during the month of January, 1911, the total number of deaths from all causes among employees was 40, half of which were due to disease, half to violence. This gives an annual average rate per thousand of 10.14, which is lower than in previous years, as is shown in the following table:

1906	15.40
1907	40.93
1908	25.62
1909	12.72
1910	10.98

The annual average death rate per thousand in the cities of Panama, Colon, and the Canal Zone, including both employees and civil population, was 21.05, which is also less than in previous years, the rate for the same month in 1906 being 46.50; for 1907, 47.75; for 1908, 35.12; for 1909, 26.66; and for 1910, 22.86. In calculating according to race, the annual average death rate per thousand from disease among employees for the month was 1.89

for whites and 6.23 for blacks, giving a general average for disease of 5.07. For the same month in 1909 the annual average death rate per thousand from disease among whites was 1.93; among blacks, 7.08, and in 1910, among whites, 1.95; among blacks, 8.91, making a general average for the month in 1909 of 7.89, and in 1910 of 7.21. No case of yellow fever, smallpox, or plague originated on or was brought to the Isthmus during the month.

Christian Science Death.—A young woman living in Fairfield county, Connecticut, died recently after having been attended in childbirth only by a Christian Science "healer." Medical attendance was not allowed until a short time before death. The coroner of the county has ruled that a sincere Christian Scientist can not be held responsible in law for a death; he considers that legal interference is authorized only in cases of possible contagion.

Liners Held at Quarantine.—Two cases of spinal meningitis were found among the 1,478 steerage passengers who arrived in New York on March 30 on the steamship *Venezia* from Mediterranean ports. A case of smallpox was also discovered among the passengers on the steamship *Verona*, which reached New York on March 31 from Italy. All the patients were transferred to Swinburne's Island.

J. Alison Scott Memorial.—The friends of the late Dr. J. Alison Scott, adjunct professor of medicine in the University of Pennsylvania, have raised a fund of $10,000 as a memorial. Of the income from this sum $200 will be available each year to help some worthy third or fourth year medical student in the university finish his course of study. The remainder of the income is to be reinvested until it amounts to a sum sufficient to support some physician in research work.

Coroners' Offices Move.—The Coroners' offices in New York City, which for the past sixteen years have been situated in the Criminal Courts Building, were removed on March 31 to the Ahern Building, on the corner of Lafayette and Franklin streets. The general offices occupy the third floor of the building, the private offices the fourth floor, and the court room the seventh floor.

Dr. Theobald Smith, professor of comparative pathology in the Harvard University Medical School, has been appointed Harvard exchange professor at the University of Berlin for the academic year 1911-1912.

Condemn Exposed Candy.—Acting under special orders from the New York Board of Health, the inspectors of the department on March 29 began an active crusade in the enforcement of Section 46 of the Sanitary Code, which provides for the proper protection of foodstuffs offered for sale. Attention was especially directed to the street candy stands, and large quantities of confectionery were found exposed for sale in an uncovered and unprotected condition. In the district including Broadway from Duane street to the Battery and Wall street, the inspectors condemned and destroyed between 250 and 300 pounds of candy which was found to be in a filthy and evidently contaminated condition.

Vaccination and Smallpox.—During the year 1910 the New York City Department of Health performed a total of 107,533 vaccinations, 25,877 of which were done in the public schools. In not a single one of these cases were there any ill effects which could be traced to the vaccine itself. During the same period only sixteen cases of smallpox occurred in the city. A bill now before the Legislature authorizes the designation of certain public schools as exempt from the compulsory vaccination law, and Commissioner Lederle has expressed his disapproval of such a measure, which would create centers where there would always be a possibility of the development of an epidemic of smallpox. Such a school would be attended by children from a large area, and the occurrence of a single case of the disease among the pupils would be the means of spreading the disease widely. The principle of compulsory vaccination of school children is the basis of the system of protection against smallpox where compulsory vaccination of adults is not in force, and it has proved measurably successful in every country where it has been rigidly applied.

College of Physicians of Philadelphia.—The second of the Weir Mitchell lectures was delivered on March 30 by Dr. Edmund B. Wilson, professor of zoology in Columbia University, on "The Cellular Basis of Heredity."

Anti-Vaccination Protest.—In Montclair, New Jersey, on March 28, over a hundred residents, men and women, held a meeting to protest against the action of the Board of Education in ordering that all children attending the public schools, except those who are exempted by their physicians, must be vaccinated by April 10. A petition appealing against the enforcement of the order will be circulated through the town for signatures. An association to be known under the imposing title of the Anti-Compulsory Vaccination Association of Montclair and Vicinity, was also formed as the result of the meeting.

Dr. Wilfred T. Grenfell, the missionary to Labrador, has received from the Council of the Royal Geographical Society of England the Murchison Bequest for the current year, in recognition of his work and contributions to the knowledge of the people and the resources of the Labrador region.

Charitable Bequests.—The Presbyterian Hospital, New York, receives a bequest of $10,000 under the will of the late Mrs. Benjamin Welles, the income of which is to be used "to brighten the lives" of the nurses and the patients in the general wards.

Plague in Java.—Newspaper reports declare that there has been a serious outbreak of the plague in the southwestern portion of Java. It is stated that 350 cases, of which 224 have proved fatal, have occurred.

Roetheln at Harvard.—Harvard University is suffering from an outbreak of German measles, and nearly forty cases have been under treatment in the Stillman Infirmary.

Russell Sage Institute.—After a meeting of the directors on March 27, the withdrawal of the Russell Sage Institute of Pathology as pathologists of the City Hospital and of the City Home was announced. The cessation of helpful relations and cooperation between the Department of Public Charities and the institute is given as the reason for the step. No statement as to the future work of the institute has been made.

Ambulance Crash.—An automobile ambulance belonging to the Kings County Hospital, Brooklyn, N. Y., collided with an automobile on March 27, the force of the impact ripping three wheels off the ambulance and sending the body of the machine into the window of a grocery store. The two patients in the ambulance were not hurt, but the driver of the automobile sustained several injuries.

In Honor of Drs. C. D. Clawson and G. O. Smith.—On Thursday, March 30, the Schuyler County

Medical Society gave a complimentary dinner at The Glen Springs, Watkins, N. Y., in honor of the fiftieth anniversary of the graduation of Dr. Charles D. Clawson of Montour Falls, and of Dr. Gideon O. Smith of Odessa. Dr. Charles G. Stockton of Buffalo made an address; Dr. Clawson read a paper entitled "Reminiscences of a Student of Fifty Years Ago," and Dr. Smith read a paper entitled "The Recollections of a Young Practitioner Fifty Years Ago"; Judge O. P. Hurd of Watkins made an address upon "The Experiences of a Patient Fifty Years Ago"; Dr. Arthur W. Booth of Elmira read a paraphrase on Kipling's "Road to Mandalay" entitled "The Road to Yesterday"; Dr. Sherman Voorhees, chairman of the Sixth District Branch of the New York State Medical Society, made a few appropriate remarks. Thirty-four members and guests of the Schuyler County Medical Society sat down to the dinner. Dr. Clawson and Dr. Smith were the recipients of hearty congratulations and expressions of the good will of their friends and neighbors.

The Control of Venereal Diseases.—At a recent meeting of the Board of Health of New York City, a resolution was passed expressing the sense of the Board that the early adoption of a comprehensive plan for the sanitary control of venereal diseases is necessary for the protection of public health and called upon the Medical Advisory Board to submit recommendations. It was also resolved to request the municipal authorities to erect a public hospital for such diseases.

State Conventions.—The South Carolina State Medical Association will hold its annual convention in Charleston on April 18, 19, and 20. Dr. Alexander Lambert of New York and Dr. Judson Doland of Philadelphia are among those who will address the meeting.

The annual meeting of the Georgia State Medical Association will be held in Rome on April 19, 20, and 21.

The Nebraska State Medical Association will meet in Omaha on May 2, 3, and 4, and plans are being made for an interesting series of clinics to be held in connection with the meetings.

American Guild of St. Luke.—The New York branch of this society, which is the parent of other branches since formed in Boston, Chicago, and Philadelphia, will hold its next meeting at the Catholic Club, 120 West 59th street, on Thursday evening, April 13, at 8.30 P. M. The subject for general discussion will be "The Proper Teaching of Physiology to the Young." Physicians interested are invited to send their names to Dr. Charles E. Nammack, president of the Guild, or to Dr. James J. Walsh, its secretary.

The Late Dr. Charles H. Lewis.—At a meeting of the Medical Board of St. Vincent's Hospital held April 2, 1911, the following minute was adopted: "We enter in the records of the Board a minute expressive of our deep grief and profound shock, because of the sudden death of Dr. Charles H. Lewis, president of the Medical Board, and a much respected colleague.

"His ever genial companionship and his sincere attention to duty were an inspiration to us all. His keen sense of justice and patient consideration of the shortcomings of his associates were an earnest of an amiable and forgiving nature rarely to be found, and sad, indeed, to lose. The afflicted and the unfortunate of this Institution will long mourn his loss and seek in vain for the degree of aid and comfort so bountifully bestowed by him. Dr. Lewis' career in St. Vincent's Hospital, as interne, chief of staff of Out-Patient Department, and visiting physician, twenty-seven years in all, fitted him completely for the high station in his profession generally accredited to him, and for the fulness of sympathetic spirit so characteristic of his nature. By his death the hospital loses a substantial support, the profession an able and valued member, and the community a good citizen.

"Resolved, That a copy of this minute be published in the Medical Record, *New York Medical Journal*, the *New York Herald*, and *New York Times;* also, that a copy of the same be forwarded to the family of the deceased. Charles E. Nammack, M. D., *Secretary of Board.*"

Obituary Notes.—Dr. Charles Henry Lewis of New York died suddenly on March 31, following a stroke of apoplexy, at the age of 52 years. Dr. Lewis was graduated from Yale University in 1882 and from the Bellevue Hospital Medical College in 1884. He was a clinical lecturer on medicine in the University and Bellevue Hospital Medical College, and attending physician to St. Vincent's and Columbus Hospitals. He was a member of the American Medical Association, the New York State and County Medical Societies, the New York Pathological Society, the Harvey Society, the Society of the Alumni of St. Vincent's Hospital, and the Hospitals Graduates' Club, and a Fellow of the New York Academy of Medicine.

Dr. Warren B. Outten of St. Louis, Mo., a graduate of the Medical Department of Washington University, St. Louis, in 1866, for thirty-six years chief surgeon of the Missouri Pacific Railroad, and more recently consulting surgeon, from 1868 to 1870 professor of anatomy at the St. Louis College of Physicians and Surgeons, and from 1886 to 1901 dean of the Beaumont Hospital Medical College, and a member of the American Medical Association, the Missouri State and St. Louis County Medical Societies, and the American Association of Railway Surgeons, died at his home of pneumonia on March 19, aged 66 years.

Dr. Isaac S. Cramer of Flemington, N. J., a graduate of the College of Physicians and Surgeons, New York, in 1854, and a member of the New Jersey State and Hunterdon County Medical Societies, died at his home on March 26, aged 77 years.

Dr. John W. Van Deusen of Brooklyn, N. Y., a graduate of the Medical Department of New York University in 1884, a member of the New York State and Kings County Medical Societies, and the Brooklyn Medical Society, and attending physician to the Kingston Avenue Hospital, died at his home on March 28, aged 48 years.

Dr. Samson A. Ayo of Thibodaux, La., a graduate of the Medical Department of Tulane University, New Orleans, in 1899, and a member of the American Medical Association and the Louisiana State and Lafourche County Medical Societies, died at his home of typhoid fever on March 11, aged 39 years.

Dr. William C. Karsner died at Chesapeake City, Md., on March 26, at the age of 80 years. He was graduated from Jefferson Medical College in the class of 1853, and he served as assistant surgeon in the United States Army during the Civil War.

Dr. Reuben C. Hoover of Osborn, Ohio, a graduate of the Pennsylvania Medical College, Philadelphia, in 1848, died at his home on March 19, aged 89 years.

Correspondence.

MANCHURIAN TYPHOID AND BRILL'S DISEASE.

To the Editor of the Medical Record:

Sir:—I read with much interest the editorial article in the Medical Record of March 25, under the caption of "Manchurian Typhoid and Brill's Disease." It seems to me that there are so many points of difference between these affections that even clinically they would not be considered the same. The Russians have been able to demonstrate agglutination with "Manchurian typhoid" serum and typhoid group organisms, which would demonstrate a kinship of this disease with typhoidal infections. Thus far no agglutination has been demonstrated of the serum of the disease I described with any typhoidal group bacillus. In fact, I believe that it is now conceded by everyone who has had the opportunity to study these cases that no relationship whatever exists between this disease and any typhoidal infection, using typhoidal in the sense of infection with any typhoid group organisms.

The autopsies on my cases show absolutely normal intestines, no enlarged lymph follicles, no enlarged Peyer's patches, no intestinal hyperemia or ulcerations such as Horinchi found in the Manchurian fever. The clinical differences exist in the eruption which, unlike "Manchurian typhoid," is not abundant at the flexure of the joints, in the permanency of the eruption, which does not fade before the crisis, but remains until the end, and in the non-epidemic character of the disease.

While a motile typhoid-like bacillus has been recovered in the Manchurian disease, the best laboratory methods have failed to reveal any organism in the group of cases described by me.

For all these reasons I believe the diseases to be entirely distinct.

N. E. Brill, M. D.

New York.

HYDROGEN IN THE TREATMENT OF WHOOPING COUGH.

To the Editor of the Medical Record:

Sir:—It has been justly said that many of our important discoveries in science and mechanics have been purely accidental. One of my young patients, Mr. Robert Grosvenor, has accidentally found a useful remedy for whooping cough. Our lack of positive knowledge in this disease is evidenced by the vast array of remedies recommended, most of which we know to be almost if not entirely useless. Mr. Grosvenor was suffering from quite a severe case of pertussis. In the third week while carrying on some experiments in his laboratory hydrogen was generated. At once his trouble was ameliorated; the mucus disappeared, and when the inhalation was repeated a like result followed. He then prepared a flask on the principle of a Woulfe bottle, placed in it zinc previously tested free from arsenic, and poured upon this about 6 per cent. hydrochloric acid. This was used just previous to the cough, or, as I termed it, in the pre-coughing stage. Every time it was successful. His younger sister, whose attack was much more severe, also received immediate relief.

The most interesting result followed in a few days, when Mr. Grosvenor was seized with a severe attack of acute appendicitis, requiring an operation. For three days hydrogen was inhaled whenever there was any accumulation of mucus in the throat, and during these three days there was no cough. By that time all pain from the operation had disappeared. The cough lessened so that further experiments were discontinued.

Mr. Grosvenor's explanation is that the nascent hydrogen acting as a reducing agent on the mucus in the throat liquefies it, permitting its reabsorption, evaporation, or at least its disappearance, with no desire to cough. In its manufacture zinc absolutely free of arsenic must be employed, a fresh preparation each time, and its use continued at each inhalation until no râles are heard or felt in the throat.

I am reporting this discovery, if such it is, that others may try it, especially in those cases where vomiting is so severe that the patient almost starves to death. And I would suggest its use in acute bronchitis and possibly phthisis—in the latter with doubtful effect. It is suggested not as a curative agent, but to relieve by destroying the thick tenacious mucus in these cases.

Henry Ecroyd, M.D.

106 Touro Street, Newport, R. I.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

RENAL CALCULI—SURGERY OF VESCAL CALCULI—CAISSON DISEASE—HEALTH CONFERENCE—MICROBES IN CINEMATOGRAPH—SMALLPOX—OBITUARY.

London, March 17, 1911.

There is a freshness about the views of Dr. Benjamin Moore on renal calculi, as expounded in his Hunterian lecture, which should commend them to physicans and surgeons alike. The many discordant opinions as to the composition and formation of these concretions seem to have been based more on guesswork than serious investigation, or on what Dr. Moore gently calls an "erroneous notion," to wit, that the nature of a calculus can be judged of from its physical appearance—a process like judging a book by its cover. Even when chemical analysis has been resorted to it has mostly been only qualitative, and I think those who have even cursorily looked into the literature of the subject will agree with Dr. Moore that statements based on physical properties are worthless. Dr. Moore proceeded to state the results of twenty-four quantitative analyses of calculi, mostly removed during life by his colleague, Mr. Thelwall Thomas, to whom he expressed his thanks for allowing his surgical trophies to be broken up. Each stone was, first of all, modeled by a skilled modeler, and these models exhibited at the lecture by permission of Mr. Thomas. The results contrast so strongly with the common statements that the lecturer said they refer strictly to these twenty-four calculi and may possibly have to be modified by the results of future additions to the number. But there is nothing in the nature of the cases or of the water in the wide district whence they were obtained to explain the results.

The preponderance of urate calculi so commonly taught receives no support from these analyses; about half of them contained 4 per cent. of uric acid and more would have reacted to a qualitative test and in earlier days would have been set down as uric stones. But it would be absurd so to class a stone with 10 per cent. when it contained 80 per cent. of calcium oxalate. Had urates not been en-

tirely lacking in some stones probably calcium oxalate would never have been discovered as an important constituent. The significance of urates has been greatly exaggerated in various respects including renal calculi. The lecturer pronounced them to be a constituent of only third-rate importance. One cause of the difference between these and former examinations may be that the advance in surgery has led to many stones being removed directly from the kidney or ureter, whereas the earlier specimens were obtained from the post-mortem room or from operations on the bladder. Nearly all the stones reported on in the lecture began as calcium oxalate and as indications for treatment differ according to composition Dr. Moore urged that analysis ought never to be omitted, especially as recurrence is frequent. He said nearly all the textbook directions for diet and treatment of renal lithiasis are based on the supposition of excess of urates and directed to increasing the solubility of these urates. Thus vegetable diet or one poor in proteids is ordered along with alkalies or alkaline waters and closely following one may read that the treatment often fails. No wonder that it should, continued the lecturer, if the two most important and abundant constituents of the concretions are oxalate and phosphate of calcium, for the solubility of both is greatly decreased by alkalies, the oxalate being also increased by vegetable diet. Again, while purins —the progenitors of uric acid—are excluded, milk pudding and ripe cheese are not suspected. But milk proteins load up the body with calcium, the one base always present whether the main bulk of the concretion be oxalate, phosphate or urate; the calcium salt of these three acids is the most insoluble one that exists and this is the reason why it is the invariable one present in renal calculi.

The Lettsomian lectures of the Medical Society of London were delivered this year by Mr. W. F. Haslam, surgeon to the Birmingham General Hospital. He devoted them to a review of the operations for stone in the male bladder. He regarded this as a suitable time for such a review, as it does not seem probable that any great change in practice will take place in the immediate future. In preparation of these lectures Mr. Haslam endeavored to ascertain what was the present practice of other surgeons by addressing inquiries on certain points to those attached to large hospitals. Apart from the definite questions several have remarked that they do not see so many vesical calculi in their hospitals as formerly and this fact is not confined to any particular district. Thus from Norwich, where such stones were once very prevalent, his correspondent says we "scarcely get any cases of stone in the bladder now, though fairly common in the kidney."

Similar reports were furnished from Liverpool, Northampton and many other towns. Why this should be so Mr. Haslam considered an interesting question, but outside the scope of these lectures. The facts certainly corroborate the view of Dr. Moore, expressed in the lectures above mentioned, as to the earlier detection and removal of calculi before they reached the bladder. Another point is referred to incidentally, viz., the question of lithotrity, as to which several surgeons expressed the view that unless there was practice enough to become expert it was better to cut. From this it would seem that the risks attending crushing are fully appreciated by those who have the opportunity of doing it frequently.

With regard to the questions proposed by Mr. Haslam, the first was "What operation do you usually do before puberty?" To this 221 surgeons replied and of those 144 did suprapubic lithotomy, 7 say lithotrity, and 9 others the same, "if possible"; others refer to size of stone and qualifying circumstances. Clearly the suprapubic operation is the one of preference in children.

To the second question, "What operation in males after puberty with no evidence of prostatic enlargement?" there were 240 replies. Of these 116 were suprapubic, 29 lithotrity, 28 this "as a rule," and 48 this "for small stones, suprapubic for others." Other circumstances are mentioned and classified by Mr. Haslam, who concludes that surgeons are prepared to consider crushing in the adult more frequently than in boys and the number who do the suprapubic is in excess of those who crush, and many of the latter reserve it for small stones.

The third question, as to treatment when there is enlarged prostate, elicited 224 replies. Of these 202 said suprapubic; which is therefore the method adopted by almost all surgeons.

The fourth question dealt with the treatment of the wound of suprapubic lithotomy, as to which 230 replied. Of these 33 said complete suture of the bladder and of the abdominal wall without drainage, the urine being normal; 71 said complete suture of bladder and suture of greater part of abdominal wall with drainage, either by a tube or by gauze above the pubes; 9 said the same with, in addition, a catheter left in; 5 were for complete suture of bladder and wall without suprapubic drainage but with catheter left in; 1 the same with catheter passed at regular intervals. Partial suture of bladder and wall was advised with drainage, entirely by a tube, by 9; by tube for a time and then by some apparatus, 5; by catheter, 1; drainage at once by apparatus, 1. No suture of either bladder or wall and drainage advised, by tube entirely, 42; by apparatus, 18; by tube for a time and then apparatus, 24; by tube and catheter, 1; by pads only, 2; suture of bladder to wall and drainage by tube advised by 4; by apparatus, 1; without either, 1; perineal drainage, 1; no sutures nor drainage, 1. On these figures Mr. Haslam said that evidently few surgeons venture to sew up the bladder and close the abdominal wound without some form of drainage, though many will close the bladder and drain it. More than half prefer either partial drainage or none at all.

Dr. Leonard E. Hill, in an elaborate paper on caisson disease, lately communicated to the Royal Society of Arts an account of a diving dress he had designed for men engaged in caisson works, exploration of flooded mines, tunnels, etc. The dress is self contained, filled with cylinders containing 50 per cent. of oxygen, a caustic soda chamber to be carried on the back of the diver and an injector on the inlet of the helmet to purify the air. The oxygen supply lasted an hour, no life line or air pipe was carried. There was no risk at depths of 70 or 80 feet. As to the danger of too rapid decompression he found that he could restore animals on the point of death by quickly recompressing to the former pressure. Some cases reported to him looked as if men had been raised from the dead. He suggested that caisson works run at dangerous pressures should be provided with barracks in which the men should stay after a shift so that they would be at once recompressed should there occur the least sign of illness. His experience showed that fat

men should be excluded from caisson work and the less fat food eaten by men at that work the better.

A conference of medical officers of health was held at the Local Government Board to consider further preventive measures. The president was present most of the time and an official statement says he has summarized some of the main points discussed. These related to notification, hospital accommodation, education as to infection, disinfection, and the question of excluding children under five from school attendance during epidemic periods or at other times. Also the need for regulating private (including Sunday) schools.

The National Health Society has instituted a series of lectures in memory of the late Lady Priestley and Sir E. Ray Lankester has been good enough to open them, discoursing on "Living Microbes." He said microscopists had long been anxious to exhibit groups of them to large audiences, but to get very minute ones on the screen seemed to be almost hopeless. But now a method has been discovered which with a lantern and instantaneous photographs enabled microbes to be seen as though one were bending over a microscope. The microbes were magnified about 50,000 times. By this method and a cinematograph he proceeded to show a large number of interesting specimens. The shape, movements, and other characteristics of various microbes were described and clearly exhibited. Sir A. Wright is to follow with the next lecture this afternoon.

Dr. Thomas, medical health officer for Stepney, reporting yesterday on the smallpox outbreak, said he did not expect further contact cases. As to vaccination he said of the eight children under eight years of age three were and five were not vaccinated. The three had the disease in very mild form. Of the five unprotected four are dead. Of fifteen cases between eight and thirty years three were unvaccinated and one of them died, twelve vaccinated in infancy. Between thirty and sixty years, thirteen vaccinated in infancy, only two died, both over forty. Of three cases over sixty all were supposed to have been vaccinated in infancy. One aged eighty-four died, whether vaccinated doubtful. Last night no further notifications had been made. On Wednesday at midnight forty-six cases remained under treatment in the hospitals, two having been discharged during the day.

Dr. Andrew Smart, consulting physician to the Royal Infirmary, Edinburgh, died on the 8th inst. in his eighty-seventh year. He held the chair of clinical medicine at the infirmary for about fifteen years. In his early days in a report on rinderpest he described the organism of that disease. He retired some years ago. In 1883 his work on Germs, Dust and Disease appeared. He was the author of a number of practical papers on such subjects as diet and drugs, on elimination, cardiac murmurs, respiratory neuroses, etc. He had been president of the Royal Edinburgh Medical Society.

OUR LETTER FROM PARIS.

(From Our Regular Correspondent.)

ANTITYPHOID VACCINATION—REVOLVER BALL IN THE GALL-BLADDER—URETERAL CALCULUS—RUPTURE OF THE PENIS—PROSTATIC HYPERTROPHY—NECROLOGY.

PARIS, March 25, 1911.

AFTER a very long series of discussions on antityphoid vaccination the Academy of Medicine adopted the following conclusions from the report of Vincent, which they formulated thus: The facultative employment of antityphoid vaccination should be recommended as a rational and practical means of lessening the number and gravity of cases of typhoid fever in France and the colonies. This recommendation is addressed to all persons whose profession, their usual and accidental conditions of food or life, and their daily relations with patients or carriers of germs expose them to the contagion, direct or indirect, of the typhoid bacillus.

Surgical Society.—At the Surgical Society Riche reported the case of a man of 26 years of age, who received a bullet from a revolver in the right hypochondrium. The orifice of entrance was in the eighth intercostal space, 2 cm. outside of the nipple line. Riche operated at once by a vertical incision 10 cm. in length along the external border of the rectus muscle, and found that there was bile in the peritoneal cavity. The removal of the gall-bladder was done. When this had been taken away the ball was found in the cystic duct, having penetrated by a small opening plainly visible on its interal face. After several days of severe illness the patient recovered entirely and left the hospital six weeks afterward entirely cured.

An interesting observation of calculus of the ureter treated by George Luys was reported by Legueu to the Surgical Society. The patient was a man 42 years of age, who showed undoubted signs of calculus obliteration of the left ureter. A No. 6 ureteral sound was placed in the left ureter; it was arrested after entering 20 cm; it encountered an obstacle, and when it was pushed a flow of pus appeared between the sound and the ureteral wall. Radiography showed a calculus of the left ureter situated near the transverse process of the fourth lumbar vertebra. As the left kidney was in a condition of complete retention and the urinary secretion of the other kidney diminished in an alarming manner, Luys first made a nephrotomy of the left kidney. Some days later, under the influence of lavage of the pelvis of the kidney, the temperature fell, the left kidney began to secrete, and the general condition improved at once. Fifteen days later Luys performed left ureterolithotomy, which permitted of the extraction of a calculus with fragments of the ureteral mucosa surrounding a stone which weighed 50 grams. The operative results were very simple, but the urine of the left kidney continued to come almost exclusively from the incision of the nephrotomy which had been performed. To prevent this Luys placed with his direct vision cystoscope a large No. 12 sound in the left ureter. The same day of this application the fistula of the left kidney closed and all the urine issued from the corresponding ureteral sound. The patient recovered without complications and was able to take up his usual occupation. But six months later a new obliteration of the left ureter occurred, necessitating a new operation similar to the first. A new ureterolithomy was done, permitting the extraction of a second calculus of the same form as the former one but smaller. This new operation was followed by good results and the patient was completely cured. Recurrence of calculus of the ureters is rare and one only has been previously reported.

Alivazatos presented an observation of rupture of the penis, reported by Legueu, who treated a man of 30 years, who one day, after masturbating, all at once felt a sharp pain, and at the same time heard a sound like the breaking of a glass rod. A con-

siderable hematoma was produced and a very abundant hemorrhagic extravasation was observed which infiltrated through the ruptured fascia of the penis into the surrounding cellular tissue, and reached the scrotum and hypogastric region. To arrest the advance of the hematoma an operation was performed in the course of which it was found that there was a complete rupture of the two corpora cavernosa, which were bleeding; the corpus spongiosum was hardly touched. Three catgut sutures were introduced to reunite the ruptured bodies and stop the hemorrhage. Union by first intention took place at the end of ten days; about the twentieth day erections were normal and complete.

Cuneo presented an interesting study of prostatic hypertrophy which was reported by Hartmann. Prostatic hypertrophy consists of an adenomatous new formation exclusively at the expense of the periureteral glands. The glandular apparatus proper takes no part in the new formation, which explains the elongation of the canal in the course of prostatic hypertrophy, its saggital increase through the growth of the glands situated along the walls, the eccentric action of the sphincter, the prominence of the neck and the formation of the base, and the absence of involvement of the ejaculatory ducts. These anatomopathological facts show that transvesical prostatectomy by enucleation is the operation rationally indicated for adenomatous formations in the prostate situated below the verumontanum, and the simplest way of removing them is to make a transvesical enucleation of the glands. Cuneo then gave the results that he had obtained by the performance of the lateral perineal prostatectomy of Wilms. This procedure consists in approaching the prostate by an incision parallel to the ischiopubic branch. The subpubic perineal aponeurosis is cut and dissociated with the handle of the bistouri and the finger, up to the urogenital diaphragm. On the inside of the ureter, held by a sound, and on the projection made by the prostate, the diaphragm is torn, and through this breach the prostatic lobes are enucleated. The operative results of Wilm's operation are not satisfactory for if it is distinguished by the simplicity of its immediate operative results, it does not seem that it should always be substituted for the prostatectomies heretofore used. As Legueu has said, the Wilms' operation seems to include all the disadvantages of the perineal route with none of its advantages. From this discussion the conclusions are that everyone seems to be in accord to-day in the belief that the operation of transvesical prostatectomy by the method of Freyer is much better than this, and is the only rational therapeutic procedure to apply to the treatment of prostatic hypertrophy.

Dr. Kelsch, who died at the age of 70 years, was Medical Inspector of the Army, Commander of the Legion of Honor, and Director of the Institute for Vaccines of the Academy. Born in Alsace, he studied at Strasbourg. He was named acrégé in Epidemiology at Val de Grace, then professor of the Faculty of Medicine of Lille, where he directed pathological anatomy. It was in this chair that he made his interesting anatomopathological researches on the liver and kidneys. In 1882 he returned to Val de Grace as professor of epidemiology. It was in this professorship that he became famous for his studies of epidemic diseases and malarial affections, which were very severe in Algeria where he stayed for a long time. The very important studies of paludism, of malarial anemia, and nephritis constitute an important advance in the history of these diseases. No one can forget his works on dysentery, diarrhea of Cochin China, and dysenteric abscess of the liver. In 1893 Kelsch was elected member of the Academy of Medicine, where he took an important place and presented many papers.

OUR LETTER FROM HAVANA.

(From Our Regular Correspondent.)

MEDICAL PRESS CONGRESS—CUBAN NATIONAL MEDICAL CONGRESS—BERIBERI—HEALTH CONDITIONS.

Havana, March 22, 1911.

A CONGRESS of the medical press was held for the first time in Cuba at Havana's Academy of Sciences on February 22-23. It was organized chiefly by the efforts of Dr. Santos Fernandez, who acted as president. The rest of the executive committee were Drs. Bustamante, Presno, Nunez, and Casuso, vice-presidents; F. M. Fernandez, Arteaga, Casariego, and Valdes, secretaries. The congress was attended by forty members and twenty-two papers were read. Among the more interesting were those of Santos Fernandez, "Difference between the Lay and the Medical Press in Cuba"; Barnet, "Obstacles Met with by the Medical Press in Cuba"; Curguejo, "Relations between the Medical Papers and the Pharmacists"; Segin, "Laryngology and the Cuban Medical Press"; Le Roy, "History of the Medical Press in Cuba"; F. M. Fernandez, "Ophthalmology and Its History in Cuba"; Garcia Rijo, "Medical Press and Medical Association in the Rural Districts."

In the last session several motions were carried. The most important were the following: (1) To select the committee for the organization of the next congress of the medical press. (2) To organize the Cuban Association of the Medical Press. (3) To invite the directors of the several hospitals to study the advantages or dangers of the various drugs or serums that are being investigated.

The Second Cuban National Medical Congress was held in Havana from February 24 to 28, with over 300 members. The congress was divided into four sections, with eight subsections, and over 100 papers were read. The official subjects treated were pulmonary tuberculosis, cesarean section, the transmission of insanity; the administration of bacterial vaccines was also discussed and also tetanus. On the last day the following executive committee was elected almost unanimously: *Honorary Presidents*, the Secretary of Public Health, the President of the Academy of Sciences, the Dean of the Medical School, and President of the Sociedad de Estudios Clinicos. The executive committee was elected as follows: *President*, Dr. Gabriel Casuso; *Vice-Presidents*, Drs. Fernando Mendez Capote, R. Garcia Rijo, J. Ortiz, José Guell, F. Sirvén, and M. Weiss; *General Secretary*, Dr. Francisco M. Fernandez; *Vice-Secretaries*, R. Nogueiras, A. Barrera, R. Perez Vento, and J. de Cubas; *Treasurer*, Dr. G. Fernandez Abren. On the same day the following motions were carried: To create a committee for medical defense. To publish together all papers read at both congresses. To establish free dental service in the public schools. To limit the number of drug stores to be opened. To hold the third congress in the fall of 1914.

Three cases of beriberi have been reported among the inmates of a large prison in Santa Clara. The cases have been investigated and diagnosis confirmed by Dr. Marie Lebredo and the epidemic has been

checked. The diet of the convicts had consisted of rice (which has been supposed to be the cause and therefore has been suppressed), potatoes, beans, and meat.

Sanitary conditions in Cuba are exceedingly good. No cases of yellow fever or of smallpox have appeared during 1910 and none so far in 1911. Malarial fever is chiefly confined to Oriente Province and in no alarming proportions. A quarantine has been established against the Canary Islands on account of the bubonic plague and our sanitary authorities are confident that neither plague nor cholera can enter Cuba, the proper measures having been taken.

Popular Fallacies About Insanity. H. R. Stedman.
Address of the President Before the New England Pediatric Society. J. L. Morse.
When Shall We Remove Tonsils and What Type of Operation Shall We Do? E. A. Crockett.
Secondary Efforts to Hasten Healing After Mastoidectomy. H. O. Reik.
The Alleged Increase of Nervous Diseases. P. Knapp.
An Infection of the Bladder with Penicillium Glaucum. A. L. Chute.

Popular Fallacies About Insanity.—H. R. Stedman believes that it is a great mistake to draw the conclusion that the increase in the insane population of the hospitals necessarily indicates that the disease insanity is itself increasing.

Address Before Pediatric Society.—J. L. Morse notes that a short paper is always more interesting and more instructive than a long one. There are often many details which should be published, but which are tiresome and are better omitted when a paper is presented before a society. Another suggestion is that papers are always more impressive and more interesting when they are spoken than when they are read.

Removal of Tonsils.—E. A. Crockett states that in children one should remove the tonsils in all cases where the child presents large non-adherent tonsils largely filling the cavity of the pharynx, because of the obstruction in breathing that such cases present and of their possible influence upon nutrition, and to secure the proper formation of the jaw at the period of second dentition. One should enucleate the tonsil in all cases associated with enlarged glands in the neck, and in all cases of articular rheumatism where the tonsil is probably an etiological factor. These operations should be, as a rule, performed in a quiescent period, especially in the case of rheumatism, when the nervous shock and the additional sepsis should both be avoided in the acute stage. The existence of endocarditis in a more or less chronic state need not necessarily be regarded as a contraindication for operation. The tonsils should be thoroughly enucleated in all cases of repeated peritonsillar abscess. Conversely, the tonsils should not be removed where they are of moderate size, projecting not over a quarter of an inch beyond the anterior and posterior pillars.

Healing After Mastoidectomy.—H. O. Reik concludes that mastoid fistulæ do not ordinarily require elaborate plastic operations, with the formation and transposition of skin flaps, but may be closed by repeating what was or should have been done at the time of the original mastoid operation, and primary union will almost surely follow the closure of such wounds. If one fears to attempt primary union after mastoidectomy, or if attempts in that direction are attended by failure, this method of secondary closure offers an alternative or a corrective. One may pack the wound at the time of operation in the ordinary way, and at some later date, when sure that the local infection has been controlled, if not eliminated, and that the patient is satisfactorily convalescing, one can recleanse and close the wound with every assurance of safety and speedy healing. The advantages to be gained are: The saving of at least a month in the time required for healing; the saving of much discomfort for the patient and trouble for the surgeon; and the substitution of a small linear scar for a rather unsightly one with more or less depression.

Alleged Increase of Nervous Diseases.—P. C. Knapp in studying the records of the out-patients' service of the Boston City Hospital for the period between 1877 and 1908, notes that in spite of the enormous increase in the total number of patients treated, there was a decrease in the percentage of nervous patients to the total number.

Infection of Bladder with Penicillium Glaucum.—A. L. Chute reports a case of this condition occurring in a woman of sixty-one, who had noted for some time white masses floating on the surface of the urine. For three years she suffered with the symptoms of an acute cystitis. Examination of the bladder showed brilliant white masses at its vertex. These were found to consist of a growth of *Penicillium glaucum*. Recovery followed suprapubic cystotomy, light rubbing of the bladder interior with gauze, and subsequent drainage.

Nonsuppurative Osteomyelitis. J. G. Stewart.
Bismuth in Gastric Therapy. A. Goldman.
Picric Acid—a Retrospect. A. Ehrenfried.
Vaccine Therapy. C. T. Russell.

Prostitution and Venereal Diseases in New York City.—F. Bierhoff states that prostitution cannot be stamped out. In dealing with this problem the first two steps of importance must be greater care in the supervision of immigration and stricter requirements for the franchise of citizenship. Older children should be taught the anatomy, physiology, and hygiene of sex, and the dangers of venereal diseases. The lack of playgrounds plays an important part in the corruption of the children. Girls should be taught to become good housewives and to take a pride in their homes. The author cannot subscribe to the view that the majority of men who have relations with prostitutes do so only because of depravity or viciousness, but rather because it is the only substitute for matrimony within their reach. The woman who has been a successful public prostitute—that is, one who has been able to make enough money to buy her the comforts and the finery and drink which she wants, is rarely won permanently from that life. One must try to make it clear to the parents and the family that the surest way to bring about the complete downfall of a mistaken girl is to close the door of her home against her. No efforts, then, should be spared, in attempting to reach the beginners in prostitution, and to make clear to them the wrong and the dangers of the life upon which they are entering, and the poor outlook, as a business proposition, of the prostitute's career.

Anorectal Diseases.—S. G. Gant states that most minor anorectal operations can be painlessly performed under local anesthesia induced by sterile water or one-eighth of one per cent. eucaine solution. In the treatment of internal hemorrhoids the operation of ligature is the oldest, most generally used, as reliable as any, rarely followed or accompanied by hemorrhage or complications, and the results are all that could be desired. In the treatment of fissure, incision or division of the sphincter is

the simplest and best procedure, causes the least postoperative pain, and obtains the quickest results.

Intestinal Parasites.—R. C. Rosenberger made an investigation to determine to what extent infestation with intestinal parasites was prevalent in the Philadelphia General Hospital. Of the total number of specimens examined, 1,280 stools, 552 were fluid, 413 were semi-fluid, and 315 were well formed or solid stools. Of the fluid stools, 92 contained ova or parasites, of which two-thirds were cercomonas. Of the semi-fluid stools, 53 contained ova or parasites, with a similar preponderance of cercomonas, which preponderance was also found in the case of the 25 solid stools that contained ova or parasites.

Zinc Oxide in Face Powder.—S. S. Cohen notes in connection with the black-line test for vasomotor ataxia, produced by drawing a silver coin across the cheek, that from time to time in testing the faces of women for this reaction, he has observed a very deep black line. This has been found to be due to the reaction between the silver of the coin and zinc oxide contained in face powder.

Mastoid Dressings.—E. Amberg describes a few devices in mastoid dressings that he has found very useful.

Nonsuppurative Osteomyelitis.—J. C. Stewart states that three distinct clinical conditions may be classed under the title of nonsuppurative osteomyelitis: (1) Cases of ordinary osteomyelitis in which, owing to the nonvirulence of the invading germ or to unknown conditions increasing the resistance of the individual, no necrosis is caused. In such cases there is no pus, no sequestrum, but instead, in a certain number, marked irritative reaction is set up and there is great overproduction of bony tissue, resulting in a thickened, dense, and painful enlargement of the bone attacked. These cases are quite common, regularly recognized, and properly treated. (2) Cases of injury, generally clinically fracture, where a small piece of bone is entirely separated and dies, forming about it a closed cavity of dense new bone in which it lies until absorbed, but without suppuration. (3) The one to which the author especially calls attention differs entirely from the two previous classes by having no notable beginning but an insidious onset, although a febrile illness, and a slight injury respectively antedated by two years the culmination of the disease by surgical interference. The disease is essentially chronic, but progressive and regularly misdiagnosticated and treated as rheumatism.

Bismuth in Gastric Therapy.—A. Goldman analyzes 100 cases of gastric disorder in which bismuth was used in doses of one-half to one dram one-half hour before eating, in half a glass of water; also in combination with magnesia usta and sodium bicarbonate. It is concluded that bismuth given in doses large enough acts mechanically, forming a coating on the mucous lining as well as reducing the acidity of stomach contents markedly, differing from alkalies in that it does not stimulate the flow of gastric juice. Given in cases of gastrosuccorrhea it retards secretion and coats the stomach, relieving it of the gnawing pain and doing away with nausea. It acts much more powerfully on a fasting stomach.

Picric Acid.—A. Ehrenfried presents an historical review of the employment of picric acid in medicine and surgery. Its application in the latter was suggested by its common use in tanning leather, in preserving specimens for microscopical examination, and in its power of coagulating albumin. After Chévon in 1876 recommended its use on wounds and ulcers as a means of encouraging cicatrization, arresting fermentation, and drying up morbid secretions, Thiéry ten years later reported excellent results in ulcers, granulating wounds, excoriations, various skin diseases, urethritis, and particularly burns. Other observers have since reported good results following the use of picric acid in eczema, erythema, artificial dermatitis, impetigo contagiosa, erysipelas, lupus, gonorrhea, cracked nipples, mucous patches, and fissure paronychia, synovial membranes.

Vaccines in Gonorrheal Rheumatism.—C. T. Russell notes that in gonorrheal rheumatism the use of vaccine to a great extent prevents the development of pus in the synovical membranes.

Sodium Cacodylate in Tertiary Syphilis: Report of a Case. L. W. Crigler.

Control of Uterine and Adnexal Pain.—C. A. L. Reed concludes that visceral pain, so far as the abdomen, pelvis, and thorax are concerned, is expressed chiefly but not exclusively in the autonomic algetic areas in the protective walls covering the respective viscera, such algetic areas corresponding in extent with the peripheral distribution of the autonomic nerves coincidently with the peripheral distribution of the respective spinal nerves in the muscles and subserous connective tissue. These distributions can be generally determined clinically by determining the area of parietal hyperalgesia. The pain itself, consisting chiefly of hyperexcitation of muscle irritability, can be partially and, as a rule, entirely, inhibited by inhibiting the muscle sensibility in the hyperalgetic areas. The same principle applies to the peripheral control of pain originating in the parturient uterus, with the difference that the infiltration of succeeding muscle zones must be practised with the corresponding advance of the delivery.

Open Treatment of Fractures.—S. D. Van Meter concludes that the open treatment of fractures insures practically anatomic reduction. One has overestimated the danger of making a compound out of a simple fracture. The Lane plate is the simplest and most efficient fixation device yet designed. It insures immediate immobilization, which in turn means rapid repair and reduction of pain to a minimum. Its application is easier and requires less mutilation and smaller incision than the use of wire. It is a great aid in the management of compound infected fractures. Direct mechanical fixation of fractures greatly simplifies after treatment. The *x*-ray has shaken one's confidence in manual reduction and will force one to more accurate methods.

Tonsillectomy.—G. Sluder describes a method of tonsillectomy which he has not seen heretofore published. The essential and distinctive feature of this method is the fact that it moves the tonsil completely out of its normal bed, forward and upward, and utilizes one of the anatomic markings of the lower jaw as a vantage point for forcing it through the aperture of the guillotine.

Lipomatosis of Lower Extremities.—W. R. MacAusland and B. E. Wood report a case of lipomatosis of the feet and legs which seemed to have originated before birth and rapidly progressed till it became a serious embarrassment. Several operations were performed, including amputation of the toes at six months of age and later

conservative operations for the removal of the fatty growths. These, however, did not suffice and amputation of the left leg was performed at the age of twelve. The patient now walks well with crutches and the right foot has ceased to grow.

Angiosarcoma of Liver.—J. Bondy states that the chief features in the case, which is reported on account of its rarity and the difficulty of making an accurate diagnosis, are: first, the early period of life at which the tumor started (possibly before birth); second, the rapid increase in abdominal girth; and the paucity of the symptoms until just before death, at the age of three and one-half months.

Proctolysis Apparatus.—P. Nicholson describes a simplified apparatus in which the salt solution is heated by means of two hot water bags, placed one on each side of the rubber tubing.

Application of Plaster Jacket.—P. W. Roberts describes a new method of applying the plaster jacket in hyperextension. The apparatus consists of a jack and sling by means of which the patient is supported in the horizontal position while the plaster jacket is being applied. It is said to compare favorably with the usual method of upright suspension. By allowing the terminal parts of the spine to fall automatically and abruptly away from a narrow point of support it secures the greatest degree of hyperextension obtainable in any given case within the limits of safety. Further advantages over the upright method are greater steadiness of the patient, greater comfort of the patient, an easier attitude for the operator, less splashing of plaster, greater convenience in the application of jackets away from the plaster room—that is, in the home or hospital wards—the requirement of fewer assistants, and the natural assumption of a better mechanical position for the diseased spine.

Rupture of Kidney.—F. G. Connell states that owing to the rapid recent increase in the number of reported cases there is reason to believe that subparietal rupture of the kidney is more frequent than the literature would lead one to believe. Shock, injury to other organs, and external evidence of trauma are frequently absent. A history of an abdominal contusion, followed by rigidity and hematuria, is sufficient warrant for an exposure of the organ. Slight lesions and complete rupture of the kidney cannot be differentiated by clinical signs or symptoms. Proof that there is an absence of serious rupture is called for before instituting the socalled expectant treatment. Nephrectomy should be reserved for very extensive disintegration of the organ. Conservative treatment, preferably by suture, is indicated in the majority of cases.

Adenoid and Tonsil Operation.—J. E. Rhodes states that one of the most important steps in the operation of tonsillectomy is the adequate enucleation of the tonsil.

Preservation of Anatomic Dissections.—E. Souchon describes his method of preserving anatomic dissections with permanent color of muscles, vessels, and organs.

Typhoid Meningitis.—V. C. David and F. A. Speik conclude that typhoid bacilli are not found in the cerebrospinal fluid in uncomplicated cases of typhoid fever. Typhoid patients suffering the ordinary nervous manifestations, such as delirium, involuntary discharges, carphologia, and severe headache, are not benefited by withdrawal of cerebrospinal fluid, although the fluid may be under increased tension. In typhoid patients showing classical symptoms of meningitis the cerebrospinal fluid may be sterile, but lumbar puncture and withdrawal of fluid have improved the clinical condition in a striking way in some cases. When typhoid fever patients show meningeal symptoms, such as rigidity of the neck, Kernig's sign, convulsions, strabismus, or irregularity of the pupils, lumbar puncture should always be done, and the fluid obtained examined bacteriologically and microscopically.

Ionic Surgery.—G. B. Massey reports a case of extensive vulvar epithelioma and one of recurrent growth of the meatus urinarius treated by ionic surgery.

Gallstone Disease.—C. C. Coleman discusses the diagnosis of this condition in the early stages. In these one notes mild gastric disorder with irregular attacks of indigestion coming on suddenly, with gas formation and feeling of epigastric constriction or tightness, chilliness, belching, regurgitation, and vomiting. In the second stage there may be dull or severe pain under the right costal arch which may be aggravated by food, sudden exertion, or deep inspiration. These attacks are frequently evanescent in type and followed by periods of good health. Unless careful chest examination is made there may be a diagnosis of pleurisy. In making a diagnosis of gallstone disease the etiological possibilities should be investigated. It is known that it often follows typhoid and pregnancy, and probably any infectious disease that produces toxins that may irritate the gastrointestinal tract may be a cause of cholecystitis.

Vaccination in Japan.—S. Kitasato presents tables showing marked contrasts in the death rate between the vaccinated and the unvaccinated population.

Standard and Authority.—C. E. Vincent states that slowly and grudgingly the technical expert, the railway and mining engineer, the architect, and of late the agricultural specialist have been given recognition by the many. But against doctors, especially experts in insanity, sanitarians, university professors, and others who arrogate to themselves special knowledge that is not easily tested in tangible, material ways the American democracy still directs a large measure of incredulity and derision. And this, too, in spite of constant resort to physicians and personal confidence in them in individual cases. It is the difference between "my doctor" and the "doctors." Then, too, for obvious reasons the antagonism is much more marked toward bacteriologists and sanitarians than toward physicians in private practice.

Salvarsan in Pellagra.—C. M. Nice, J. S. McLester and G. Torrance report early and material improvement of symptoms in three typical cases of pellagra following the administration of salvarsan.

Sodium Cacodylate.—L. W. Crigler reports a case of tertiary syphilis markedly benefited by the administration of sodium cacodylate.

The Lancet.

The Iodine Method of Sterilizing the Skin. P. Turner and H. C. Catto.
An Egyptian Holy Man. C. G. Seligmann.

Ankylostoma Infection.—A. E. Boycott states that practically all tropical countries are permeated with the worm, and in places where the conditions for its propagation are not unfavorable it may reduce four-fifths of the population to a continual state of chronic ill-health which is only terminated by their premature decease, commonly from some secondary affection. Under circumstances where the prevailing conditions are more or less inhibitory, though most people may be infected, yet in relatively few is the dose of parasite so big or the resistance of the host so small that any demonstrable illness is produced. An individual in whose bowels ankylostoma is living and whose tissues are shown to be reacting to its presence by changes in the bone marrow may be said to be infected with ankylostoma in the true sense. But if there are no subjective or objective signs of illness

one cannot reasonably say that he is suffering from the disease of ankylostomiasis. It is necessary, therefore, to distinguish between cases of ankylostoma infection without illness and cases of ankylostomiasis as sharply as the fact that the one must grade imperceptibly into the other will allow.

Anthropology of Ancient British Races.—A. Keith discusses this subject on the basis of the human remains found in the upper (100 feet) gravel terrace of the Thames Valley, at Galley Hill.

Salvarsan.—J. McIntosh and P. Fredes conclude that on the average, if not invariably, salvarsan is far superior to mercury in the symptomatic treatment of syphilis. It is certain in the earlier stages of syphilis, and probable in the later, that courses of salvarsan, applied at properly ascertained times, will prevent the onset of symptoms with far less inconvenience and effect upon the general health than mercury.

Salvarsan.—T. W. Gibbard and L. W. Harrson conclude that salvarsan has a very marked and rapid effect on the clinical manifestations of syphilis in most cases.

Diagnosis of Gastric Cancer.—I. W. Hall and G. S. Williamson state that Neubauer and Fischer have proposed a laboratory test for the further assistance of the clinician in his diagnosis of cancer of the stomach. It consists of the action of gastric contents upon a polypeptide. From several quarters certain criticisms have emanated, and the authors themselves are not disposed to agree entirely with the basis upon which the reaction rests, nor to regard it as specific. In spite of this, however, in connection with an investigation upon the peptide-splitting action of pathological fluids, the test has, in their hands, yielded results suggesting an advocacy for that extended use which alone can determine its permanent utility.

Iodine in Skin Sterilization.—P. Turner and H. C. Catto have found that the iodine method of sterilizing the skin is at least as effective as the older and more troublesome method of preparation.

An Egyptian Holy Man.—C. G. Seligmann describes the attacks of ecstasy occurring in an Egyptian and hopes that his example may encourage observers among native races to study and describe the facts of all instances of the state, or states, which are commonly grouped under the titles of "ecstasy," "possession," and "shamanism," for there is at least *primâ-facie* evidence suggesting that these three states in certain cases are due to "depersonalisation" or to "multiple personality," and are in many ways comparable with the examples studied and recorded by alienists and psychologists.

The Curative Effect of Salvarsan in Frambesia. H. Alston.

Aphasia.—R. Sauneby states that it is difficult to see how it is possible to escape from the amount of evidence brought forward to show that destruction of the third frontal convolution, even on both sides, does not cause aphasia; but almost equally cogent, and even more abundant, is the evidence that aphasia occurs in cases where this convolution is intact. The usual answer in this evidence is that while it may appear intact, it is not so really; but Marie has lately published three cases of this kind in which the convolution was examined microscopically by serial sections without any lesion being discovered. The only rejoinder that the supporter of Broca can make is that the lesion is functional in character, and reveals itself by no changes which can be detected by present means of research. But those who make this assertion must bear the onus of proof, and it is not easy to produce evidence in its favor. If the convolution of Broca is the seat of the faculty of language its destruction should be invariably followed by loss or impairment of that faculty; further, when there is loss or impairment of the faculty of language this convolution should show always some demonstrable change; if neither of these relations exist, then the only possible verdict must be that the existence of the supposed relation is not proved.

Congenital Word-Blindness.—J. Hinshelwood states that pure congenital word-blindness, which is a local affection of a limited cerebral area, can always be overcome by perseverance and proper methods of education, and herein lies the great importance of the recognition at an early period of the true character of such cases.

Poliomyelitis in Bristol.—G. Parker reports an outbreak of poliomyelitis, involving thirty-seven cases, in Bristol, from June, 1909, to January, 1910.

Etiology of Poliomyelitis.—A. E. Vipond notes the following similarity between typhoid fever and poliomyelitis: Both diseases occur in the late summer or fall months. As soon as the cold weather commences both, to a great extent, become extinct. During the late summer and fall months of 1909, while there was a severe epidemic of typhoid fever in Montreal among the adults and young people, at the same time there was an epidemic of poliomyelitis among the young children and babies. Diarrhea is just as common a sympton in poliomyelitis as in typhoid fever. The incubation period of one is practically the same as that of the other. This has been proved by Flexner to be thirteen days experimentally, and by Holt to be ten days clinically. Both diseases are prevalent in large cities and small towns at the same time where and when the cause of typhoid fever is traceable to the water and milk supply; while on the other hand, where the supply of water and milk is pure both of these diseases are less frequent. It is practically the same degree of contagion. These observations led the author to believe that the microorganism of poliomyelitis might be of the same character as the bacillus of typhoid fever. Upon examination of the blood in cases suffering from poliomyelitis, the author found the Widal reaction present as in typhoid fever, proving possibly that the disease is from the same source and cause, and that the germ of the one is allied to that of the other; further, he does not hesitate to make the assertion that the precautions necessary to prevent typhoid fever will also have the same effect in arresting the spread of poliomyelitis. He has obtained the Widal reaction in six cases of the blood examination out of a total of sixteen cases.

Gastric Origin of Angina Pectoris.—H. W. Verdon reports a case in which the seizures of pain might be explained as being the result of pressure from a tense gastro-esophageal atmosphere transmitted through the esophageal wall and impinging upon the fibers of the plexus gulæ.

Cane Sugar in Heart Disease.—A. Goulston notes the beneficial effect of dextrose on mammalian heart muscle, and that the good effect of taking cane sugar to improve the nutrition of the musculature of the heart has been quite in accordance with what was to be expected from what is known of the physiology of the subject. The author reports a few cases illustrating the clinical value of this mode of treatment of certain forms of heart trouble.

Mechano-Therapeutics in Chronic Constipation.—E. F. Cyriax, in considering the pathology of chronic constipation from the mechano-therapeutic point of view, notes the following three features: Diminution in the expulsive

power of the intestines; diminution in the function of the abdominal sympathetic; and diminution in the power and tone of the muscles of the abdominal wall.

Salvarsan.—A. Evans states that as regards the primary lesions treated he has observed rapid improvement, with complete disappearance of the chancre in all cases before the fourteenth day, and in most cases earlier than this. Secondary manifestations have also disappeared very rapidly.

Salvarsan in Frambesia.—H. Alston states that Salvarsan is the best drug for use in yaws. He has no doubt that this fact has been discovered in every yaws hospital. The experiments in Trinidad have contributed to knowledge in four directions: The serum of cases recovering under salvarsan has been shown to have a curative effect; Nostril yaws tubercles are not affected by salvarsan nor by serum; the milk of a goat injected with salvarsan has a curative effect.

Berliner klinische Wochenschrift.

March 13, 1911.

Neurotrophy of Salvarsan.—Geronne and Guttmann study the possible neurotoxic action of salvarsan in a number of cases favorable for such a consequence. The cases are summed up as follows: 1. Man with healthy nervous system infected with lues April, 1910, and soon afterward received an intravenous injection of salvarsan. By June he exhibited evidences of severe irritation of the meninges of brain and cord. Wassermann reaction was positive, although there were none of the ordinary superficial relapses (skin and mucosæ). Salvarsan was again exhibited and all symptoms soon vanished, save the Wassermann reaction. 2. Woman with malignant precocious syphilis, comprising nervous manifestations (she had never exhibited any neuropathy before) was treated in vain with Hg. She then received an injection of salvarsan, and all the symptoms, including meningeal irritation, subsided. Eight weeks later headache and facial paralysis recurred, although the reaction was negative. There was a prompt recovery under salvarsan. A further relapse occurred, consisting of facial paralysis, with psychical disturbance. This time calomel inunction was required to cause disappearance of symptoms. 3. Case of basal meningitis with double facial paralysis and involvement of the auditory nerves. The man had originally been treated with salvarsan. After the meningeal symptoms developed the same remedy was used successfully. But 10 days later the clinical picture recurred and KJ and Hg caused its subsidence. Numerous other cases are detailed, but all seem to be of the type of the foregoing. Meningeal irritation appeared in the course of the disease, with incidental paresis of some one of the cranial nerves. Otitis interna, accompanied once with Menière's syndrome, predominated. There was one case of optic neuritis, evidently of meningeal origin, which yielded promptly and finally to salvarsan. There was a case in which otitis interna (double) and opticus neuritis were combined, and cases of third nerve and facial paralysis. Many difficult points offer themselves for discussion. The authors can see no neurotropic action in salvarsan. In relapsing cases, when the relapses multiply, it is prudent to use the old remedies, for a time at least.

A Predilection Site for Spontaneous Fracture of the Femur in Tuberculosis Coxitis.—Ehringhaus, the author, has already compiled all the literature of atrophy of bone in tuberculous coxitis. In Professor Joachimthal's orthopedic clinic (Berlin) he has now seen six cases in which, owing to continued trophic change in the femur as a result of tuberculous coxitis, spontaneous fracture occurred at about the same site, *i.e.* where the compact bone passes into the spongiosa of the condyles. This secondary atrophy of the femur as a result of the coxitis, and which is often in evidence to radiography, corresponds fully to atrophy of the bones of the hand after caries of the elbow or shoulder joints, and atrophy of the bones of the feet after caries of more centrally placed joints.

Healed Pyopneumothorax from Swallowing a Piece of Dental Plate.—The lesion was of the worst type, the discharge having a fetid, ichorous character. Nicol, the regiment surgeon who reports the case, emphasizes the fact that pyopneumothorax is due almost wholly, at least in the medical mind, to tuberculosis. Cases from swallowed foreign bodies are but little known. The fragment of plate lodged in the esophagus was large and could easily be grasped and held, but extracted only with difficulty. For a considerable interval the patient, a young soldier, was but little affected, either in his functions or sensations. But all at once symptoms of infection appeared, evidently a beginning pneumonia. No well-defined pathogenic germs could be found for nearly a week—nothing but bacteria of putrefaction; but later streptococci appeared. There was little sputum, but marked fetor of breath. A pneumothorax soon developed and soon a collection of pus was in evidence found on puncture to be thin, greenish-yellow, and fetid. The germs in this pus comprised streptococci and bacteria of putrefaction. The pleural cavity was incised, a piece of rib resected, and irrigation maintained. There were morphological evidences of gangrene of the lung, and later a sequestrum came away, this separation having been preceded by high fever and threatened sepsis. From that time on improvement was steady. The cavity closed down to a fistula, which was easily obliterated. The exact cause of the pneumonia was obscure—it might have come from esophageal perforation, or aspiration of food.

Münchener medizinische Wochenschrift

March 14, 1911.

Paratyphoid Infections.—Rolly, an authority on this subject, begins a serial study of it with the recitation of a long series of cases, giving the temperature-curves, the presumable causal nexus, the relapses, etc. A general epidemic feature does not seem to be always in evidence. In some cases a pure bacillary infection (typhoid sepsis) seems assured: while in others there were clinical evidences of acute gastroenteritis, cholera nostras, dysentery, food poisoning, etc.—which seemed to set apart such cases from a simple bacillemia. Paratyphus infection is often seen under circumstances which seem to assure a primary food poisoning, *i.e.* after ingestion of delicatessen meats and fish and bakers' wares of all kinds, as well as sugar preserves and the like. To exemplify, the author cites a local epidemic (1906) in which the illness of 250 persons could be ascribed to the ingestion of legumes. The illness lasted from two to four days and was of the type of gastroenteritis. Apparently the cooking of the legumes was sufficent to set free the toxins of the bacilli. The author has found coctostabile poisons in such vegetables, which could explain an affection like the preceding. The presence of a gastritis or gastroenteritis is more frequent in proportion than a typhoid syndrome; so much so that many writers believe this clinical phase to be a sufficient differentiation of paratyphus from typhus proper. Distinction can, in fact, be established only by bacteriology; for typical typhoid may be set up by *B. paratyphus*. Of numerous cases given in detail it is easy to see that clinically they could pass for ordinary typhoid. All the more characteristic clinical phenomena were in evidence. The most marked differences appeared in the etiology, for in each paratyphus case there was a suspicion of food poisoning of some kind, with occasional propagation by kitchen ware. The true differentiation was, of course, bacteriological. Rolly's study is here interrupted. Dr. Schmidt continues its first installment with a study of the ubiquity of the *B. paraty-*

phus, which enables it to figure in the causation of so many opposed conditions. This germ is not ubiquitous in the sense that dust germs of various kinds are always in evidence. It resembles rather the *B. coli,* in that it is found in the intestinal discharges of various animals in health or sickness. The *B. paratyphus* is very commonly present in the intestinal discharges of healthy pigs. The resemblance of this germ to the corresponding one found in diseased man is clear and striking. This evident presence of *B. paratyphus* in healthy animals had led clinicians to exclude chopped meat, etc., from all sick dietaries. The danger to the healthy from sausage meat, meat puddings, etc., is evidently great, especially as sausage skins are so freely employed in this capacity. While not much in the articles of Rolly and Schmidt is strictly new, these authors are furnishing special data concerning the existence of true autumnal typhoid, and many like affections of enteric origin. As years were required to separate typhoid from exanthematic typhus so the process of differentiation goes on.

Röntgen Diagnosis of Early Pregnancy.—Edling refers to early attempts in this direction, which were successful only in the last two months or so of gravidity. Nothing of value earlier than the fifth month is to be found. The author has examined gravida for a year or more in the earlier months, and has succeeded in obtaining *x*-ray photos as early as the third month. At this early stage of pregnancy, at least up to four and a half months, a twin gestation can be made out. Abnormal seat, malformations, etc., are also recognizable. Extrauterine pregnancy may also be recognized. While the author attempts a digest of his method in a few lines, he plainly refers the reader to a subsequent article of much more ample compass, which will come out soon.

Icterus after Salvarsan.—Icterus in initial syphilis is by no means a rare coincidence. It should, therefore, not surprise the reader to find jaundice in the course of a salvarsan treatment. The only wonder would seem to be that it does not oftener occur; for the course of a salvarsan treatment might be expected to increase the percentage, on physiological grounds. It is known that salvarsan seems to set up a late icterus—in fact, the whole phenomenon is a rapid one. Now an early syphilitic untreated can set up the same syndrome; so that we are anxious to learn the part played by salvarsan injections. This would seem to be involved in the more recent articles on salvarsan as a protective and curative factor in lues.

Deutsche medizinische Wochenschrift.

March 16, 1911.

Total Congenital Absence of Teeth.—The boy who furnished the case was 12 years old when first seen. Wieting of Constantinople, who reports the case, notes particularly the absence of other congenital defects and especially those that often accompany defects of dentition, to wit, anomalies of hair and nail growth. A sort of compensatory hypertrophy of the lips was present, and these, with the buccal muscles and tongue, were all the structures which could be utilized in masticating food; for alveolar processes or gums were as good as wanting. The literature of the subject is very scanty and defective. The boy was evidently well nourished—at least nothing is said to the contrary. Congenital diseases such as might affect the bones were notably absent (rickets, lues, cretinism).

Transitory Traumatic Glycosuria of the Newly Born.—For many years it has been known that children subjected to operative measures for delivery have shown sugar in the urine—both in the living and dead. This phenomenon has not been discussed or noted in recent years. Hoeniger has taken up this matter, perhaps for an inaugural dissertation, as he has not yet taken his degree. He evidently intends to add the term traumatic, as well as transitory, to characterize the glycosuria. Four cases are cited, all of severe labor requiring operation. The glycosuria tends to appear suddenly after the mechanical compression of the fetus. Doubtless if all the instrumental deliveries in a large clinic were tested from this point of view, the condition would be found to be almost physiological. Until this is done speculation seems worthless.

Agioma of the Parotid Gland.—According to Harras and Suchier not over a dozen cases of this affection have ever been placed on record. Others are upon record that cannot be accepted as authentic, for one reason or another, as shown by an analysis of all accessible cases, real or imputed. The observation of the authors is evidently intended to standardize the subject matter for the benefit of future observers. Thus their own case is congenital, hypertrophic, and represents a simple hypertrophy of the vessels. From this standpoint a dozen or so of recorded cases may pass muster. Other cases reported as angioma, with cell changes, do not come under this head. The question of treatment must be considered, for a simple hypertrophic angioma occurring within the first year of life should be extirpated at once; the dangers from hemorrhage increasing with age.

Protective Vaccination.—Levy, while dealing primarily with the old cowpox vaccination, mentions conditions which apply to all attempts to secure immunity from infectious diseases. The more that variola is stamped out by vaccination and revaccination with cowpox the greater becomes the sceptical attitude toward the preventive power of this vaccination. The belief has grown up that the disease has died a natural death, so why should an individual submit himself to the questionable results of inoculation with an animal poison? Lord Lister has called this *laisser aller* attitude a "most tremendous experiment." In Germany, where domestic vaccination has become to some extent a necessary preventive law, with seemingly resulting immunity of all home dwellers to smallpox, there occurs from time to time a smuggling introduction of the disease from adjoining countries. All legislation in respect to introduction of the disease leaves many loopholes which render dissemination possible. In addition the subject of anaphylaxis enters here. Granted that vaccinia as an equivalent of variola be transmitted at the wrong moment for neutralizing the latter, may not vaccination develop an anaphylaxis to variola? The problems opened up by this suggestion are numerous. In the meantime the author does not appear to believe much in the five year limit between primary and secondary vaccination. This interval, after exposure in a given case, should not be held to prohibit the incarceration of an exposed person, provided the latter has not been duly revaccinated.

The Meiostagmine Reaction in Infantile Tuberculosis.—L. Concetti describes the meiostagmine reaction as produced by specific substances found in the blood of patients, which appear with variable superficial lesions when these sera are added to specific antigens diluted with an 85 per cent. solution of sodium chloride. The author tested the reaction in babies, in whom it is known that the cutireaction often fails in miliary tuberculosis and meningitis, and in whom the examination of the sputum is impossible. The materials for the reaction are a dilution of 1-20 with sodium chloride solution of the serum of the patient and a dilution of specific antigens 1-50. In thirty-six cases tested by the author the reaction was positive in all. These cases were also positive when the cutireaction failed. In twenty control cases of children sick with other diseases the reaction was absent in all.—*Il Policlinico.*

Book Reviews.

Die Bestätigung der künstlichen züchtung des Krebserregers, sowie weitere geschwulststatistische Mitteilungen über Familien-, Ehegatten-, und endemischen Krebs. Von Robert Behla, Regierungs- und Geheimer Medizinalrat. Berlin: Verlagsbuchhandlung von Richard Schoetz, 1910.

This pamphlet is chiefly a polemic against those who do not believe in the parasitic theory of cancer, and a defense of Behla's own published statements that cancerous tumors are due to the stimulus of a parasite belonging to the group of Myxomycetes, and that this parasite can be cultivated. Behla acknowledges that the inoculation of cancer from person to person is rare, perhaps, according to his ideas, not over 1 per cent., and that therefore there is no cause for alarm over the dangers of infection, but he is firmly convinced that cancer is increasing greatly in frequency, and that it occurs much more often in certain districts than in others. He also believes in "cancer houses." The value of his opinion may be judged from the following case, cited as an evidence of the existence of a "cancer house." A man died after a long illness from cancer of the stomach. His widow sold the house to another man who was in good health. This man lived in the same room and had his bed in the same place as his predecessor. About a year later the second man began to suffer from cancer of the stomach. Such logic has long been the bane of medicine.

The Diseases of Infants and Children. By Edmund Cautley, M.D., (Cantab.), F.R.C.P. (Lond.), Senior Physician to the Belgrave Hospital for Children, Physician to the Metropolitan Hospital, formerly Casualty Physician and Assistant Demonstrator of Physiology at St. Bartholomew's Hospital. $7.00. New York: Paul B. Hoeber, 1910.

It would be extremely difficult to name a work on pediatrics which within the limits of one volume covers the ground so completely as does this treatise on diseases of children. Written for the practitioner rather than for the student, it aims to present this subject with such fullness as to render reference to other works unnecessary. A careful examination of the book will reveal that hardly anything of importance in the modern developments of pediatrics has escaped the vigilance of the author. Thus, hypertrophic stenosis of the pylorus, acidosis, delayed anesthetic poisoning, and cleidocranial dysostosis are presented in ample detail. The Mendelian law of heredity is elaborately described in its applications to childhood. The chapters on the disorders of metabolism and growth are masterly. In fact, with the exception of the chapter on infant feeding there is little to criticise on the ground of incompleteness or inaccuracy. It is unfortunate that the author has not appreciated the importance of the modern percentage methods of infant feeding to a greater extent than is indicated by his rather brief presentation of this subject, which, however, is striking for its simplicity, and is at any rate valuable as a reflection of the English viewpoint in comparison to that of America and Germany. A liberal amount of space is devoted to surgical affections, diseases of the eye, ear, and skin, unlike the average general textbook on pediatrics. The subjects of adenoids and hypertrophied tonsils are discussed with due regard to both surgical and conservative methods of treatment. As examples of the author's ripe experience and extensive knowledge of the literature, the following conditions are fully described: suprarenal apoplexy, ateleiosis, precocity, hemihypertrophy, carbohydrate fever, congenital laryngeal a complete treatise on diseases of children, particularly suitable for the practitioner who is already familiar with the subject and who desires to supplement his own experience and knowledge with the latest advances in this stridor, Sprengel's deformity, pulmonary osteoarthropathy, etc. This book may be recommended without reserve as growing specialty.

The Hygiene of Infancy and Childhood and the Underlying Factors of Disease. By A. Dingwall Fordyce, M.D., F.R.C.P. (Edin.), Extra Physician Royal Hospital for Sick Children, Edinburgh; Author of "Diet in Infancy." New York: William Wood & Company, 1910.

Unlike the many popular books dealing with the subject of the care of young infants and children, this book is a scientific presentation of the facts of modern medicine in correlation with the subject of pediatrics. It is therefore not intended for the "zealous mother whose drawing-room table is littered with books on infant feeding, infant hygiene, child nurture, and so forth," but is offered to busy practitioners as a means of being placed *au courant* with various aspects of pediatric medicine which would otherwise necessitate wide reading, and to young physicians it is offered as the modern basis of clinical pediatrics. This book is unique in its field, and supplies a distinct want in medical literature. The seasoned practical experience of the author, coupled with the results of extensive reading, has enabled him to present a work that may be regarded as authoritative. The systematic grasp of the subject-matter is revealed in the classification, in which the chapters are grouped under the following headings: the food factor, the factor of heredity, the factor of environment, the bacterial factor, and the factor of age period. The first of these includes chapters on food and metabolism, the outlines of diet for healthy children, and digestive and metabolic disorders. The problem of heredity and its clinical aspects are exhaustively treated, while to environment is accorded its full measure of importance. There are chapters on bacterial infection and its peculiarities in childhood, and on particular bacterial infections as they occur at this period. The factor of age period is dealt with in respect to the first nine months of life, to the periods from the ninth month to the close of the third year, and from the third to the twelfth year. Puberty and adolescence and the subject of the child as a social unit are the concluding chapters. This survey of the scope of the book indicates the breadth of its subject-matter, which reflects the accepted views of scientific authorities and clinicians. There are copious quotations from other writers, and the text is clad in a style of striking precision and elegance. The book may be recommended for the use of the physician who would realize his responsibility as referee in problems relating to child life.

Das Trachom in Ostpreussen. Kurzgefasste Darstellung seiner Pathologie und Therapie. Von Dr. Kusel, Stabsarzt, Gumbinnen. Halle a. S.: Carl Marhold, 1910.

Dr. Kusel covers the subject of trachoma very fully in his monograph of eighty pages. The paper is very carefully prepared, and is well worthy of perusal by all who are interested in the study of this form of eye disease.

Treatise on Diseases of the Skin. For the Use of Advanced Students and Practitioners. By Henry W. Stelwagon, M.D., Ph.D., Professor of Dermathology in the Jefferson Medical College, Philadelphia; Dermatologist to the Howard and Philadelphia Hospitals; Consulting Dermatologist to the Pennsylvania Institution for the Deaf and Dumb, to the Pennsylvania Institution for Feeble-Minded Children, and to the Widener Memorial Training School for Crippled Children; Member of the American Dermatological Association; Honorary Member of the Society of Dermatology and Syphilography of Italy; Associate Member of the Society of Dermatology and Syphilography of France, of the Vienna Dermatological Society, and of the Berlin Dermatological Society. Sixth Edition, thoroughly revised. With 289 illustrations in the text and 34 full-page colored and half-tone plates. $6.00. Philadelphia and London: W. B. Saunders Company, 1910.

The sixth edition of this well-known work not only maintains the high standard which has characterized former editions, but also includes many new features which bring it strictly up to date. These additions include an article on pellagra that has been rewritten in the light of recent American experience, and articles on sporotrichosis, grain-mite dermatitis, dermatitis due to the brown-tail moth, gangosa, tropical ulcers, ulcerating granuloma of the pudenda, granuloma annulare, and lichen nitidus. The uses of carbon-dioxide snow form a useful addition to the subject of treatment. The latter is presented with a fullness that cannot fail to satisfy the varying demands of the general practitioner. The illustrations, including many colored plates, are particularly helpful. There are copious references to the literature. As a textbook and a work of reference this book may be safely recommended for its accuracy and completeness. The typographic and artistic features are in keeping with its scientific excellence.

Care of the Patient. A Book for Nurses. By Alfred T. Hawes, A.M., M.D. With six illustrations. $1.00. Philadelphia: P. Blakiston's Son & Co., 1911.

One is surprised at the large amount of important information which the author has succeeded in presenting in this little volume of 173 pages. The essentials of medical and surgical nursing are set forth in language easily understood by persons of average education. One discerns on every page the importance accorded to technique as a prime requisite in nursing. Small details are not disregarded, and the value of method in the nurse's work is emphasized. There are chapters on medical and surgical nursing, after-care of the patient, and maternity nursing.

Practical Points in Nursing. For Nurses in Private Practice. With an Appendix containing rules for feeding the sick, recipes for invalid foods and beverages, weights and measures, dose list, and a full glossary of medical terms and nursing treatment. By Emily A. M. Stoney, Graduate of the Training School for Nurses, Lawrence, Mass.; late Superintendent of Training School for Nurses, Carney Hospital, South Boston, Mass. Fourth Edition, thoroughly revised. Containing ninety-seven text illustrations and eight colored and half-tone plates. $1.75. Philadelphia and London: W. B. Saunders Company, 1910.

Perusal of the title page of this book indicates its purpose and scope. The fact that it has already passed through four editions indicates the favor with which it has been received. In this, as in previous editions, the author has attempted to explain, in popular language, the entire range of private nursing as distinguished from hospital nursing. A large amount of new matter has been added, including the latest nursing technique and the newest procedures. The chapters on the nurse, the sick-room, the patient, accidents and emergencies, nursing in special medical cases, nursing of sick children, physiology and descriptive anatomy, and the appendix, which contains valuable tables and recipes, all serve to make this book a reliable and complete textbook that can be safely recommended.

Practical Physiological Chemistry. A book designed for use in courses in practical physiological chemistry in schools of medicine and of science. By Philip B. Hawk, M.S., Ph.D., Professor of Physiological Chemistry in the University of Illinois. Third edition, revised and enlarged. With two full-page plates of absorption spectra in colors, four additional full-page color plates and 127 figures, of which 12 are in colors. Philadelphia: P. Blakiston's Son & Co., 1910.

This new edition differs but little from the previous revision. A few additions and corrections are noticeable, and a few new tests and methods have been included. As a work on physiological chemistry, the present volume has much to commend it; it is thorough, there is sufficient detail, the tests are ample and well selected, the type and press work make it pleasant to read, and the book will lie open at any given place—a great comfort, if not an absolute necessity, especially for laboratory work. The only criticism we have to make is that there is too much repetition. Several tests are repeated in practically the same words. For example, the tests on pages 23 to 30 will be found again on pages 300 to 307; and a great deal of pages 310 to 333 has already been given in the earlier part of the book.

Progressive Medicine. A quarterly digest of advances, discoveries, and improvements in the medical and surgical sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia; assisted by Leighton F. Appleman, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. December 1, 1910. Philadelphia and New York: Lea and Febiger.

The present issue of Progressive Medicine runs on the same lines as heretofore. There is one new contributor, Dr. Lavenson, who supplies the article on Diseases of the Digestive Tract and Allied Organs, the Liver, Pancreas, and Peritoneum. The other articles are by Dr. Bradford, on Diseases of the Kidneys; Dr. Bloodgood, on Surgery of the Extremities, Shock, Anesthesia, Infections, Fractures, Dislocations, and Tumors; Dr. Belfield, on Genito-Urinary Diseases; and Dr. Landis, on Therapeutics. One of the features of this publication is the length of time its contributors remain with it; some of them have been with it almost from the start, and their length of service gives to their contributions a continuity which is of distinct value.

Hereditary Characters and Their Modes of Transmission. By Charles Edward Walker, M.Sc., M.R.C.S., L.R.C.P., Director of Research in the Glasgow Cancer Hospital; formerly Assistant Director of Cancer Research in the University of Liverpool; sometime Demonstrator in Zoology, Royal College of Science, London; Author of "Essentials of Cytology," etc. New York: Longmans, Green & Co.; London: Edward Arnold, 1910.

The object of the author has been to apply recent discoveries, as well as experimental work upon cells, to some problems in heredity. He has attempted to harmonize the results of Mendelian experiments with the observations of the Biometricians, by showing that some parts of the cells involved in fertilization are distributed in an alternative manner, while other parts simply divide in bulk. The author also puts forward for the first time a complete theory, dividing characters into individual and racial, and attributing to each a different mode of transmission. He suggests a fresh hypothesis regarding the problem of sex. This book requires careful and slow reading, for it probes into the most involved problems of biology; nevertheless with the aid of the introductory chapters on cell life, the cultured reader is enabled to understand these abstruse problems. Among the subjects discussed are the various theories of heredity as proposed by Lamarck, Darwin and Wallace, Weismann, Oscar Hertwig, and by De Vries; immunity, adaptation, the effects of environment, and the determination of sex.

Die Mikroskopischen Unterschungsmethoden des Auges von Dr. S. Seligmann, Augzenart in Hamburg. Zweite, gänzlich umgearbeitete und erweiterte Auflage. Berlin: Verlag von S. Karger, 1911.

This volume, which is one of 324 pages, is intended to give the modern technique of the microscopal study of the tissues of the eye, and of the microorganisms and fungi, pathological and pyogenic, which affect the eye and its adnexa. The technique of examinations in the fresh and in the hardened state of the tissues is given, also the various methods of staining best adapted for the different tissues and the various microorganisms. The work is one that should be at the command of every worker in this field. The fact that the work now appears in its second edition is sufficient evidence of its excellence.

Theorie und Praxis der Inneren Medizin. Ein Lehrbuch für Studierende und Ärzte. Von Dr. Erich Kindborg in Bonn. Erster Band. Die Krankheiten der Zirkulations und Respirationsorgane. Mit 47 abbildungen. Berlin: Verlag von S. Karger, 1911.

In presenting a new book on the practice of medicine, the purpose of the author has been to incorporate in the text sufficient anatomy, physiology, physics, chemistry, pharmacology, bacteriology, etc., as will enable the student to fully grasp the subject without further reference to works on these fundamental studies. His object has been not to discourage the preliminary mastering of these studies in the medical curriculum, but rather to facilitate a rapid and simple coordination of subjects that may at the moment be remote in the memory of the student. Another object of the author has been to allot a larger amount of space than is usual in works of this kind to therapeutics. The plan of the book is an admirable one and if the forthcoming volumes maintain the standard set in the first volume, one can predict a wide popularity for this work, at any rate among German readers. The present volume deals with the diseases of the circulatory and respiratory organs. These are described with an unusual degree of thoroughness and of regard for the practical needs of the physician. The subject of treatment is given in considerable detail, with the introduction of prescriptions that will be found of most frequent service. The size of the volume is convenient for facile reference, and the paper, typography, and illustrations leave nothing to be desired.

A Manual of Pharmacy for Physicians. By M. F. D. Lorme, M.D., Ph.G., Lecturer on Pharmacy and Pharmacology, Long Island College Hospital, New York. Second Edition, with 19 illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

From the preface of this work we learn that "the section considering prescription Latin has engaged the special attention of the author"; also that "some original ideas have been introduced which it is thought will facilitate teaching the student to employ *correct* Latin when writing prescriptions"; and further, that "the methods heretofore employed have signally failed, as 95 per cent. of the prescriptions presented at the pharmacists' of to-day will show." The book certainly abounds with "original ideas" on the subject of Latin, as witness the following: Emplastri adhæsivum, Cerati resinæ compositum, Tablettis orales, Tablettis compresa, Pilulas laxativa compositæ, Pilulas rhei compositæ, Pilulas antidyspeptica, Pilulas cathartica compositæ, Pulveris potassii bromidi effervescens cum caffeinæ, Olei sinapis volatile, Liquoris phosphatum acidus, Aquæ aurantii flores, Aquæ amygdalæ amari, Divide in chartulæ, Divide in pilulæ, Aquæ destillati, Cretæ camphorati, Carbo (as a genitive); and there are many others. We are of the opinion that the use of this book will certainly ensure the prompt disappearance of the 5 per cent. correctly written prescriptions. But if teachers cannot write Latin, it is small wonder that their pupils cannot. It is to be hoped that the author's lectures on pharmacy and pharmacology are not on the same plane as his efforts in teaching Latin.

Society Reports.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held February 20, 1911.

THE PRESIDENT, DR. REYNOLD WEBB WILCOX, IN THE CHAIR.

Acute Dilatation of the Stomach Following Surgical Operations.—Dr. EDWARD WALLACE LEE, in this paper, said that this is among the least frequent but most serious complications which may follow any operation, but especially those in the abdominal and pelvic cavities. As, after an operation, the surgeon frequently left his patient under the care of the family physician, it was appropriate that this subject should be presented for discussion before a general medical society like this. The condition usually came on within twelve or fourteen hours after the operation, and in one case he had observed it within one hour after the patient had been put to bed. The earlier symptoms were apparently those of shock, that extreme kind of shock accompanied with intolerable vomiting—first of the contents of the stomach, then of glairy mucus, and, if continued, of mucus streaked with blood. Internal hemorrhage could be excluded by taking into consideration all the details of the operation. As to the etiology, his experience had not been such as to enable him to determine upon any one definite cause. Various theories had been suggested, but experience so far had shown that this sequela may follow different surgical procedures, regardless of the anesthetic or of the location, extent or character of the operation. Many mechanical causes had been mentioned, such as spasm of the pylorus, volvulus of the stomach, kink of the duodenum, and pressure on the mesenteric vessels, but it was not to this class that he especially referred, as such causes, if present, were self-evident. The question had been raised whether the condition is due to a neurosis, producing paralysis, and thus permitting the enormous formation of gases, or to an irritation producing continued gastric oversecretion. From his own observation he was inclined to look upon it as due to a neurosis, some serious vasomotor nerve disturbance, rather than to any direct irritation of the stomach itself. The general condition of the patient was recognized as serious from the first. He was restless and the respirations were frequent and shallow, the pulse rapid and thready. His aspect indicated that his tissues were deficient in water; he looked pinched and as if he had aged suddenly, and his skin was cold and clammy. Diarrhea was sometimes observed, and in nearly all cases the urine was scanty. On inspection and palpation the stomach was found to be enormously distended and bent upon itself. Generally there was a sharp kink in the lesser curvature. The distention, extending toward the left side, might even cause bulging of the ribs as the mass forced itself up under these and pressed upon the diaphragm; therefore causing mechanical interference with the heart's action. This, combined with the general systemic shock, brought about a condition which could readily be understood as likely to prove fatal. The speaker said he emphasized the distention toward the left because on the right side of the upper abdominal region there was flatness on percussion, the abdominal wall at times being retracted and allowing the liver to be easily palpated. This point, if recognized, was the means of greatly aiding in making the diagnosis of acute gastric dilatation. He had seen a number of these cases, but would report only a few. The cases were in males, with one exception, and between the ages of 43 and 70. Case 1. Aged 43; had been operated upon for appendicitis; two years later hernia developed on the same side; operated upon for the hernia; within four hours enormous dilatation of the stomach; recovery under the treatment adopted. Case 2. Aged 65; gall bladder case; removal of large single stone and the gall bladder; gastric dilatation within eight hours; death in thirty-six hours. Case 3. Aged 60; a cocaine habituée and physically in bad condition; suprapubic prostatectomy; acute dilatation of the stomach in fourteen hours; death. Case 4. Suprapubic cystotomy for chronic purulent cystitis; acute dilatation of the stomach within one hour; death forty-eight hours after operation. The last case cited was in a woman of 26. It did not, strictly speaking, belong to this category, as the dilatation followed, not an operation, but a burn. This was of the second degree, situated in the upper abdomen, and about six inches square in extent. Acute gastric dilatation developed three hours after the injury, and nine hours later the patient died. He mentioned this case, he said, as carrying out the idea that such dilatation is apparently of nervous origin, rather than due to actual mechanical irritation of the stomach itself. In the treatment, Dr. Lee said that mechanical irrigation was primarily indicated. The stomach should be relieved of its contents, and if necessary the stomach-tube should be left in until there was no further indication for its use. Even after thorough evacuation, the stomach would sometimes refill, not only with secretion, but with gas, and therefore the permanent use of the tube was often required. The drugs indicated were morphine, to relieve pain and shock; strychnine, to stimulate the heart and for its effect on the vasomotor nervous system (in the hope that it may bring about contraction of the distended stomach), and eserine, on account of its efficiency in inducing peristalsis. The last named was especially indicated if there was any evidence that the intestines were involved. He had never resorted to any of the surgical procedures which had been suggested, as any operation would necessarily increase the existing shock. Gastrostomy, however, might be performed under local anesthesia, and he believed that it had certain indications which were at least theoretically logical. The general line of treatment customary after all operations should not, of course, be neglected. The literature and general discussion of this subject, he thought, had been altogether too limited for a condition of such importance and one which so often proved fatal (in 75 per cent. of cases), and this was the principal reason why he had presented it.

Dr. ROBERT T. MORRIS said that we had to account for several features of acute gastric dilatation along some of the newer lines of knowledge. With the condition in question, increased peristalsis and antiperistalsis, and an extreme degree of morbid hypersecretion, followed upon the initial disturbance. Shock, ether, and toxins are all known to disturb secretions of the chromaffins, and if the products of deranged chromaffin secretion overstimulated the inhibitory nerves of the stomach it would result in practically the same effect as cutting the vagus, so far as the phenomenon of dilatation was concerned. If the hormones secreted in the stomach mucosa were at the same time disturbed in action, they might overstimulate secretion of the stomach glands, and that would account for the excessive quantities of fluid in the stomach in these cases. The fluids attacked by saprophytes, in the absence of normal protection, would undergo fermentative changes, and that would account for the gas which is produced in such quantity. He believed that while shock, ether, and toxins could all disturb the cerebrospinal system, with consequent suspension of action of the vagus, the cerebrospinal system, as a later development of the embryo, was probably more resistant than the primitive sympathetic system, and it was to the latter that we were to look for an explanation for the phenomena of acute gastric dilatation. Dr. Lee's case of gastric dilatation following the receipt of a small superficial burn of the abdomen was particularly significant as relating to this view. Heat transformed some of the albuminous tissues

into toxalbumin. It looked as though in this case the toxalbumin, absorbed, had overstimulated the inhibitory nerves of the stomach by way of deranged chromaffin secretions, and had secondarily induced the hormones to stimulate the secretory glands of the stomach to the point of forming great quantities of abnormal products. Practical treatment of cases of acute gastric dilatation consisted of two chief resources, and these were very effective in giving relief. If the patient was placed upon the abdomen, bearing rather more upon the right side, we had mechanical compression of the dilated stomach and unkinking of duodenal angulation. If the stomach was then washed out every hour or two with the stomach tube, decomposing stomach contents with their poisonous saprophyte products were removed. The patients then commonly went on to recovery in a few days.

Dr. Robert Coleman Kemp said he had seen six cases of postoperative acute dilatation of the stomach, of which two died and four recovered. It might have been only coincidence, but all were abdominal cases in which there had been considerable manipulation of the viscera. He thought that postnarcotic vomiting should always be regarded with suspicion. In this acute dilatation the stomach was generally not alone concerned. According to his experience, there were four types: the pure gastric, the gastroduodenal, the gastrointestinal, and that in which there is an acute dilatation engrafted on a stenosis of the pylorus with chronic dilatation. The differential diagnosis must be made by means of the stomach tube and aspirating bulb. First aspirate the contents and then wash the stomach. If, after the stomach had been completely emptied, the intestines were found to be still dilated, the case would be seen to be one of mixed type. Acute dilatation was especially liable to occur after cesarean section, probably as a result of the sudden relaxation of intra-abdominal pressure. If a case were purely gastric in character, the patient should be placed on the right side or belly, and the stomach thoroughly washed out every two hours. If it were of mixed type, resort should be made to the Fowler position. By way of medication, Dr. Kemp was accustomed to employ calomel, magnesium sulphate, strychnine and eserine, as well as large doses of belladonna. He never used morphine, and believed that it could only prove harmful in these cases. No food should be given by mouth and proctoclysis should be employed for thirst. Continuous enteroclysis with normal saline solution, for 30 to 40 minutes, with a recurrent tube, the temperature of the solution at 115°-120° F., was of great value to help start bowel action. It also relieved intestinal tympanites in the mixed cases.

Dr. A. Ernest Gallant said that the first case of this acute dilatation he had seen was in 1906, when, just before the patient's death, the whole operating room was flooded with the dark greenish contents of the stomach. The case was one of urachal abscess pointing at the umbilicus, and the anesthesia had not been of long duration. Since then he had seen a dozen cases, and the dilatation had usually come on some three days or more after the operation. In one instance it was not until the tenth day, and he had heard of cases occurring after six weeks. In his experience, the patient at first seemed to be doing well, but later there came on a sort of overflow vomiting. Sometimes a pint or a quart of fluid was spilled over, and very soon the vomitus became of a dark green color. A study of the two or three hundred cases on record seemed to show that the origin of the dilatation was chiefly mechanical, and personally he believed the cause of the trouble to be mechanical compression of the duodenum as it passes behind the mesenteric vessels, as described by Byron Robinson. After this condition is established the toxemia portrayed by Dr. Morris no doubt prevails. In the treatment he relied principally on posture and washing out of the stomach with gallons of water. He had found it much simpler to do lavage with the patient lying on the left side, but later it was well to turn him on the other side. He did not believe the intestines were involved in these cases, for if this were so we would have peritonitis, and no peritonitis had been noted.

Dr. Achilles Rose called attention to the fact that acute dilatation sometimes occurred in cases where there had been no operation. This, he said, had been noted in patients who had previously had gastric dilatation in connection with stenosis of the pylorus, and the acute trouble appeared to be due to the cutting off of the existing compensation.

Posture as an Aid in the Diagnosis and Treatment of Cardiac Affections and Dropsical Conditions of Various Origin.—Dr. Henry W. Berg read this paper (see page 609).

Dr. John Winters Brannan said he would be glad to apply the good advice which Dr. Berg had given in his highly suggestive paper. In his own observations in the various hospitals he had frequently noticed the employment of posture, but it was usually in surgical cases. He had never used the Southey tubes, but it seemed to him that Dr. Berg's adaptation of this device in conjunction with the modified Fowler position constituted a real advance of great practical importance.

Dr. Egbert Le Fevre spoke at some length of the conditions prevailing, and of the effect of posture, in different valvular diseases of the heart. In mitral disease, he said, the ventricle could not empty itself as completely with the body in the prone position as when it was upright. In aortic regurgitation we had to deal with a question of intracardiac dynamics, rather than of hydraulics. Any case which had to have the upright posture was one to be regarded as doing the best that it could under bad circumstances. When a patient was more or less confined to this he was getting a certain amount of comfort at great expense to the circulation. By keeping such a patient flat for a time, and giving him morphine, we could bring about a readjustment of the circulation which was often of great service. In these cases nature was trying to meet a deficiency, and the value of the bed-rest was that it kept the patient in a posture which enabled nature to act in as favorable conditions as were possible under the circumstances.

Posture in Surgery.—Dr. Alexander B. Johnson read this paper.

Posture in Obstetrics.—Dr. George Livingston Brodhead said that for convenience we might speak of (1) posture in pregnancy, (2) posture during labor, and (3) posture during the puerperium. During pregnancy patients were advised to rest for an hour or two each day, preferably after luncheon, with the clothing loosened and the corset removed. In the early months it was well to warn the patient to take no unusual exercise at the times when she had menstruated before the pregnancy, and if she had a miscarriage previously the recumbent posture should be enjoined for a week at such times. For retrodisplacements, in addition to the pessary, the knee-chest, or at least the lateral prone, posture, for a certain part of each day, should be insisted upon. During the first stage of labor the patient should be kept out of bed as far as possible, but if she were tired out she should lie in the lateral prone posture. In women with pendulous abdomens more progress was usually made if the patient was kept in bed with the uterus held up by a binder. The knee-chest or lateral prone position was essential when in hydramnion the membranes were artificially ruptured, to prevent prolapse of the cord, and was especially called for when such prolapse had already occurred. Considerable attention was given in the paper to the rectification by posture of faulty presentations and positions, and

King's methods by thigh pressure were described. For delivery, Dr. Brodhead said he employed the dorsal position exclusively, though he could understand the advantage of the lateral position in cases where the pains are very violent, with rapid advance of the head. On the other hand, he believed the danger of sepsis was greater with this position. The Walcher position, which increased the conjugate diameter of the pelvic brim by one-third of an inch or more, was to be used whenever there was slight disproportion between the head and the superior strait. The forceps were usually applied with the patient in the lithotomy position but when the head had begun to distend the outlet the thighs should be extended, in order to relieve the strain on the soft parts. After delivery the patient should be allowed to assume either a dorsal or lateral position. In the course of a few days, if the breasts would permit of it, she should begin to spend her time equally between the dorsal, lateral and abdominal positions. In his experience, no harm had followed the use of the upright position for the evacuation of the bladder and rectum in cases where the patient could not accomplish this while lying in bed. At the end of five to seven days, or even earlier if drainage were not free, the patient might be permitted to sit up in bed, and in ten to fourteen days, as a rule, to sit in a chair. She should not be allowed to walk until bright red lochia had ceased. In septic cases the use of the Fowler position was most valuable for drainage. At the end of the second week a vaginal examination should be made in order that retrodisplacements might be corrected by appropriate postures and other treatment. In conclusion, Dr. Brodhead said that while the fact must be recognized that in many cases position alone does not give the desired results, still, in appropriate posture we have a most valuable aid in obstetrical treatment.

Posture in Gynecology.—Dr. HENRY C. COE said that the modern medical student was thoroughly familiar with the different postures employed in gynecology, not only from the excellent illustrations in the textbooks, but from seeing them in daily use at the dispensary and in the operating room. Therefore he did not intend to inflict any elementary instruction on such an audience as this. It had seemed to him that it might be more interesting if he indulged in a few reminiscences—a weakness which might perhaps be permitted to one who had been in practice for twenty-five years. When he was an interne at the Woman's Hospital the only positions recognized were the dorsal (or "dorsal elevated"), the left lateral (Sims's), and the genu-pectoral. A gynecologist who operated on the cervix or perineum with the patient in any but Sims's position would have been regarded as a dangerous innovator. Bozeman used the genu-pectoral for his vesico-vaginal fistula operations, and Dr. Coe well recalled what a trial it was to the anesthetist, with the patient strapped to a special apparatus for one or two hours. The genu-pectoral was used for replacement of the uterus and ovaries and the tamponade more frequently then than at the present day, and he believed that we had suffered a valuable means of diagnosis and treatment to lapse into disuse. Certainly, he had urged upon his students the importance of it. He seldom saw men palpate a patient in the Sims position now, though he knew of no more useful method of detecting a prolapsed ovary or an anteflexin of the uterus or a better way of deciding whether the retroflexed organ can be replaced. He remembered that the late Dr. T. Gaillard Thomas was especially skilful in this method of diagnosis. Dr. Coe recommended it highly in the case of stout patients and in those in whom the abdominal walls are unusually rigid. The position known as Fowler's (designed to favor drainage *per vaginam*) he had seen employed many years ago. Dr. Emmet used to elevate the foot of the bed from 18 to 24 inches, not only in cases of shock and hemorrhage, but also to relieve pelvic congestion during menstruation. But of all beneficial discoveries (or rather, perhaps, adaptations), Krug's application of Trendelenburg's posture to intrapelvic surgery had marked a new era. When we contrasted the long, blind Freund's operations of twenty years ago (some of which he had known to last three or four hours), attended with a mortality of 75 or 85 per cent., with the rapid, exact work made possible by the elevated posture, he felt that he owed to the pioneer in that line a debt which we never could sufficiently repay. It was, indeed, difficult to make the present medical student, observing the results of modern technique, realize what our best and most successful operators once regarded as the only proper method of procedure.

But enough of reminiscences, Dr. Coe went on to say. His own present practice was to examine a patient first in the ordinary dorsal posture, employing the lithotomy position (dorsal elevated) position for all surgical work on the vagina. The Sims position he had entirely abandoned. In order to confirm a diagnosis of prolapsed ovary or adherent uterus the patient was placed in the genu-pectoral, which was almost his favorite position also for replacing a movable uterus and introducing a pessary. In the case of virgins, in every instance of malignant disease of the uterus, a careful rectoabdominal examination was made with the patient on her back. For palpating a movable kidney the patient was sometimes requested to sit, or stand erect, but the recommendation made in the books to examine women in the erect posture, in order to note the varying degrees of prolapse of the uterus, was seldom carried out in private practice. Herniæ, of course, were often examined with the patient in this position. Of Trendelenburg's posture it was unnecessary to speak, as everyone was familiar with it and every surgeon was provided with a table which enabled him to elevate his patient readily. It should be noted that the extreme degree of elevation originally advocated by Trendelenburg was not favored by modern operators, who were usually able to work at an angle of from 45° to 60°. Dr. Coe had found Fowler's position (elevation of the head and trunk) useful in bad pus cases, with vaginal drainage. Much might be said in regard to the patient in bed after operations. It was sufficient to state that great latitude was now allowed as to turning on the side, sitting up in bed, etc., after abdominal section. In a word, simplicity was the rule in gynecological practice, and nature was imitated, rather than forced into rigid theoretical lines.

Dr. FRANZ TOREK said that the Fowler position had now been before the profession for quite a number of years, and it was still regarded by many as the best possible in operated cases of diffuse peritonitis. He believed, however, that it was a delusion, and it was fully six years ago that he had first publicly expressed his conviction of this. In these cases the condition could not at all be compared to that where there was ascitic fluid, as had been done. In many instances the pus did not run down. If after one had got rid of all the pus possible some still remained, this was because the remaining pus was held back by adhesions, and no amount of posture would bring it down. The use of the Fowler position here, therefore, was clearly illogical.

In reply to a question Dr. JOHNSON said that in cases of purulent peritonitis, after the abdomen had been opened the nozzle of the aspirating apparatus was first put into the evident loculi of pus and then into other places where we might expect to find pus. It was very rare that the apparatus had to be resorted to after the operation, and when this was the case the very powerful suction was not employed, but a feeble suction. After suprapubic cystotomy and in some other special conditions mild aspiration was sometimes kept up for a week at a time.

Dr. Berg in closing said he had been much impressed by Dr. Johnson's description of the postoperative treatment of diffuse peritonitis at the New York Hospital, and considered this application of the vacuum principle a brilliant achievement. As to the Southey tubes, he never employed them unless he could feel edema of the patient's legs (edema of the waxy kind). It was essential that the little trocar should be inserted completely under the skin, and two tubes were generally used for each leg. By means of these tubes it was possible to drain out not only the fluid in the subcutaneous tissues, but also that which was in the pleuræ or abdomen.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held February 27, 1911.

The President, Dr. James F. McKernon, in the Chair.

People vs. Willis Vernon Cole.—Almuth C. Vandiver, Esq., Counsel for the Society, reported that recently the Police Department caused the arrest of one Willis Vernon Cole on the charge of practicing medicine without a license. The evidence was obtained by Mrs. Isabella Goodwin, a police matron, and was not submitted to the counsel before the defendant was arrested. Having been notified by Inspector John Henry Russell, in charge of the Detective Bureau, of the arrest and asked to appear in the case, Mr. Vandiver had done so. It developed that the original complaint upon which the warrant had been issued had not been signed by Mrs. Goodwin. Thereupon, upon motion of William Travers Jerome, Esq., the counsel for the defendant, the latter was discharged. Mr. Vandiver then conferred with Dr. John E. Weeks, chairman of the Board of Censors, in regard to the application to Magistrate Freschi to conduct an investigation into the defendant's practices, in order that it might be definitely determined whether or not he was violating the Medical Statute. Dr. Weeks instructed him to proceed and evidence was secured by the female investigator. This evidence was laid before Magistrate Freschi, who issued a summons, requiring the attendance of Cole. An examination was held and the police matron and the investigator of the society testified. The defendant testified that he was practicing the religious tenets of his church, and called in his behalf Virgil O. Strickler, first reader of the Church of Christ, Scientist, and Mr. Cox, of the Publication Committee of this church. The magistrate reserved decision, and the Counsel for the society filed a lengthy brief in which it was contended that the clause of the medical statute relied upon by the defendant, to the effect that nothing in the medical practice act shall be construed to affect the practice of the religious tenets of any church, applied in no respect—the provision of the State Constitution guaranteeing absolute freedom in religious belief and worship. This view was accepted by the magistrate, who decided to issue a warrant for the arrest of Cole. This he did and the defendant was held for trial in the Court of Special Sessions. Mr. Jerome stated to the Police Court that Mr. Cole and his co-religionists were desirous of having a test case prepared in order that it might be definitely determined whether Christian Scientist practitioners were within the protection of the statute. Apparently, however, Mr. Jerome withdrew from this position, as he made and argued, on Friday, February 17th, a motion before Judge Warren W. Foster, in the Court of General Sessions, to remove the case from the three judges at Special Sessions to trial in the Court of General Sessions before a jury. This motion was opposed by the District Attorney's representative and by the counsel for the Medical Society and was at present under advisement.

Bills Relating to Vivisection.—Dr. James Pedersen, chairman of the Subcommittee on the Anti-vivisection Bills, stated that the Committee on Legislation desired to report adversely on all four bills relating to vivisection or to the so-called control of vivisection now before the Legislature.

Senate Bill (Int. 397), introduced by Mr. Pollock, and Assembly Bill (Int. 532), introduced by Mr. Parker, both entitled "An Act to amend the education law, in relation to preventing cruelty by conferring upon the board of regents of the University of the State of New York the power of supervision of experiments on living animals," should be opposed on the ground that should they become laws the supervision of vivisection would be in the hands of a distinctly biased committee, whose authority would seem to be final in the matter, to the great detriment of the progressive research work now being carried on.

Senate Bill (Int. 310), introduced by Mr. Bayne, entitled "An Act to create a commission to inquire into the extent and nature of the practice of experimentation on living animals, and the condition of the laws of the State relative to the proper protection of scientific experimentation without danger of unnecessary cruelty," and Assembly Bill (Int. 286), introduced by Mr. Hoey, entitled "An Act to establish a commission to inquire into the extent and nature of the practice in this State of experimentation on living animals, together with the condition of the laws of the State relative to the proper protection of scientific experiments without danger of unnecessary cruelty," should be opposed on the ground that such a commission, if appointed as suggested, would open the way to a minority report against vivisection, on which minority report the Legislature could take further adverse action.

In view of these facts, the Committee on Legislation moved a resolution to the effect that the Medical Society of the County of New York protest against the passage of any of the bills on vivisection, or relating thereto, now pending before the Legislature.

Optometry at Columbia University.—A minority of the committee to which was referred the matter of preparing the resolutions concerning the establishment of the course in "Optometry" by Columbia University, submitted the following resolutions, the adoption of which was moved, seconded, and unanimously carried:

Whereas, Columbia University, an institution to which we have been in the habit of looking for the advancement of the standards of education, has established a course in "Optometry," to which "the attention of young men and women, particularly graduates of high schools, is called to the opportunities offered by the new profession which will be established by these two years' study of optometry," quoting from the Columbia Catalogue, and to the entrance of which "there is no limit as to age, and we do not require any examinations for admission," as stated in answer to a letter of inquiry; and

Whereas, The two years referred to include only the study of plane trigonometry, physics, theoretical optometry, theoretical optics, physiological optics, and anatomy and physiology of the eye only, but none of the rest of the body and nothing at all of pathology; and

Whereas, Many eye diseases and disturbances of vision which lead persons to seek relief by the use of glasses are but the symptom or outward expression of general pathological conditions or of the eye itself; as in diseases of the general and arterial system, such as diabetes, nephritis, arteriosclerosis, cerebral hemorrhage, etc.; of diseases of the general nervous system, as brain tumors, tabes dorsalis, etc.; of functional nervous disorders, as hysterical amblyopia; toxic amblyopias due to alcohol, arsenic, lead, tobacco, etc.; or due to diseases of the eye itself, as retinitis, neuroretinitis, retinal hemorrhage, optic nerve atrophy, glaucoma, cataract, etc.; and

Whereas, In order to determine these conditions, it is

imperatively necessary that the examiner should have a good general medical education and a long clinical experience, especially with the ophthalmoscope, and be able to appreciate and use a mydriatic; and

Whereas, It is utterly impossible for one so immature, and with such a limited education as can be obtained from the course of study only, to examine the eyes thoroughly and to determine when these conditions exist; and

Whereas, The false sense of security given to the public by the certificate of Columbia University that these immature and imperfectly qualified persons are capable of properly examining the eyes will constitute a serious menace and a great danger to the community; and

Whereas, The examination of the human eye and the correction of refractive errors is a part of the practice of medicine, and the instigation of such a class of individuals to practise optometry tends to lower the requirements now necessary for medical practice; therefore be it

Resolved, That the Medical Society of the County of New York sincerely deplores and condemns the action of Columbia University in establishing this course in optometry and turning loose such dangerous inefficients upon the public, especially as it has a medical department in connection with which it can thoroughly educate them to treat the eyes and correct their refractive errors; and be it further

Resolved, That a copy of these resolutions be sent to the President of Columbia University and to the Dean of its Medical Department.

The Chemotherapy of Ehrlich with Special Reference to the Trypanosome Infection.—Dr. B. T. Terry read this paper (see page 614).

Dr. C. N. B. Camac in discussing Dr. Terry's paper referred to a case of trypanosomiasis which had been under his care for over three years. This case had contracted the disease in South Africa, where the diagnosis had been made. He had been under observation in the Liverpool and London Schools of Tropical Medicine, in the latter of which Sir Patrick Manson had had him under observation. The patient had come to New York a few months after having contracted the disease. Dr. Camac showed photographs of the trypanosomes as seen in the patient's blood shortly after his arrival here. Dr. Camac called attention to the fact that it was only ten years since human trypanosomiasis and sleeping sickness were recognized as the same condition at different stages and both due to the same trypanosome. Professor Novy in his Harvey Lecture in November, 1905, stated that "with the exception of one case, in a woman, reported by Dutton and Todd, the treatment of the human cases had thus far been ineffectual." Ten years is a very brief time in which to arrive at a positive conclusion with regard to so obscure and resistant a malady as trypanosomiasis. Professor Ehrlich, who represented the highest court of appeal in this as in many other questions, had, as given by Dr. Terry, offered brilliant explanations based upon experiment. Dr. Camac, however, stated that if he read the authorities of the various schools of tropical medicine and the writings of Professor Ehrlich aright the treatment of trypanosomiasis was still a problem far from a practical solution. Dr. Camac urged, therefore, that the laboratory worker and the practitioner in dealing with this difficult subject assume more the attitude of Professor Ehrlich, who even after hundreds of observations on animals and human beings counseled reserve with regard to positive conclusions. In Dr. Camac's case parafuchsin, atoxyl, arsacetin and antimony—the latter in metallic form and as lithium and sodium salts—had been employed. The channels were the mouth, skin, muscles, and veins. Arsenophenylglycin had been considered and the drug procured, but after consulting with Professor Ehrlich it was thought inadvisable to give the drug to this patient as he was at the time under the full influence of arsenic, which offered a contraindication. Dr. Terry had referred to the tendency of the parasite to lose its sensibility to drugs. This tendency, which occurred in the human system with drugs other than those employed to fight trypanosomiasis, presented one of the greatest obstacles in the treatment of this disease. It was important that parasites "proof" to drugs should not develop. The treatment advocated to avoid this was frequent change from drug to drug. When it seemed that Dr. Camac's case was becoming atoxyl-proof change was made to antimony. Dr. Camac called attention to the important point made by Dr. Terry of the dangerous nature of the drugs one must employ in combating this disease. The drugs were almost as deadly as the disease. In practice it was difficult to know when one was reaching the 9/10 danger line: The drug that was apparently at the 1/3 or 1/2 risk to life might without symptoms go rapidly past this point, the first intimation of such being the sudden development of serious toxic symptoms. The risk to life and of serious damage to the system in the use of these drugs was such that Dr. Camac procured them from those who had tested them out. From Sir Patrick Manson he got the antimony preparations as tested in the Lister Institute by Dr. Plimmer. For intramuscular injections antimony in Lambkin's oily medium was employed, and this particular preparation had been tested out and proven to be non-toxic, in the treatment of syphilis, in one of the British military hospitals. Even with these precautions toxic symptoms had occurred four times with Dr. Camac's patient, the last being of a severe degree and developing suddenly without increase of dose. Since the last of these attacks the patient had been entirely free from fever and able to return to business. Mercury in this respect acted much like antimony. One might administer the same dose for weeks without toxic symptoms, when suddenly salivation would develop. Like syphilis, trypanosomiasis might improve at first and then remain latent for a long period. Like syphilis, different drugs are required at different times. Like syphilis, small, oft-repeated, long-continued doses of *different* drugs were more effectual than large single doses of one drug. Like syphilis, the general health must be maintained, for, as Sir Patrick Manson believed, a high degree of resistance in the individual was the greatest single factor in his recovery. Dr. Camac showed temperature charts of this patient, extending over a period of three years, in which twenty-eight febrile paroxysms were recorded, but in which the temperature had now been normal for one year and a half and continued so up to the present. No authoritative statement could be given as to when a case of trypanosomiasis was finally cured.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held January 17, 1911.

Dr. H. S. Patterson in the Chair.

Report of a Case of Duodenal Ulcer, with a Suggestion as to Etiology.—Dr. G. A. Friedman made this report. The patient was a man, 32 years of age, whose family history showed that his mother and one sister had died of tuberculosis. Rheumatism, cancer or nervous affections had never occurred in the family and alcohol and lues were denied. The patient had never smoked. At the age of 26 he had contracted an eruption on the face which was diagnosed as lupus by prominent dermatologists. He underwent Roentgen ray treatment in which each sitting was said to have lasted fifteen minutes. As no improvement resulted he underwent a course of treatment by CO_2 snow for three months, which, in his opin-

ion, had effected a cure. About four weeks before his admission to the hospital he first felt burning pain in the epigastrium which radiated in all directions, but especially towards the right axillary region. He also had pain in the right iliac fossa. These pains occurred on three or four different occasions and finally became insupportable; he then came to the hospital. He was badly nourished; his eyes were sunken and his facial expression was one of anxiety. Nothing abnormal could be discovered about the organs of respiration and circulation. The hepatic borders were normal; there were no tender points suggesting gastric ulcer. On the right side there was tenderness characteristic of gallstones. The abdomen was grossly distended, there was rigidity of the recti muscles and, on palpation, pain in the hepatic region. His pulse was 68, respiration 20, and temperature normal. Examination of the blood showed hemoglobin 60 per cent., red blood corpuscles 3,800,000, leucocytes 15,000 and 13,000, occult blood in the stools negative. The analysis of gastric contents showed free hydrochloric acid strongly positive, total acidity 100 to 200. Stagnation of the gastric contents could not be demonstrated either macroscopically or microscopically. The urine was alkaline in reaction, had a specific gravity of 1028; sugar and albumin were negative and indican was not in excess. There was no biliary pigment, but many phosphates were present. A diagnosis of perforated duodenal ulcer was made. At laparotomy a large movable mass was found to the right of the pylorus, probably an inflammatory tumor. Fibrinous adhesions were broken up and a perforation on the posterior surface of the first section of the duodenum was found. This perforation was closed. According to the pathological picture the diagnosis of perforated ulcer was not difficult to make, although in the first days it was equally possible to think of atypical gallstone colic or chronic gangrenous appendicitis; however, the tetanic contractions and the rigidity of the recti muscles pointed the right way. The etiology was of interest in this case. Alcohol and tobacco, frequently considered a cause, were ruled out. The patient, however, still suffered from lupus which might possibly have been accompanied by the formation of a duodenal ulcer. The adhesion tumor might have given information on this point had it been possible to remove it. Duodenal ulcers had also developed after skin burns and the question arose whether the long exposure to the *x*-rays and CO_2 snow treatment might not have produced the same effect as a skin burn. It was probable that the ulcer lay dormant for a long time, as the first symptoms were observed five weeks before the operation and it could hardly be assumed that in the course of so short a time an adhesive tumor had formed. Whether the ulcer developed during the energetic lupus treatment or whether it was a mere accident in a lupus patient was an open question. The patient's occupation, that of tailor, might also be a predisposing factor.

Autoserotherapy in Chronic Pleurisy with Effusion.—Dr. J. Rudisch said that the treatment to which he was about to call attention was not new, nor could definite conclusions be drawn from the small number of cases so far treated by him. He believed, however, that the results obtained were sufficiently interesting to warrant presentation. Dr. Rudisch gave in brief the summary of three cases of pleurisy in which varying amounts of fluid withdrawn from the pleural cavity were reinoculated subcutaneously in the same patient at the site of aspiration.

Case I.—This patient was admitted to the hospital November 18 and discharged December 15, 1909. The history extended over a period of one and a half years. The symptoms during this time were cough, chills and fever, pain in the chest, night sweats, etc., and a diagnosis of pleurisy was made. When admitted to Mt. Sinai Hospital there were signs of fluid in the entire left chest. On November 20, 1,500 c.c. of fluid were withdrawn on account of the extreme dyspnea and displacement of the heart. Without any febrile reaction 30 c.c. were reinjected; this was followed by a rapid disappearance of the effusion and of the physical signs.

Case II.—This patient was admitted to the hospital October 6, 1910. For four months there had been pain in the left chest, with dyspnea, fever, loss of weight, night sweats, etc. During this time two aspirations were made, but with prompt reaccumulation of the fluid. On admission there was found fluid in the left pleural cavity. On October 11, 65 c.c. of clear fluid were withdrawn and 50 c.c. reinjected. The temperature, which had been ranging from 100° to 102° F., fell to normal October 20 and remained so until October 27, when tuberculin was injected with positive reaction. On October 29 there were signs of a thickened pleura, but not of fluid. On aspiration only 10 c.c. of fluid were obtained. On November 12 the temperature again became normal and remained so. There was no further accumulation of the fluid.

Case. III.—This patient was admitted October 19, 1909. There was a typical tuberculosis history. Signs of fluid in the right chest were elicited. Two days after admission 30 c.c. of fluid were removed, of which 15 c.c. were reinjected without any febrile reaction. Positive general and local reactions were obtained from tuberculin. On November 8 no change was found in the physical signs; 30 c.c. of fluid were withdrawn and 20 c.c. were reinjected. On November 12 only 25 c.c. of fluid were aspirated. Since the injection of the tuberculin the temperature ranged from 99° to 101° F. Since the last injection of the fluid until the time of discharge on December 13, the signs in the chest continued to improve until only slight dullness remained. On December 2 the temperature became normal. The patient gained in weight, and there had occurred no reaccumulation of fluid.

Dr. Rudisch reported another case which did not belong to this series; it was evidently one of lymphosarcoma of the mediastinum, in which the results of autoserotherapy were strikingly shown, not alone in the improvement of the general condition of the patient, but also in the marked diminution in the size of the tumor; this was shown in the *x*-ray plates presented.

The treatment of tuberculous pleurisy by autoserotherapy was first suggested by Gilbert in 1894. Small quantities of fluid were withdrawn from the pleural cavity and immediately reinjected subcutaneously. Of twenty-one cases nineteen responded with a general reaction, the temperature rising to 102° to 104° F. The two cases in which there was no reaction were uninfluenced by the treatment. In 1906 Fede, in the *Riforma Medica*, collected the cases published up to that time; he found that the consensus of opinion was favorable to the treatment in both the tuberculous and non-tuberculous cases. Good results were not, however, constant; only the tuberculous cases reacted generally. In conclusion, Dr. Rudisch said that his results, taken in conjunction with those previously published, were sufficiently encouraging to warrant more extensive use of this form of therapy, autoserotherapy.

A Case of Lymphatic Leukemia with Unusual Clinical Manifestations.—Dr. Alfred Meyer reported this case. A number of authors had recently raised their voices against the step-motherly fashion in which the clinical aspects of leukemia had been ignored, and the undue stress that had been laid upon hematological studies; this view had been taken notably by Ebstein in a monograph published in 1899. Nobody questioned the vast amount of faithful labor that had been expended upon the technique of blood examinations, and the development of tinctorial methods; but on the other hand it was not to be denied that, as a result of these studies, there had been only a slight advance in the classification of types

of this disease, and practically no advance at all in the understanding of its nature and causation, or of its rational treatment. Nor had the mystery enveloping the cause or causes of leukemia been cleared up by the large amount of experimental animal work or the intravenous injections of leukemic blood into human beings suffering from carcinoma, made by Schupfer and reported by Grawitz (*Berliner klinische Wochenschrift*, 1908). Undying fame awaited the member of their profession who finally lifted the veil from this mystery. The patient, a packer, forty-five years of age, was admitted to the hospital in November, 1910. He was married and had two healthy children. His wife had had three miscarriages. He denied both gonorrhea and syphilis. His illness began six years ago with swellings below the angle of the jaw on both sides and in the axillæ. Later his abdomen began to swell, and he suffered from dyspnea, slight loss of weight, and constipation. He claimed to have been afebrile. Dr. Meyer did not give all the details of his physical examination when he was admitted to the hospital. In most respects he presented the usual clinical picture of lymphatic leukemia. The enlargement of the peripheral glands was universal; both tonsils were enlarged and he had marked enlargement of both liver and spleen. Both of these organs were easily palpable beyond the free border of the ribs. His blood showed: red blood corpuscles, 4,600,000; white blood cells, 197,600, the proportion being one white to twenty-three red, with 98 per cent. lymphocytes. The Wassermann test proved negative. The unusual features of the case which led to his presentation before the Section were, first, the presence of a third abdominal tumor, as large as a small cocoanut, in the neighborhood of the umbilicus. This tumor was hard, somewhat irregular in contour, not tender, slightly movable with respiration, and evidently distinct from the hepatic and splenic tumors. A second unusual feature was the conversion of the right testicle into a hard mass. It appeared to him that this abdominal tumor was a large mass of more or less fused mesenteric glands, and the testicular lesion was a type of leukemia infiltration. He had never seen the latter before. It seemed to be extremely rare because in a statistical study by Ballowitz of forty-one cases of leukemia (of which thirty-two were males) there were no anomalies of the sexual organs. Another object in showing the patient was to point out a treatment that had been followed by striking improvement in a case of leukemia seventeen years ago. This was a case in which there was one leucocyte to two red blood corpuscles and there were repeated serious hemorrhages from the bowels, uterus, and nose, and painful hematomata in the skin and muscles. The treatment consisted in the main of three things: hypodermic injections of a carbolic glycerin extract of fresh sheep's thyroid (this he prepared himself, as at that time lymphatic glands were being used by mistake for thyroid), rectal injections of artificial serum, and inhalations of nascent ozone. The apparatus for the latter was imported from Belgium, the nascent ozone being obtained by silent electric discharges taking place across a series of perforations in a platinum plate coiled in a small box. There were needed besides a one-quarter-inch spark, Ruhmkorff coil, and a storage battery. In the patient whom he had shown the treatment thus far had consisted of daily injections of one ounce of a 2 per cent. solution of sodium arsenite, and although there had been a striking reduction in the size of the peripheral glands there had been no apparent influence on the abdominal lesions, and the present blood examination showed one leucocyte to fourteen erythrocytes, a relative increase of leucocytosis over the original examination.

A Case of Splenomegalic Erythremia Without Cyanosis.—Dr. N. E. Brill made this contribution. (See page 620.)

Polycythemia.—Dr. Morris Manges presented this patient, a young woman twenty-six years of age, whose symptoms began acutely three or four months ago with vomiting. Three weeks later swelling of the left side and ascites were noticed. Because of this and an increasing weakness she entered the hospital. Examination showed the spleen hard, moderately enlarged, reaching to the umbilicus, and with a number of large nodules on its surface. The liver was also enlarged and hard, with an irregular border. There were considerable ascites and slight jaundice. Cyanosis was never present. The heart showed a soft systolic murmur, heard over the precordium, with moderate enlargement of both ventricles. There was moderate conjunctival icterus. A low grade of fever was constantly present. The Wassermann test was negative. The blood showed 6,500,000-8,000,000 red blood corpuscles and 35,000 white blood corpuscles; hemoglobin 120 per cent. The clinical diagnosis favored Hanot's hypertrophic cirrhosis of the liver, but such an assumption was impossible because of the blood picture, since a more or less marked anemia was always present in this condition. The diagnosis was, therefore, an unusual form of polycythemia, of which the jaundice, the ascites, the fever, absence of cyanosis, and the unusually rapid course were the unusual features. The possible association of hepatic cirrhosis and of thrombosis of the splenic veins occurring during the course of a polycythemia was also referred to.

Pulsating Spleen.—Dr. Manges presented a young girl, sixteen years of age, who had a long-standing endocarditis (double mitral) of rheumatic origin. For a long time she had had a pulsating liver of the ventricular type and enlarged spleen. The pulsation of the spleen had been noticed only recently. A very careful series of tracings of the heart, spleen, liver, and femoral artery were taken by Dr. Alfred Cohn. These showed that the pulsation of the spleen was independent, and not transmitted from the heart, liver, or aorta. There was no fever. The Wassermann was positive. Dr. Manges referred to the extreme rarity of these cases. The seven cases previously reported were all associated with aortic regurgitation.

An Unusual Case of Arrhythmia.—Dr. Manges reported this case, which was at first one of incomplete heart block but later became complete. The most interesting feature of the case was the exceedingly rapid auricular rate (280 to the minute as demonstrated by various tracings made); the ventricular rate varied between 40 and 70. Two experiments with atropine raised the heart block, the ventricular rate rising to 120 within two hours after the administration of the atropine. The auricle could be heard beating at the lower end of the sternum; the beat was very rapid, being usually in cycles of three, the fourth beat being often merged with the ventricular systole. *X*-ray examination showed a huge heart shadow, both ventricles, especially the left, being enlarged. At the right border the pulsations of the auricle were so rapid that they could not be counted; the left ventricle pulsations were easily counted, and were only 70. No cause could be discovered for the cardiac hypertrophy; the only lesion was a double mitral murmur.

A Case of Cardiac Disease with Unusual Symptoms and Complications.—Dr. Burtill B. Crohn reported this case. The patient was a Russian woman thirty-three years old, a lace worker. The family history was negative. She denied having had rheumatism as well as other diseases known as etiological factors in the production of cardiac disease. Six years ago she was taken ill with slight cough, dyspnea, and fever, and was sick for two weeks. She stated that she was well until two years ago, when these same symptoms recurred. On this occasion she had severe pains on breathing, especially in the left lower chest. She was ill for four weeks, and was informed

by her attending physician that she had pleurisy. She had no symptoms until about nine months ago, when she presented herself at the Mt. Sinai Hospital suffering from dyspnea, cardiac palpitation, and pain in the left chest, these symptoms being of about five weeks' duration. Upon examination the patient was found to be well nourished, but markedly neurotic and hysterical. She suffered much from dyspnea. On percussion, the right border was found to be midway between the right sternal border and the right nipple line; the upper border was at the second interspace level. The left border was in its normal position. The apex beat was not palpable. A loud, rough, systolic murmur was heard, with a maximum intensity over the fifth right interspace at the sternal border. This was transmitted slightly upward and to the left. There was no thrill nor pulsations in the veins of the neck. The liver and spleen were just palpable and not pulsating. The temperature was normal. The urine gave evidences of a slight chronic nephritis. After several weeks spent in the hospital the dyspnea disappeared, the heart's action became slower, but the physical signs remained unchanged. The pulse and vein tracings taken by Dr. Alfred Cohn showed normal curves. After several months the patient returned to the hospital with a history of a recurrence of all her symptoms; her left chest had been tapped twice and much clear fluid removed. The physical condition was much the same as before, but with an increased cardiac dullness and an additional respiratory murmur along the upper left border of the breast. There were signs of fluid in the left chest to the level of the angle of the scapula. After the patient had been at rest in bed for two weeks there was a general improvement and she was discharged. One month ago she was readmitted in a serious condition. She had orthopnea, cyanosis of the lips and finger tips, rapid regular pulse of fair quality, and edema of the lower extremities. A rough to-and-fro fricture murmur of pericardial origin was audible over the upper and left cardiac borders. An examination of the chest showed signs of fluid and thickened pleura on the left side posterior to the angle of the scapula. Two days after admission the patient suddenly complained of a tingling and coldness in the right lower extremity; it was cyanotic, and felt cold from the mid-thigh to and including the toes. Pulsation in the right femoral artery was not palpable. A diagnosis of right femoral or common iliac artery embolism was made and the operation was performed by Dr. Howard Lilienthal. The incision was made over the course of the femoral vessels in Scarpa's triangle; the artery was opened but no blood appeared. A soft rubber catheter was gently passed upward into the iliac artery which encountered a soft thrombus which occluded the artery. This catheter when passed through the thrombus permitted the passage of free arterial blood from the aorta. As it was impossible to remove the thrombus without an abdominal incision, and as trauma to the aorta was feared by further manipulation, it was decided to desist for the present and observe events. On the following day there was a recurrence of the symptoms in the left lower extremity—subjective sensations of coldness, tingling, slight pain, cyanosis, and coldness in the extremity. An immediate laparotomy was performed, but on account of the distended loops of intestine it was evidently impossible to open the aorta and explore. There was some faint pulsation in the left common iliac artery; the right was felt to be well filled with a thrombus. Death occurred within twenty-four hours with general symptoms of asthenia and cardiac insufficiency. Autopsy performed two hours after death revealed the following: (1) Hypertrophy of the heart and dilatation of the right auricle and ventricle. (2) A tricuspid stenosis and insufficiency with evidences of recent vegetations on the tricuspid cusps; the opening admitted one finger. (3) There was a mitral stenosis and insufficiency with a thickening and retraction of the cusps. (4) There were thickening, sclerosis, and adhesions of the aortic cusps. (5) There was a firm fibrous band running from the left upper lobe of the lung to the anterior surface of the pericardium. There was a left hydrothorax. The lower aorta from the renal arteries down, and both common iliacs, were completely filled with a thrombus. There was also found a large, partially organized thrombus the size of a thumb firmly adherent to the wall by a broad pedicle, with the outer portion stiff and friable. The kidneys showed the presence of a chronic nephritis. The anatomical diagnosis was made of a chronic vegetative and sclerotic endocarditis (tricuspid, mitral, and aortic). There were pleuropericardial adhesions present. There was a thrombosis of the left auricle. There was possibly an embolism and thrombosis of the aorta and common iliac arteries. There was a left hydrothorax and a chronic nephritis.

A Case of Dilatation of the Aorta Due to Constriction at the Isthmus.—Dr. Albert Kohn reported this case and demonstrated the specimen. The patient was a male, fifty-six years old. With the exception of three attacks of syncope occurring years ago, and the occurrence of a cough for several years, the patient was well until one year ago, when he began to complain of cardiac palpitation. He came to the hospital because of weakness, cough, dyspnea, and edema of the legs. The examination made on March 22, 1907, showed him to be in a fair general condition, and he weighed 163 pounds. There were evidences of a marked emphysema and an area of consolidation over the right lower lobe in the axillary region. The heart was enlarged with the apex beat in the sixth interspace, 15.5 cm. from the midsternal line. The heart's action was forcible and regular. A short, rumbling, systolic murmur was heard over the apex. Both the second aortic and second pulmonic sounds were accentuated, the former ringing in character. The pulse was regular. There was a slight thickening of the vessels. The liver was enlarged, hard, smooth, and tender to touch. The spleen was enlarged, and was felt two fingers' breadth below the free border of the ribs. The hemoglobin amounted to 80 per cent.; the white cell count was 7,000. There was a small amount of albumin in the urine, together with a few hyaline and granular casts. The *x*-ray showed an enlargement of mediastinal shadow above and to the right. He developed infarcts of lungs and spleen and died April 24. The autopsy revealed a pleural effusion on the left side, with adhesions. There was also congestion and edema of the lower lobe. The right lung was adherent, emphysematous, and congested, and near the base was a wedge-shaped hemorrhagic infarct. In the pericardial sac there were about 50 c.c. of fluid. The auricles and ventricles were very much hypertrophied. The mitral opening admitted three fingers, the tricuspid five. The edges of both valves were thickened, as well as the aortic. There were lime deposits on all the valves. The cardiac muscles were pale because of parenchymatous degeneration. There was found a marked stenosis of the isthmus, with atheroma. There was a dilatation of the arch of the aorta above and below the stenosis. The foramen ovale was open. The liver was large, firm, and of the nutmeg type. The enlarged liver showed an old infarct. The kidneys were congested. This case presented none of the features characteristic of a contracted isthmus. There was no distention of the vessels of the upper extremities, nor were there distended vessels over the chest. There was no apparent difference in the vessels of the upper or lower extremities. In other words, the case presented only the features of a decompensating heart afflicted with an old endocardial lesion. Dr. Kohn presented a girl, eighteen years old, a Russian. Her general infantilism was at

once apparent. She was undersized and showed plainly a lack of development. Five weeks ago she began to complain of palpitation and precordial pain. There was no dyspnea. Her sputa were streaked with blood. The physical examination showed nothing of importance except the abnormalities in the heart and blood-vessels. The apex was in the fourth space, one finger's breadth outside the nipple line; the action was regular and of good force. Over the second intercostal space, and to the right of the sternum, was heard a loud, rough systolic murmur which was transmitted into the vessels of the neck and down along the sternum. This murmur was also heard over the pulmonic area. The *x*-ray showed the right and left borders of the heart displaced to the right, and it gave the impression of the heart being rotated. There was a distinct dilatation of the aortic arch. The physical examination showed small blood-vessels, with an enlargement of the aortic arch easily mapped out. The pulsation and thrill could be readily felt in the episternal notch. The case was one of congenital narrowing of the aortic isthmus.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Wisconsin Board of Medical Examiners.

January 10 *to* 12, 1911.

PATHOLOGY, HISTOLOGY, BACTERIOLOGY.

1. Name the degenerative or retrogressive processes and describe the microscopic appearances of two of them.
2. Name the causes of infarction and give the pathology of their termination.
3. Give the causes of arterosclerosis and the pathological histology of same.
4. How many and what are the varieties of cirrhosis of the liver?
Give etiology of each, and describe the pathological histology of one variety.
5. Give etiology of tuberculosis, discuss sources of contagion and route of entrance to the tissues of the body. Describe a typical tubercle.
6. Give causes of endocarditis and describe the pathological histology of endocardial vegetations.
7. Name the organs of the body most prone to cancer in order of the frequency of their involvement. Classify the tumors of epithelial origin.
8. What is anemia? Give varieties, differentiate lymphatic leukemia and splenomedullary leukemia.
9. What diseases due to bacteria show a bacteriemia? Give the pathology of typhoid fever.
10. How would you prove that bacteria cause disease.
11. Give the normal histology of the skin.
12. Give the normal histology of a nerve, a muscle, an artery.

ANATOMY.

1. Describe the fifth cranial nerve.
2. Describe the femoral vein.
3. Describe the spleen.
4. Describe the fourth ventricle, and where is it located?
5. Give the boundaries of the axillary space, and name its contents.
6. Describe the abdomen, and name its contents.
7. Describe the pancreas.
8. Describe the biceps and triceps muscles.

PEDIATRICS.

1. Differentiate spasmodic laryngitis and membranous croup, and give treatment of the latter.
2. Give three causes of convulsions in children, and treatment.
3. Describe fully the general management of a case of scarlet fever.
4. Differentiate catarrhal from lobar pneumonia.

PRINCIPLES AND PRACTICE.

1. Give the diagnosis of typhoid fever.
2. Name six organic diseases of the heart and give the physical signs in three of them.
3. Give the treatment of acute and chronic bronchitis.
4. Give the diagnosis and treatment of enterocolitis in children.
5. Give differential diagnosis of smallpox and chickenpox.
6. Give diagnosis of tabes dorsalis.
7. What are the complications of acute articular rheumatism and what are the best means of preventing them?
8. Give diagnosis and treatment of acute lobar pneumonia in the first stage.

MATERIA MEDICA AND THERAPEUTICS.

1. Give physiological actions and uses of strychnine.
2. Name five preparations of mercury with the doses of each.
3. Give the physiological actions of ergot.
4. Give treatment of poisoning by carbolic acid.
5. What do you consider the safest general anesthetic and what is your method of its administration?
6. Give the first signs of danger in giving a general anesthetic?
7. Give means of resuscitation in threatened death from anesthesia.

PHYSIOLOGY, OPHTHALMOLOGY AND LARYNGOLOGY.

1. Describe the nervous mechanism of muscular contraction.
2. What is food? Classify and give functions.
3. Differentiate between serous, mucous, and synovial membranes. Tell where each is found.
4. How is asphyxia produced? What are the causes of death from asphyxia?
5. Describe the physiology of hearing.
6. Name the organs of elimination and tell what is eliminated by each.
7. Give the distribution and function of the third and fifth cranial nerves.
8. Define respiration, its purpose and how accomplished. Define a reflex arc.
9. Give cause, diagnosis and treatment of corneal ulcer.
10. What is choked disc? Give most important cause and treatment.
11. Diagnose and give treatment for foreign bodies in the larynx.
12. Give etiology and diagnosis of atrophic rhinitis. How is it cured?

OBSTETRICS.

1. At what time during pregnancy is an abortion most dangerous? Describe the management of such a case.
2. Give etiology and treatment of pernicious vomiting of pregnancy.
3. What symptoms during pregnancy would cause you to fear postpartum hemorrhage, and what treatment would you use to prevent its occurrence?
4. What treatment would you use to prevent toxemia of pregnancy?
5. Give diagnosis and management of breech presentation and cause of fetal mortality incident to same.
6. What are the indications for the use of forceps? Give rule for applying them.
7. If the conditions were such that you feared laceration of the cervix, what means would you use to prevent the same?
8. State fully your treatment of puerperal convulsions during and after labor.

GYNECOLOGY.

1. Give symptoms and treatment of cervical endometritis.
2. Name the ligaments that hold the uterus in position and give attachments of same.
3. Name the number of and different places at which a pelvic abscess may "point."
4. Give general outline of treatment for disturbances and disorders incident to the menepaus.

SURGERY.

1. Name and define the three most important principles of practice in present-day surgery.
2. Name and define anesthetics in the order of frequency used, and give contraindications for use of each.
3. Give diagnosis and treatment of a ruptured male urethra.
4. Give indications for tracheotomy in the order of frequency required, and define the operation.
5. Give diagnosis and treatment of a ruptured appendix vermiformis.
6. Give diagnosis and treatment of a cholecystitis with obstruction.
7. Give treatment for fracture of both bones of the forearm at or near their middle.
8. Give treatment for dislocation of outer end of clavicle.

PHYSICAL DIAGNOSIS.

1. Give the physical signs of lobular pneumonia.
2. Give physical signs of empyema of chest.
3. Give physical signs of cardiac dilatation.

HYGIENE.

1. Give amount of fresh air space necessary to each individual in the sick room.
2. Give amount of excrement exhaled from lungs and excreted from the skin in twenty-four hours and the best methods of disposal.

NEUROLOGY, MEDICAL JURISPRUDENCE AND DIETETICS.

1. Name all the nerves that would be severed in an amputation of the arm, at the junction of the middle with the upper third.
2. Give origin, distribution and function of any one of the cranial nerves, and name its foramen of exit from the skull.
3. Name and locate the principal parts of the primary divisions of the cerebro-spinal nervous system.
4. (a) What is the "Romberg symptom?"
(b) Name and describe the various stages of the disease in which it occurs.
5. Give the nerve supply of the stomach, liver, spleen, and diaphragm.
6. In a case of supposed infanticide, what post-mortem signs would determine whether the babe was born dead or alive?
7. Can a physician be held liable to a charity patient, in case malpractice is proven against him?
8. Can a master, who calls a physician to attend to a servant in his employ, be held for the physician's fee?
9. What is the advantage of toast over ordinary bread in certain gastric disturbances?
10. What constitutes good drinking water?
11. At about what age would you begin to feed a child farinaceous foods? nitrogenous foods?
12. Name the foods which may be permitted, and those which should be forbidden in the treatment of diabetes mellitus.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

WISCONSIN BOARD OF MEDICAL EXAMINERS.

January 10 *to* 12, 1911.

PATHOLOGY, HISTOLOGY, BACTERIOLOGY.

1. The *degenerative or retrogressive processes* are: Atrophy, cloudy swelling, fatty degeneration, fatty infiltration, albuminoid degeneration, amyloid degeneration, hyaline degeneration, mucoid degeneration, colloid degeneration, glycogenic infiltration, dropsical infiltration, calcification, ossification, necrosis, pigmentation, gangrene, and inflammation. For microscopic appearances of two see French's "Practice of Medicine" (1910), pages 31, etc.
2. See French's "Practice of Medicine" (1010), page 28.
3. See French's "Practice of Medicine" (1910), page 640; or Osler's "Practice of Medicine" (1909), page 848.
4. See French's "Practice of Medicine" (1910), page 842; or Osler's "Practice of Medicine" (1909), page 556.
In *atrophic cirrhosis:* The liver is shrunken and indurated, rough, and of a pale or yellow color; a growth of new connective tissue is disposed in broad bands which run in various directions, and by their contraction divide the liver into numerous irregular lobes. Many acini may be affected at one time. The capsule may be thickened, or adherent to the diaphragm. Jaundice is slight, and comes on late; ascites is pronounced and may occur early.
5. See French's "Practice of Medicine" (1910), pages 333 to 344; or Osler's "Practice of Medicine" (1909), pages 284 to 296.
6. ACUTE ENDOCARDITIS. *Etiology:* Microorganisms (chiefly *Staphylococcus pyogenes aureus, Streptococcus pyogenes, Diplococcus pneumoniæ,* gonococcus, and others); acute articular rheumatism, pneumonia, scarlet fever, puerperal sepsis, nephritis, etc., are said to be etiological factors. *Pathology:* The valves (mitral, aortic, and pulmonary), and endocardium of ventricles and left auricle are chiefly involved. The valves are affected on a line very near to the free edge; the chordæ tendineæ also suffer, and the endocardium of the left ventricle, near the septum. Opacity, roughness, nodular elevations, fibrous deposit, ulceration have all been observed. *Results:* Calcification, destruction of chordæ tendineæ or valve, myocarditis pericarditis, embolism, infarcts or metastatic abscesses in spleen, brain, or kidneys.
And see French's "Practice of Medicine" (1910), page 578; or Osler's "Practice of Medicine" (1909), page 786.
7. *Scirrhous carcinoma* occurs in: Female breast, stomach, esophagus, bladder, rectum, and skin. *Colloid carcinoma* in: Stomach, intestines, and female breast. *Cylindrical celled carcinoma,* in: Rectum, uterus, bladder, superior maxilla, and stomach.
EPITHELIAL TUMORS are: (*a*) *Benign:* Adenoma and papilloma; (*b*) *Malignant:* Epithelioma, rodent ulcer and carcinoma.
8. *Anemia* is a condition characterized by a diminution in the number of red-blood cells, or of hemoglobin, or of both.
Varieties: (1) Local.
(2) General { Primary { Chlorosis. / Secondary { Pernicious anemia.
See French's "Practice of Medicine" (1910), pages 529 and 530; or Osler's "Practice of Medicine" (1909), pages 734 and 736.
9. *Bactericmia* is found in: Pneumonia, typhoid, anthrax, pyemia, gonorrhea, syphilis.
For pathology of typhoid fever see French's "Practice of Medicine" (1910), page 70; or Osler's "Practice of Medicine" (1909), page 65.
10. To *prove that bacteria cause disease* it is essential: (1) That the microorganism be found in the tissues, blood, or secretions of a person or animal sick or dead of the disease; (2) the microorganism must be isolated and cultivated from these same sources; it must also be grown for several generations in artificial culture media; (3) the pure cultures, when thus obtained, must, on inoculation into a healthy and susceptible animal, produce the diseases in question, and (4) the same microorganisms must again be found in the tissues, blood, or secretions of the inoculated animal.
11. See Cunningham's "Anatomy" (1909), page 773; or Gray's "Anatomy" (1908), page 1190.
12. See Cunningham's "Anatomy" (1909), pages 445, 317, and 781; or Gray's "Anatomy" (1908), pages 820, 364, and 587.

ANATOMY.

1. See Cunningham's "Anatomy" (1909), page 678; or Gray's "Anatomy" (1908), page 1041.
2. See Cunningham's "Anatomy" (1909), page 898; or Gray's "Anatomy" (1908), page 758.
3. See Cunningham's "Anatomy" (1909), page 1210; or Gray's "Anatomy" (1908), page 1361.
4. See Cunningham's "Anatomy" (1909), page 487; or Gray's "Anatomy" (1908), page 878.
5. The axillary space is *bounded: Anteriorly,* by the clavicle, Subclavius, Pectoralis major, costocoracoid membrane, Pectoralis minor; *posteriorly,* by the Subscapularis, Teres major, and Latissimus dorsi; *internally,* by the first four ribs, first three Intercostal muscles, Serratus magnus; *externally,* by the humerus, Coracobrachialis, and Biceps.
Contents: The axillary vessels and brachial plexus of nerves, with their branches, some branches of the intercostal nerves, and a large number of lymphatic glands, all connected together by a quantity of fat and loose areolar tissue.
6. See Cunningham's "Anatomy" (1909), pages 1043 and 1047; or Gray's "Anatomy" (1908), pages 1241 and 1244.
7. See Cunningham's "Anatomy" (1909), page 1124; or Gray's "Anatomy" (1908), page 1355.
8. See Cunningham's "Anatomy" (1909), pages 332, 368, and 335; or Gray's "Anatomy" (1908), pages 477, 532, and 479.

PEDIATRICS.

1. Membranous croup is laryngeal diphtheria. See French's "Practice of Medicine" (1910), pages 663, 188, and 195; or Osler's "Practice of Medicine" (1909), pages 599, 202, and 207.
3. See French's "Practice of Medicine" (1910), page 324;
2. See French's "Practice of Medicine" (1910), page 1159; or Osler's "Practice of Medeicine" (1909), page 1056, or Osler's "Practice of Medicine" (1909), page 138.
4.

LOBAR PNEUMONIA.	CATARRHAL PNEUMONIA.
Generally a primary disease.	Generally secondary (to bronchitis or an infectious disease).
Age has little influence.	Generally found in very young or very old.
Sudden onset.	Gradual onset.
Fever is high and regular.	Fever is not so high, and is irregular.
Ends by crisis between sixth and tenth day.	Ends by lysis, at no particular date.

LOBAR PNEUMONIA.	CATARRHAL PNEUMONIA.
Generally only one lung affected.	Generally both lungs affected.
The physical signs are distinct; and there is a large area of consolidation.	Physical signs indistinct; and the evidences of consolidation are indefinite.
Sputum is rusty.	Sputum is rather streaked with blood.

PRINCIPLES AND PRACTICE.

1. See French's "Practice of Medicine" (1910), page 101; or Osler's "Practice of Medicine" (1909), page 93.

2. Mitral regurgitation, mitral stenosis, aortic regurgitation, aortic stenosis, tricuspid regurgitation, tricuspid stenosis; and see French's "Practice of Medicine" (1910), pages 590, 600, and 603; or Osler's "Practice of Medicine" (1909), pages 800, 803, and 806.

3. See French's "Practice of Medicine" (1910), pages 666 and 669; or Osler's "Practice of Medicine" (1909), pages 603 and 605.

4. See French's "Practice of Medicine" (1910), page 803; or Osler's "Practice of Medicine" (1909), page 501.

5. *Varicella* is chickenpox; *variola* is smallpox.

(1) Very young children are attacked with varicella, whereas variola usually shows itself in adults. (2) Vaccinated children readily take varicella; not so variola, even in the modified form. (3) Children who have had varicella may contract variola, even soon afterward; or the two diseases may coexist. (4) Varicella is not inoculable, whereas variola is notoriously so. (5) The eruption of varicella appears in twenty-four hours; that of variola not till the third day. (6) The febrile symptoms continue after the eruption appears in varicella; those of variola subside. (7) In varicella the spots come out in successive crops; this is never seen in variola. (8) The spots in varicella are unilocular, and collapse on being punctured; the spots in variola are multilocular, and do not collapse on being punctured. (9) In varicella the eruption is very irregular, and appears over the body generally; in variola it appears in groups of threes and fives, and is always seen on the limbs. (10) The papule in varicella is soft, and disappears on stretching the skin; in variola it is hard and shotty, and does not disappear on stretching the skin.

7. See French's "Practice of Medicine" (1910), pages 226 and 230; or Osler's "Practice of Medicine" (1909), pages 223 and 226.

8. See French's "Practice of Medicine" (1910), pages 156, 171 and 174; or Osler's "Practice of Medicine" (1909), pages 172, 175, and 189.

MATERIA MEDICA AND THERAPEUTICS.

1. STRYCHNINE. *Action:* Strychnine is a bitter tonic, stimulates appetite, secretion, and digestion, increases peristalsis, stimulates the vasomotor centers, and so raises arterial tension; it stimulates both accelerator and inhibitory nerves of the heart. All the functions of the spinal cord are exalted by strychnine, reflex, motor, vasomotor, and sensory. Large doses cause dilated pupils, irregular and jerky respiration, increased reflexes. *Therapeutic uses:* For indigestion, intestinal torpor, heart disease, pneumonia, amenorrhea, dysmenorrhea, paralysis, impotence, and as a cardiac and respiratory stimulant.

2. Hydrargyrum cum creta, gr. iv; massa hydrargyri, gr. iv; hydrargyri chloridum mite, gr. j; liquor arseni et hydrargyri iodidi, ℥jss; hydrargyri chloridum corrosivum, gr. 1/20.

3. ERGOT. *Physiological action:* Ergot stimulates and causes contraction of involuntary muscle fibers, hence it is a vasoconstrictor, hemostatic, and oxytocic. It is also a cardiac sedative, it raises the blood pressure, it increases peristalsis, and is an emmenagogue.

4. Give any soluble sulphate, such as sodium sulphate, or alcohol. The stomach may be washed out with equal parts of alcohol and water, and about half a pint of the same mixture may be left in the stomach.

5. The safest general anesthetic is, undoubtedly, nitrous oxide; see Da Costa's "Surgery" (1908), page 1044.

6 and 7. See Rose and Carless' "Surgery" (1908), page 1325; or Da Costa's "Surgery" (1908), page 1035.

PHYSIOLOGY, OPHTHALMOLOGY, AND LARYNGOLOGY.

1. The impulse causing ordinary muscular contractions originates in the centers of the brain or spinal cord, and then travels by the nerves going to the particular muscles. As such nerve enters a muscle it breaks up into a number of branches, which are distributed to all parts of the muscle. The terminal ends of the nerve are scattered in great numbers throughout the muscle, and the impulse carried by the nerve is transmitted by the end plates to the various muscle fibers. Sometimes the muscular contraction may be reflex. (See below, Question 8.)

2. *Food* is material which, after being taken into the body, is capable of building up the body, of repairing tissue waste, and of supplying heat and energy. *Foods are classified* as:

I. Inorganic.. { Water; Salts.

II. Organic.... { Nitrogenous—Proteids. / Non-Nitrogenous. } Carbohydrates. / Fats.

Function of proteids: Formation and repair of tissues and fluids of the body, regulation of the absorption and utilization of oxygen, formation of fats and carbohydrates, production of energy. *Function of carbohydrates:* Production of heat and energy and formation of fats. *Function of fats:* Supply of heat and energy, supply of fatty tissues, nutrition of nervous system. *Function of salts:* Support of bony skeleton, supply of HCl for digestion, regulation of nutrition and energy. *Function of water:* It enters into the composition of all the tissues and fluids of the body, it moistens the surfaces and membranes of the body, it keeps the fluids of the body at their proper degree of dilution, it removes waste matters, distributes and regulates body heat.

3. *Mucous membrane* lines those parts which communicate with the exterior of the body; it contains glands, basement membrane, connective tissue support, blood and nerve supply, and epithelium. *Found* in digestive, respiratory, and genitourinary tracts.

Serous membrane lines closed cavities (except peritoneum in the female); it contains a basement membrane and endothelial cells, but no glands. *Examples:* Pericardium, pleura, peritoneum, tunica vaginalis of testis, and meninges.

Synovial membrane is in connection with joint and tendons, and has no glands, but a basement membrane with connective tissue cells.

4. Asphyxia is suffocation, due to depriving the lungs of oxygen. It is caused by preventing oxygen from reaching the lungs; by obstruction of the respiratory passages; by inhaling a gas without oxygen, or one which strongly tends to displace oxygen from the hemoglobin, as carbon monoxide; or by interfering with the change of gases which should take place between the air and the blood.

The cause of death in asphyxia is: Paralysis of the respiratory center in the medulla.

5. "The waves of sound are gathered together by the pinna and external auditory meatus, and conveyed to the membrana tympani. This membrane, made tense or lax by the action of the tensor tympani and laxator tympani muscles, is enabled to receive sound waves of either high or low pitch. The vibrations are conducted across the middle ear by a chain of bones to the foramen ovale, and by the column of air of the tympanum to the foramen rotundum, which is closed by the second membrana tympani, the pressure of the air in the tympanum being regulated by the Eustachian tube. The internal ear finally receives the vibrations, which excite vibrations successively in the perilymph, the walls of the membranous labyrinth, the endolymph, and, lastly, the terminal filaments of the auditory nerve, by which they are conveyed to the brain."—(Brubaker's *Physiology.*)

6. The *organs of elimination*, are: (1) The *skin*, which eliminates water and a slight quantity of carbon dioxide, urea, and salts; (2) the *lungs*, which eliminate water, carbon dioxide; (3) the *intestines*, which eliminate the indigestible and unabsorbed substances from the food, with secretions from liver and pancreas; (4) the *kidneys*, which eliminate water, urea, other nitrogenous matter, and salts.

7. The third cranial nerve is the motor nerve to all the muscles of the orbit except the Superior oblique and the External rectus. Hence, it supplies the Rectus superior, Rectus inferior, Rectus internus, Inferior oblique, and Levator palpebræ superioris. It also (through the ciliary ganglion) supplies the sphincter muscle of the iris, and the ciliary muscle.

7. THE FUNCTIONS OF THE FIFTH CRANIAL NERVE. *First ophthalmic branch* supplies sensation to conjunctiva and skin of upper eyelid, cornea, skin of forehead and nose, lachrymal glands, mucous membrane of nose. *Second, or superior, maxillary branch* supplies sensation to skin and conjunctiva of lower lid, nose, cheek, upper lip, upper teeth and alveolar processes, and palate. *Third, or inferior, maxillary branch* supplies sensation to external auditory meatus, side of head, mucous membrane of mouth, anterior two-thirds of tongue, lower teeth, lower lip, and skin of the lower part of the face. This branch, in addition, supplies motion to the muscles of mastication (Masseter, Temporal, External, Pterygoid, Internal Pterygoid), also mylohyoid and anterior belly of digastric.

8. Respiration is the act of breathing; it includes both inspiration and expiration. Its purpose is to introduce oxygen into the system and to excrete carbon dioxide. And see Cunningham's "Anatomy" (1909), page 419.

Reflex actions are involuntary or unconscious movements, due to suitable stimuli. They depend upon the integrity of the *reflex arc*, which is a complex made up of: (1) A surface capable of receiving an impression: (2) an afferent nerve; (3) a nerve cell capable of receiving and also of sending out impulses; (4) an efferent nerve and (5) a surface capable of responding in some way to the impulse conveyed by the efferent nerve.

9. "*Corneal ulcer* results from traumatism or extension of inflammation from some adjoining tissue. It is detected by oblique illumination, the ophthalmoscope, or convex lens, and by dropping fluorescin upon the cornea, the denuded area being colored green. Pain, photophobia, lacrimation, swelling of the lids and conjunctiva, and destruction of tissue are symptoms. Corneal opacities, staphyloma, perforation, adherent leukoma, atrophy of the eyeball, and prolapse of the lens and vitreous may result. The treatment consists in putting the eye at rest, instilling atropine, and the application of a bandage. Leeches to the temple will relieve the pain. Hot compresses have the same effect. The eye should be douched with sublimate solution, 1:5000, and iodoform dusted upon the cornea. Stronger sublimate solution, boroglycerid 50% and formalin 10%, are sometimes necessary. Cauterization is occasionally indicated. If perforation seems probable it should be hastened by a puncture." (Gould and Pyle's *Pocket Cyclopedia.*)

10. *Choked disc* is a condition in which the optic papilla is swollen, congested, and inflamed; it is due to increased intracranial pressure.

It occurs in brain tumors, tuberculous meningitis, abscess of the brain, syphilis, nephritis, rheumatism, toxic agents (as lead or alcohol), infectious diseases, and anemia. Treatment consists in removing the cause.

11. See Rose and Carless' "Surgery" (1908), page 905; or Da Costa's "Surgery" (1908), page 767.

12. See Rose and Carless' "Surgery" (1008), page 829.

OBSTETRICS.

1. Abortion is most dangerous in the *later* months of pregnancy.

See Williams' "Obstetrics" (1909), page 618; or Hirst's "Obstetrics" (1909), page 279.

2. See Williams' "Obstetrics" (1909), pages 509 and 515; or Hirst's "Obstetrics" (1909), pages 238 and 239.

3. There are no particular symptoms during pregnancy that would lead one to fear postpartum hemorrhage.

4. See Williams' "Obstetrics" (1909), page 519; or Hirst's "Obstetrics" (1909), pages 239 and 249.

5. See Williams' "Obstetrics" (1909), pages 285 and 289; or Hirst's "Obstetrics" (1909), pages 419 and 424.

6. *Indicotions for the use of forceps are:* (1) *Forces at fault:* Inertia uteri in the presence of conditions likely to jeopardize the interests of mother or child. (*a*) Impending exhaustion; (*b*) arrest of head, from feeble pains. (2) *Passages at fault:* Moderate narrowing, 3¼ to 3¾ inches, true conjugate; moderate obstruction in the soft parts. (3) *Passenger at fault:* A. Dystocia due to (*a*) occipito-posterior; (*b*) mentoanterior face; (*c*) breech arrested in cavity. B. Evidence of fetal exhaustion (pulse above 160 or below 100 per minute). (4) *Accidental complications:* Hemorrhage; prolapse funis; eclampsia. All acute or chronic diseases or complications in which immediate delivery is required in the interest of mother or child, or both. *Contraindications:* Mechanical obstruction in the parturient canal; incomplete dilatation of the os; nonrupture of membranes; non-engagement of the presenting part; the fetal head being too large or too small; distended bladder or rectum.

For application, see Williams' "Obstetrics" (1909), page 400; or Hirst's "Obstetrics" (1909), page 811.

7. Particular care must be taken in any operative procedure.

8. See Williams' "Obstetrics" (1909), page 541; or Hirst's "Obstetrics" (1909), page 635.

GYNECOLOGY.

1. *Cervical endometritis* is "usually secondary to some impairment of the general health or to displacements of the uterus, laceration of the cervix, and gonorrhea. The symptoms are headache, backache, pain in pelvis, and the presence of characteristic, whitish, opaque, thick, and tenacious discharge. A possible cause should be sought for and corrected. The general health will be improved by the administration of preparations containing iron, such as Blaud's pill, Basham's mixture, and the 4 chlorides. Exercise, diet, and the condition of the bowels should receive attention. The local treatment consists in the administration of hot vaginal douches 2 or 3 times daily; the use of glycerine tampons for 12 hours, twice a week; the application of tincture of iodine to the cervix, once a week; and the application of silver nitrate, zinc chloride, pure carbolic acid, or Churchill's tincture of iodine directly to the cervical mucous membrane." (Gould and Pyle's *Pocket Cyclopedia.*)

2. The LIGAMENTS OF THE UTERUS are: (1) *Broad ligaments*, which extend outward on each side from the side of the uterus to the side of pelvis. (2) *Rectouterine ligaments*, which extend backward from the intraperitoneal potrion of the cervix uteri to the peritoneal investment of the rectum. (3) *Round ligaments*, which extend from the uterus just below the Fallopian tubes, through the inguinal canal to the labia majora. (4) The *ovarian ligaments*, which extend from the superior part of the uterus, behind the Fallopian tubes, to the inner end of the ovary. (5) The *uterosacral ligaments*, which extend from the highest part of the cervix uteri to the sides of the sacrum opposite the lower border of the sacroiliac synchondrosis.

3. "The pus in a pelvic abcess points and escapes in one of many situations. The abscess may open into the mucous canals of the pelvis—rectum, vagina, or even the bladder. It may point in the groin, immediately above or below Poupart's ligament; the pus will sometimes burrow beneath the fascia lata, and point in the middle of the thigh, usually on the outer side. Occasionally it travels by the side of the urachus and points at the navel; exceptionally it will burrow through the great sciatic notch and gain the buttock." (Sutton and Giles' *Diseases of Women.*)

4. *General outline of treatment for diseases and disturbances of the menopause:* "This must be directed to regulating the secretions. Generally constipation, previously troublesome, becomes aggravated, and portal congestion frequently occurs. Saline purgatives are especially beneficial, and these may be judiciously administered in the form of mineral waters, such as the Hunyadi Jànos or Friedrichshall. Blue pill with aloes is often very useful. The headaches and reflex nervous symptoms may be best combated by the administration of bromide of potassium, and this drug appears to act as a direct sedative to the sexual organs, besides diminishing the amount of blood determined to them. Occasionally bleeding from the arm or cupping gives great relief. Attention must, above all, be paid to the diet. It should be plain and unstimulating; beer and spirits should be prohibited, and only light wines, if any, allowed. Tepid baths are useful. Late hours, heated rooms, and excitement of all kinds should be avoided. If local troubles arise they must be treated according to their indications. It is clearly impossible to map out any empirical line of treatment for a condition in which the symptoms are so variable."—(Quain's *Dictionary of Medicine.*)

SURGERY.

1. Asepsis, antisepsis, and anesthesia. See Rose and Carless' "Surgery" (1908), pages 266, 264, and 1318; or Da Costa's "Surgery" (1908), pages 50 and 1025.

2. See Rose and Carless' "Surgery" (1908), page 1318; or Da Costa's "Surgery" (1908), page 1025.

The order of frequency is ether and chloroform for general anesthesia, and cocaine first for local anesthesia.

Chloroform is a colorless liquid of sweetish, peculiar odor and taste, with anesthetic properties. Chemically it is trichlormethane. *Ether* is a colorless liquid, of peculiar odor and taste, with anesthetic properties. Chemically it is ethyl oxide. As a general rule, ether would be the anesthetic of choice. But chloroform may be used: (1) In hot climates; (2) when large numbers of persons have to be rapidly anesthetized; (3) in brain surgery; (4) in labor; (5) in patients who are known to take ether badly; and (6) in the conditions mentioned below, in which ether is contraindicated. The following *contraindications* for ether and chloroform are from Hare's "Practical Therapeutics": "*Ether* should not be used by inhalation in bronchitis or acute nephritis because of its irritant properties; in peritonitis or gastritis, because it is apt to induce vomiting; in aneurysm or in the presence of marked vascular atheroma because it may rupture a blood-vessel by raising arterial pressure; nor in diabetes, lest it produce diabetic coma; and if anemia is present and an examination of the blood shows that the hemoglobin is below 50 per cent., the use of the drug should be avoided if possible. *Chloroform* is not to be used in cases of fatty heart or dilatation of the heart, in those with a known idiosyncrasy, nor in the so-called lymphatic persons with overgrowth of lymphoid tissues, as, for example, adenoids. In the latter case it is particularly apt to cause sudden death. In valvular disease of the heart chloroform may

le used with caution, although ether is preferable. Given a case of valvular disease that must be subjected to operation, the chances are bettered with an anesthetic than without it, as the pain and mental shock are worse for the heart than is the anesthetic."

3. See Rose and Carless' "Surgery" (1908), page 1232; or Da Costa's "Surgery" (1908), page 1151.

4. See Rose and Carless' "Surgery" (1908), page 914

5. See Rose and Carless' "Surgery" (1908), pages 1030, 1043, and 1050; or Da Costa's "Surgery" (1908), page 868.

6. See Rose and Carless' "Surgery" (1908), pages 1059, 1060, and 1061; or Da Costa's "Surgery" (1908), page 891.

7. See Rose and Carless' "Surgery" (1908), page 526; or Da Costa's "Surgery" (1908), page 505.

8. See Rose and Carless' "Surgery" (1908), page 619; or Da Costa's "Surgery" (1908), page 586.

PHYSICAL DIAGNOSIS.

1. See French's "Practice of Medicine" (1910), page 689; or Osler's "Practice of Medicine" (1909), page 625.

2. See French's "Practice of Medicine" (1910), page 712; or Osler's "Practice of Medicine" (1909), page 649.

3. See French's "Practice of Medicine" (1910), page 617; or Osler's "Practice of Medicine" (1909), page 827.

HYGIENE.

1. Each individual in the sick room should have 1,500 cubic feet of air space; this, allowing for the air to be changed three times in an hour, will allow 4,500 cubic feet of fresh air per hour.

2. Excrement exhaled from *lungs* per day is about 220 to 250 grams of carbon and about 330 grams of water; by the *skin,* about 2 grams of carbon, 650 grams of water, and various salts.

Assuming that the latter part of the question is correctly printed, proper ventilation and ample bathing should be provided for.

NEUROLOGY, MEDICAL JURISPRUDENCE, AND DIETETICS.

1. The median, ulnar, musculospiral, internal cutaneous, and musculocutaneous nerves.

2. THIRD CRANIAL NERVE. *Origin:* Inner side of the crus cerebri, in front of pons Varolii, and (deep origin) from the floor of the aqueduct of Sylvius. *Distribution and function:* See PHYSIOLOGY, 7. It leaves the skull through the sphenoidal fissure.

3. See Cunningham's "Anatomy" (1909), page 443; or Gray's "Anatomy" (1908), page 804.

4. See French's "Practice of Medicine" (1910), page 1085; or Osler's "Practice of Medicine" (1909), page 890.

5. NERVE SUPPLY. Of *stomach:* Right and left pneumogastrics and solar plexus of the sympathetic; of *liver:* Left pneumogastric and solar plexus; of *spleen:* Splenic plexus (from solar plexus); of *diaphragm:* Phrenics, lower intercostals, and phrenic plexus (of sympathetic).

6. If respiration has taken place, the lungs will float on being put into water; if respiration has not taken place, the lungs will sink. Further, the lungs before respiration are situated at the back of the thorax and do not fill the cavity; whereas, after respiration, they fill the whole cavity.

7. Certainly, the physician is liable; the receiving of a fee does not enter into the question of malpractice.

8. The master cannot be held liable for the physician's fee unless he (the master) made a specific contract to pay the same.

9. Toast is more digestible

10. *Characteristics of a good drinking water:* (1) It should be clear and limpid. Cloudy and muddy waters should be avoided. (2) It should be colorless. A greenish or yellowish color is usually due to vegetable or animal matter in solution or to organisms. (3) It should be odorless; especially free from sulphuretted hydrogen or putrefactive animal matter. (4) It should not be too cold, but should have a temperature of from 46° F. to 60° F. (5) It should have an agreeable taste; neither flat, salty, nor sweetish. A certain amount of hardness and dissolved gases give a sparkling taste. It should contain from 25 to 50 c.c. of gases per liter, of which 8 to 10 per cent. is carbon dioxide and the rest oxygen and nitrogen. (6) It should be as free as possible from dissolved organic matter, especially of animal origin. (7) It should not contain too great an amount of hardness. A certain quantity of saline matter is necessary, however, to give it a good taste. It should not contain over three or four parts of chlorine in 100,000 parts of water.—(From Bartley's *Chemistry.*)

11. Farinaceous foods should not be given to a child of less than nine months old; meat may be gradually introduced into the dietary in from three to six months later.

It is not clear what is meant by *nitrogenous food;* milk contains proteid (which is nitrogenous).

12. See French's "Practice of Medicine" (1910), page 974; or Osler's "Practice of Medicine" (1909), page 420.

BULLETIN OF APPROACHING EXAMINATIONS.

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†
Alabama*	W. H. Sanders, Montgomery	Montgomery...July 11
Arizona*	Ancil Martin, Phoenix	Phoenix July 3
Arkansas	F. T. Murphy, Brinkley	Little Rock May 9
California*	Chas. L. Tisdale, 929 Butler Building, San Francisco	San Francisco Aug. 1
Colorado	S. D. Van Meter, 1723 Tremont Street, Denver	Denver July 4
Connecticut*	Chas. A. Tuttle, New Haven	New Haven July 11
Delaware	J. H. Wilson, Dover	Dover June 20
Dist. of Col'ba	Geo. C. Ober, Washington	Washington April 11
Florida*	I. D. Fernandez, Jacksonville	Tallahassee May 3
Georgia	T. H. Goss, Athens	Atlanta May —
Idaho*	O. J. Allen, Bellevue	Boise Oct. 3
Illinois	J. A. Egan, Springfield	Chicago
Indiana	W. T. Gott, Crawfordsville	Indianapolis July 11
Iowa	G. H. Sumner, Des Moines	Iowa City June —
Kansas	H. A. Dykes, Lebanon	Kansas City June 13
Kentucky	J. N. McCormack Bowling Green	
Louisiana	A. B. Brown, 108 Baronne St	New Orleans May 18
Maine	F. W. Searle, Portland	Augusta July 6
Maryland	J. McP. Scott, Hagerstown	Baltimore June 20
Massachusetts*	E. B. Harvey, State House, Boston	Boston May 9
Michigan	B. D. Harrison, 205 Whitney Building, Detroit	Ann Arbor June 13
Minnesota	W. S. Fullerton, St. Paul	
Mississippi	S. H. McLean, Jackson	Jackson. May 9
Missouri	Frank B. Hiller, Jefferson City	
Montana*	Wm. C. Riddell, Helena	Helena Oct. 3
Nebraska	E. A. Carr, Lincoln	Lincoln May 10
Nevada	S. L. Lee, Carson City	Carson City May 1
N. Hampshire	Henry C. Morrison, State Library, Concord	Concord July 6
New Jersey	H. G. Norton, Trenton	Trenton June 20
New Mexico	J. A. Massie, Santa Fe	Santa Fe April 10
New York	C. F. Wheelock, Univ. of State of New York, Albany	Albany, Syracuse, Buffalo, New York May 23
N. Carolina	B. K. Hays, Oxford	Charlotte June 14
N. Dakota	H. M. Wheeler, Grand Forks	Grand Forks July 4
Ohio	Geo. H. Matson, Columbus	Columbus June —
Oklahoma*	F. P. Davis, Enid	Oklahoma April 11
Oregon	B. E. Miller, Portland	Portland July 3
Pennsylvania*	A. R. Allen, Carlisle	Philadelphia, Pittsburg June 27
Rhode Island	G. T. Swarts, Providence	Providence July 6
S. Carolina	H. H. Wyman, Aiken	Columbus June 13
S. Dakota	F. W. Preyberg, Mitchell	Pierre July 12
Tennessee	C. A. Abernathy, Pulaski	Memphis, Nashville, Knoxville May —
Texas	J. D. Mitchell, Fort Worth	Austin June 26
Utah	R. W. Fisher, Salt Lake City	Salt Lake City July 3
Vermont	W. Scott Nay, Underhill	Montpelier July 11
Virginia	R. S. Martin, Stuart	Richmond June 21
Washington*	F. P. Witter, Spokane	Tacoma July 4
W. Virginia	H. A. Barbee, Point Pleasant	Huntington April 10
Wisconsin	J. M. Beffel, Milwaukee	Madison July 11
Wyoming	S. B. Miller, Laramie	

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

New York.—At the recent examination a change was instituted which will make the examination a much more severe test than heretofore. Instead of having to select *any ten* questions out of the fifteen offered, the candidate has to take the *first six*, and then select any four out of the remaining nine. This will tend to put New York in line with the States having the most severe tests.

Mississippi.—At the last examination there were 70 applicants, but only 26 passed.

Washington.—At the January examination there were 75 candidates; of this number 51 passed and were licensed to practise medicine in that State.

Massachusetts.—During the year 1910 270 persons applied to the board for registration; all but one were examined. Two hundred and forty-six of these were school graduates, of whom 202 passed and were registered; 44 were rejected. Of the 23 undergraduates who applied, 6 passed and were registered, 17 being rejected.

Washington.—At the January examination there were 75 candidates, of whom 51 passed and 24 failed.

Vaccine Treatment of Tuberculosis.—H. Batty Shaw believes that treatment with tuberculin of cases of pulmonary tuberculosis has not yet been satisfactorily proved to be efficacious. What is needed is a rigorous proof by animal experiments that an infection once initiated can be overcome by the use of tuberculin, and then before these results can be applied in treatment more definite facts must be obtained of the proportion of affected human beings who are capable, without external aid, of overcoming pulmonary tuberculosis. It will be long before these desiderata are obtained, and it should be as long before tuberculin is used for other operative purposes.—*The Practitioner.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

DIE BEHANDLUNG DER FRAUENKRANKHEITEN. Von J. VEIT, M.D. 32mo; paper; 244 pages; illustrated. Verlag von S. Karger, Berlin.

OLD AGE DEFERRED. By ARNOLD LORAND, M.D. 32mo; cloth; 472 pages; price $2.50 net. F. A. Davis & Co., Publishers, Philadelphia, Pa.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week of April 1, 1911.

	Cases	Deaths
Tuberculosis Pulmonalis	481	177
Diphtheria	308	38
Measles	853	20
Scarlet Fever	659	34
Smallpox	—	—
Varicella	213	—
Typhoid Fever	21	8
Whooping Cough	93	12
Cerebrospinal Meningitis	14	7
Malarial Fever	—	—
Totals	2,642	296

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 31, 1911.

PLACE.	DATE	CASES.	DEATHS.
CHOLERA			
India: Calcutta	Jan. 29-Feb. 4		60
Madras	Feb. 12-18	7	2
Rangoon	Feb. 5-11	2	2

PURPURA.

By J. S. THACHER, M.D.,

NEW YORK.

HEMORRHAGIC disease, or the group of conditions manifesting an abnormal tendency to hemorrhage, either free or into the tissues, comprises a large and but loosely related collection of morbid states. We must, therefore, attempt to classify them, to find some natural grouping of these various conditions, and then to dismiss some of the simpler groups and some of those which are but minor features secondary to other well recognized conditions. We shall then be in a better position to study the more interesting and puzzling remainder.

A.—First, there are those due to mechanical conditions, as in heart disease; portal obstruction; conditions of muscular strain, as in epilepsy, paroxysms of coughing and parturition; embolism and thrombosis, and ulcerative conditions. These need not delay us at all.

B.—There are in the next place conditions of distinct disease of the vascular walls, as arteriosclerosis.

C.—Again, conditions of general malnutrition and intoxication, as in old age, poverty, scurvy, pernicious anemia, leukemia, pregnancy, diseases of the liver, chronic alcoholism, various chronic diseases.

Poisoning with iodine, mercury, antipyrin, phenacetin, chloral, copaiba, quinine, belladonna, arsenic, turpentine, ergot, salicylic acid, or snake venom.

D.—Also infections, especially smallpox, typhus, cerebrospinal meningitis, ulcerative endocarditis, other septicemias, scarlet fever, measles; and, less prominently, typhoid and paratyphoid fevers, gonorrhea, vaccination, pneumonia, and sore throats and mouth infections.

All these we may dismiss with but a few words, first, to recall that mild infections occasionally present an abundant petechial eruption.

I have recently had two cases with such eruptions, fine, bright, fairly profuse, following sore throat, and followed by speedy and complete cure without much assistance. In each case streptococci were abundant in the throat and in one a pure culture of streptococci was obtained from the blood. The treatment was simply local, of the throat. In the case in which we obtained streptococci from the blood, vaccines were prepared, but before they were ready the patient was improving and they were not used.

In another patient an unusual mouth infection was followed by a profuse eruption partly hemorrhagic. The case was one of whoopingcough in a child and moderate doses of antipyrin had been taken. The mouth infection in this instance took the form of an abundant, furry, white pseudomembrane and spread over nearly the whole mucosa of the mouth and fauces. The elements of this growth seemed bacillary, but the mass mycelial. Its appearance was shortly followed by an abundant eruption over various parts of the body, of hemorrhagic macules, and papules, with some bullæ. Recovery was prompt and the child has been since, as she had been before, perfectly healthy. It was not proved, but it seemed probable, that this hemorrhagic eruption of unusual form was due to a toxemia arising from the peculiar mouth infection. On the other hand, a petechial eruption is sometimes the first distinct warning that a patient may be in a very serious condition. It may be the clue leading to the discovery of a virulent septicemia or may indicate the serious type of an endocarditis.

Two minor groups of cases we will also dismiss, because they are infrequent and we know little

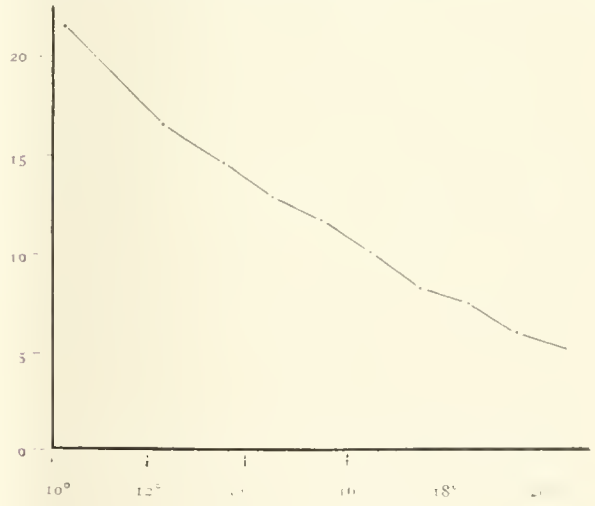

FIG. 1.—Times in which the same blood coagulates with different temperatures. The figures in the vertical column denote the coagulation time in minutes; the temperatures in the horizontal line are of the centigrate scale. (Plotted from Addis's figures—Brodie-Russell Oil Method of Addis.)

and understand less concerning them. These are:

E.—Nervous purpura, and

F.—Hematidrosis.

Purpuric eruptions have been reported as following fright in nervous individuals, as occurring in victims of hemiplegia and multiple sclerosis, and at the site of neuralgic pains. Hemorrhagic eruptions occurring at the menstrual periods and those reported as occurring periodically in men should, perhaps, also be classed as nervous purpura.

Having cleared away this miscellaneous assortment of hemorrhagic conditions, we find the field of our subject occupied by two groups which may be separated from one another with confidence that they are distinct conditions.

In one group the hemorrhagic tendency is strikingly hereditary, and as a rule pretty celearly congenital. The clinical picture, moreover, differs from

that of the other group in the great prominence of hemorrhages from the various surfaces and in the much less prominence of other symptoms. The blood, also, by certain tests, shows characteristic abnormalities. To this group should be given the exclusive right to the name hemophilia.

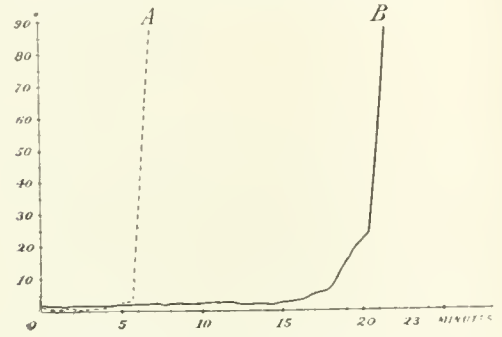

Fig. 2.—Coagulation curve of normal blood; A, at 40° C.; B, at 20° C. (Kottmann's Coagulovi.scosimeter.)

There are cases presenting a similar picture without the history of heredity. These may be variants of the same disease and courtesy should, perhaps, allow them the benefit of the doubt and the title, but for safety's sake arguments and conclusions regarding hemophilia should at present be based strictly on the cases which are clearly hereditary.

The hemorrhagic diseases of the new born are often spoken of as hemophilia, but they are thought to be of infectious origin and the use of the name hemophilia for them tends to confusion.

The remaining group is larger in the number of cases and more varied in its clinical picture. The clinical features which we find presented in various combinations by this group of cases are chiefly these: Hemorrhagic eruptions, from minute petechiæ to large ecchymoses; the eruptions of erythema multiforme, erythema nodosum, and urticaria; localized edema; symptoms of arthritis; crises of abdominal pain, often with vomiting or diarrhea, sometimes leading to a diagnosis of intestinal obstruction, and to operation; hemorrhages from the alimentary, the respiratory, or the urinary passages; frequently nephritis; rarely endocarditis and pericarditis. This group we may call idiopathic purpura.

It is interesting to note that, while hemorrhage is a frequent and striking symptom in this group of cases and prominent in our conception of this disease, the eruptions include not only hemorrhagic eruptions but the other eruptions just mentioned of erythematous, urticarial, and edematous types. Osler includes all of these under the term exudative erythema, and uses this as the name for the disease, presenting the eruption as the essential part of the picture, and the other features as complications.

These symptoms, occurring in this group which we call "idiopathic purpura," do not, of course, all of them occur in every case. Some cases are very mild and present but one or two of the symptoms. In some the joint symptoms are prominent, in others the visceral sympoms, in others the hemorrhages. Shall we, therefore, subdivide and further classify the idiopathic purpuras? This has been done for us in the following way: The cases in which the symptoms are very slight, with little beyond a petechial eruption, are put by themselves under the title purpura simplex. Those in which joint symptoms are prominent are grouped under the name of purpura rheumatica, or better, purpura arthritica; those with visceral symptoms prominent, under the name of purpura abdominalis or Hinoch's purpura, and those in which hemorrhage is a prominent feature, under purpura hemorrhagica. For convenience in studying and recording, it may be well to accept this classification, but it should only be done provisionally and with the admission that as yet no definite lines of cleavage appear between these groups. Each group, even little purpura simplex, may at times present any of the features which are made the bases of distinction for the other groups. Into a special group, called purpura fulminans, have been put those few cases which run a very brief and malignant course. They all, at least all typical cases, occur in children, are fatal, and rarely last longer than eighteen to forty-eight hours.

Can we now make any beginning toward an understanding of these conditions?

Anatomical studies have left us as much in the dark as ever in regard to the nature of the disease or diseases.

At autopsy lesions are often found, but they fail to throw light on the essential nature of the malady. Hemorrhages into the internal organs are frequently seen. The submucosa of the stomach and intestines is a favorite site for these hemorrhages. Necrotic foci have also been found in the walls of the stomach and intestines as well as in the skin. Nephritis is not uncommon, with marked glandular changes and much epithelial degeneration. Endocarditis and pericarditis are occasionally found, and the spleen is sometimes enlarged.

The majority of gross and microscopical investigations have failed to find any alteration in the blood-vessels. Even the fragility of the capillaries

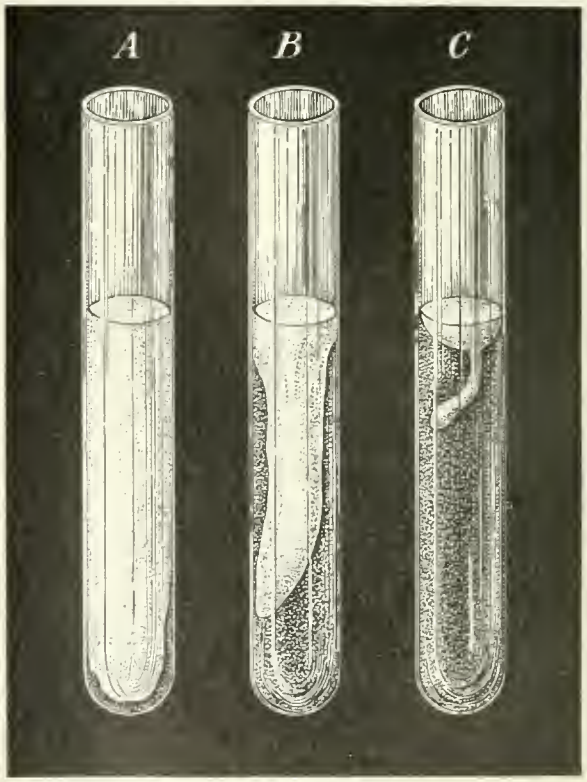

Fig. 3.—Reduction of clot with increasing amounts of platelets; A, oxalate serum + calcium chloride; B, the same + a few plates; C, the same + a larger number of plates.

seems not to be increased in hemophilics. This appears from careful observations made by Addis, who applied cups to hemophilic cases, using a definite negative pressure determined with a manometer, and comparing the results with those obtained on normal cases. He found that he caused

extravasation no more easily in the hemophilic cases than in the normal.

Suggestions of a bacterial or of a toxic causation for these conditions naturally occur to us. In the earlier days of imperfect methods there were numerous reports of bacterial findings in cases

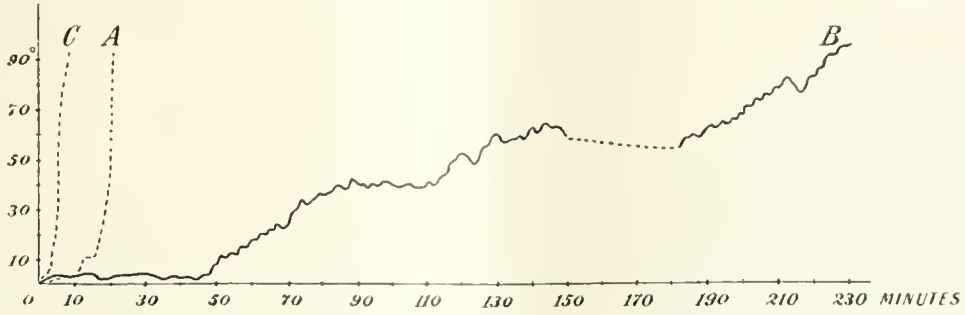

Fig. 4.—Curves of Coagulation Times: A, normal blood; B, hemophilic blood; C, hemophilic blood; + thrombokinase solution (1 c.c. blood + 0.5 c.c. filtrate of ground rabbit's liver).

presenting the picture of this disease, but of late years the findings of competent investigators, with more perfect methods, leave at least a large group of such cases without any evidence of infection. Such observations as Flexner's in regard to the hemorrhagin of snake-venom, and those of workers on anaphylaxis regarding the production of hemorrhages in that condition, suggest the possibility of a toxic origin of this disease, but experiments with the blood of such cases *in vitro* and injected into animals have failed to prove the presence of such a toxin.

The little light which has been shed on the nature of these troubles has come from studies connected with the coagulation of the blood.

The view which is now generally accepted regarding the process of blood coagulation is essentially that of Morawitz, and based upon his investigations. According to him, fibrin is formed by the union of fibrinogen and thrombin, also called fibrin ferment. Thrombin owes its existence to the combined presence of thrombokinase, calcium, and prothrombin or thrombogen. Morawitz also believes that there is normally in the circulating blood an antithrombin, which is essential in maintaining its fluidity while circulating. There is, moreover, evidence that the activity of the liver is necessary to the coagulability of the blood. Shutting off the abdominal circulation, injury to the liver, or its extirpation makes the blood non-coagulable. Under these circumstances there is lack of fibrinogen. Wolff claims to

Fig. 5.—Curves of coagulation time: A, hemophilic blood (1 c.c.) + calcium chloride (0.05 gm.); B, hemophilic blood (1 c.c.) + normal serum (0.05 c.c. from sister of the hemophilic.) (Kottmann's Coaguloviscosimeter.)

have also demonstrated that the liver forms substances which hinder fibrinolysis.

In the clinical study of the coagulation of the blood several new devices and improvements upon old methods have been used. Sir Almeroth Wright's method of determining the coagulation time by means of his capillary pipettes has been the basis of many interesting reports and suggestions from him, but too much reliance must not be placed on his findings. His method of determining the moment of coagulation is rather crude, and the method leaves largely out of account the great variations in the time of coagulation which may be produced by variations in the temperature. The accompanying chart (Fig. 1), made up from Addis's figures, shows how greatly the time of coagulation depends upon the surrounding temperature. A method which is now in quite general use is that which uses the coagulometer of Brodie and Russell, or a slightly modified one of Boggs, in which a stream of air keeps the drop of blood in motion until it coagulates, the cessation of motion being watched for through the microscope. This method has been made more accurate by Addis, who, instead of air, uses a constant stream of oil at a fixed temperature. Another means of determining the coagulation time which is probably still more accurate is the method of Doctor Kottmann, using his "coaguloviscosimeter." In this instrument a metal disc hangs in a small revolving cup containing the blood. The tension of the wire supporting this disc indicates the advance of coagulation by a pointer and a dial. The readings from this dial at regular intervals of time may be plotted into a curve, giving such results as are here shown. (Fig. 2.) Unless these very accurate methods are used, the simple old method of Milian, modified by Hinmann and Sladen, and again by Duke, is perhaps as satisfactory as any of the others in common use. That method consists in putting a drop of blood of a diameter of 5 mm. upon a glass slide, keeping it inverted over a glass of water at 40° C. and covered with a warm, damp cloth, and at frequent intervals tipping the slide into a vertical plane to see whether the blood has set or still sags. The normal coagulation time by this method is from 5 to 7 minutes.

The bleeding time may be approximately obtained by following a recent suggestion of Duke's and making a slight cut in the tissue of the skin, sopping up the drop of blood on a piece of blotting paper every half minute until the blood ceases to appear. The number of spots on the paper then indicates the duration of the bleeding. He has observed a number of cases in this way and claims to have obtained fairly constant or consistent results.

The counting of blood platelets is done in two ways, the direct and the indirect. By the direct method they are counted very much as the white cells are counted, using the ordinary pipette and a solution of cresyl blue with potassium cyanide. This solution lakes the red cells and stains the white cells and platelets. The normal number of platelets in 1 cu. mm. by this method is 225,000 to 400,000. By the indirect method the ratio between platelets

and red cells is determined in a stained smear, and the red cells of the same blood are counted in the usual way. A report on the direct method was read at the last meeting of the Association of American Physicians by Wright and Kinnicutt. Pratt believes that the indirect method is more accurate. It gives rather higher figures.

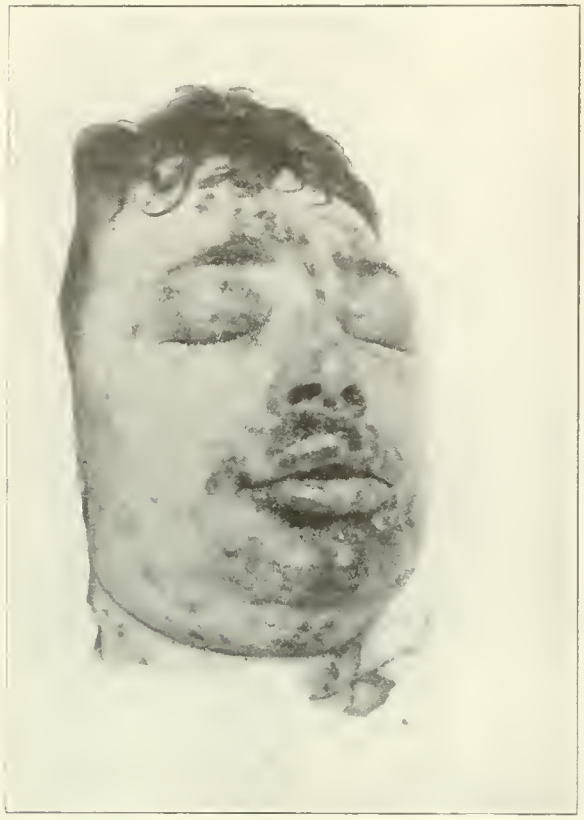

Fig. 6.

Retraction of the blood clot is studied by putting about 3 c.c. of the patient's blood into a small test tube and watching it. Normally, at the end of an hour it begins to be separated from the wall of the tube. At the end of 24 to 48 hours the contraction should be complete and the clot entirely surrounded by a layer of serum.

The study of cases of hemophilia and purpura by these methods has given results in which the various observers for the most part agree.

In true hereditary hemophilia the varied experience of investigators has shown that it is the rule to find an increase of the coagulation time, often to a very high degree. As Sahli says, "the single characteristic feature of hemophilia is the prolonged coagulation time." This he attributes to a diminished content or diminished availability of the thrombokinase in the blood corpuscles. One of the latest and most careful contributions to this phase of the subject is given by Addis, who has carefully tested twelve cases of typical hereditary hemophilia. Using the oil modification of Brodie and Russell's instrument, which gives with normal blood at a temperature of 20° C. a coagulation time of about 10 minutes, he found that in nine of these twelve cases the time was from 63 to 85 minutes. In one case, in which the symptoms were of moderate degree, 36 minutes, and in the remaining two cases, in which the symptoms were slight, 15 minutes. While this increase in the coagulation time is as a rule marked in these cases, it is, on the other hand, the general experience that they show no diminution in the number of platelets and no failure of the clot to contract.

In cases of jaundice with hemorrhage the coagulation time has also been found to be greatly increased.

In purpura, on the other hand, the coagulation time is as a rule normal. Pratt, using the Brodie and Russell instrument, found in thirty-four cases an average of 5½ minutes, which is well within the limit of his observations on normal cases. In the records of twelve cases in the Presbyterian Hospital I find the coagulation time recorded as not over 8 minutes in eight cases, and in the other four cases 9, 10¼, 10¾, and 11¼ minutes, respectively. Occasionally instances have been reported in which the coagulation time was delayed, but as a rule purpura, in this respect, differs markedly from hemophilia. The platelets, however, in cases of purpura with hemorrhage are generally much reduced in number and there is failure of the clot to retract. It is even thought by some that cases of purpura without eruption may be recognized by the diminution of platelets and the non-retraction of the clot. There is experimental evidence that the clot retraction depends upon the abundance of platelets. (See Fig. 3.)

Duke's observations on the bleeding time, made with his rather crude method in a few cases of purpura hemorrhagica with a low platelet count, found that though the coagulation time was normal the bleeding time was greatly prolonged, to 60 minutes or more, instead of the normal 1 to 3 minutes. In two cases of Henoch's purpura with a normal number of platelets he found the bleeding time normal, and in some cases of jaundice with greatly increased coagulation time the bleeding time was normal.

Fig. 7.

Further studies into the nature of purpura with

low platelet count are suggested by experiments showing that the number of platelets in the circulating blood may be experimentally reduced. They may be reduced by injections of albumose. Moreover, injections of serum from another species will produce a gathering of platelets into masses forming thrombi. Also, sera destructive to platelets may be produced by the usual methods of experimental immunity.

A great reduction in the number of platelets is also found in cases of lymphatic leukemia, in cases of pernicious anemia, and in cases of aplastic anemia, suggesting that, as in these diseases, so possibly also in purpura there may be trouble in the blood-making tissues. Marcel Labbé has written interestingly and with some clinical basis on the association in individuals of the characteristics of hemophilia, purpura, and pernicious anemia, and it may be that the conditions producing these different clinical pictures are so related that these can easily coexist.

As to the relation between rheumatic fever and the arthritis of purpura, these are probably two quite distinct conditions. In purpura rheumatica a previous history of typical rheumatic fever is the exception. The joint symptoms are not often so intense as in true rheumatism, and the fever is not so marked. Endocarditis is less common and the pain less yielding to salicylates. Moreover, a purpuric eruption rarely occurs in rheumatic fever and, on the other hand, joint symptoms occur in various diseases other than rheumatism, especially in such as are associated with extravasations of blood.

The treatment of these conditions is not satisfactory, although some interesting additions have been made in recent years to our means of overcoming some forms of hemorrhagic disease. The older remedies have been of little help. Arsenic has sometimes appeared useful, as has also turpentine. In an extreme case of purpura, for which I had tried various remedies without result, the administration of turpentine was promptly followed by rapid improvement and complete cure. The interesting studies of Wright, and the enthusiastic reports which he and his followers have given of the effects of lime salts in shortening the coagulation time and diminishing the tendency to hemorrhage, have been interesting and stimulating. Others, however, have used these salts in vain. Wright himself admits that the coagulation time may sometimes be increased by taking calcium, explaining this as due to too great an absorption of the salt. His results are confirmed by many, but have been criticized by others, partly because of their lack of confidence in his method of determining the coagulation time, partly because of experimental evidence that the calcium content of the blood does not affect the coagulation time, and partly because of clinical failure in its administration. (See Figs. 4 and 5.)

The use of gelatin by mouth is of doubtful efficacy, its use hypodermically is of some danger, and Boggs' experiments failed to show that gelatin reduced the coagulation time of the blood.

Weil, after showing that normal serum either from man or from animals, as well as pleuritic fluid, has a marked effect on the clotting of hemophilic blood, tried the use of normal sera clinically in a few cases of hemophilia and purpura, with fair results. Leary used normal rabbit serum, in doses of 15 c.c. intravenously, or 30 c.c. subcutaneously, in nine cases of jaundice with hemorrhage, three cases of hemorrhage of the newborn, one of hemophilia, and one of purpura, obtaining in general favorable results. The most striking success with the serum treatment of hemorrhagic conditions is that reported by Welch. He used normal human blood serum subcutaneously in nine cases of hemorrhage of the newborn. In every case the hemorrhages stopped promptly after the administration of serum. The one child who died lived forty nine days after the cessation of hemorrhage. Compared with the high mortality in such cases, these results are very striking. It must, however, be remembered that hemorrhage of the newborn is in all probability of a different nature from purpura and hemophilia.

Transfusion has also shown a striking efficacy not only in hemorrhage of the newborn, as in Lambert's case, but also in purpura. Duke reports a case of acute purpura hemorrhagica with a platelet count of 6,000 and 3,000, a bleeding time of 47 minutes, 90 minutes, and 50 minutes, but with normal coagulation time. Six hours after transfusion the platelet count was 123,000, the bleeding time 3 minutes, the coagulation time unchanged. After a few days the platelet count and bleeding time had gone back to near their previous figures, but after this, without further transfusion, the blood gradually resumed a normal condition and retained it.

In looking over the histories of cases of purpura which have come into the Presbyterian Hospital, in which eruptions, hemorrhagic, erythematous, urticarial, and edematous, hemorrhages from the mucous surfaces, pains in the joints and in the abdomen, and evidences of nephritis occurred in various combinations and various degrees, I find two cases of special interest.

The first, a young man of 25, well developed and well nourished, and after his recovering presenting a picture of sturdiness and general good health, was remarkable for the extent and the intensity of the superficial lesions. These were hemorrhagic, erythematous, urticarial, and edematous. The hemorrhagic spots varied from small petechiæ to large hemorrhagic areas a couple of inches in diameter, some bright red, some dark, almost as if necrotic. They were found upon the mucosa of the mouth and pharynx as well as upon the skin. Some of the erythematous spots presented red circles with white centers, some of them red areas with darker red centers, some more than two zones of different shades. Some were crescentic. Some of the spots were sharply raised and firm; that is, distinctly urticarial. Edematous areas accompanied the other changes in the skin, appeared over painful joints, and again were independent of both. At one time the scrotum became edematous and a circumscribed area of edema appeared on one side of the penis. These different appearances came and went with utter irregularity. More than once his eyes were completely closed by the swelling of the lids, and at one time his nose looked as if it would slough off. The accompanying photographs show his appearance at different times. (Figs. 6 and 7.) Different joints were at times quite painful, and he had some severe attacks of abdominal pain. The heart showed signs of mitral and aortic regurgitation. He gave a history of previous attacks of arthritis. The urine at first showed marked signs of nephritis, but afterwards became normal. The hemoglobin came down from 90 per cent. to 50 per cent., but afterwards went back to 90 per cent. again. The blood platelets were twice counted, giving 336,000 and 276,000. The coagulation time was taken twice and found to be 6 minutes and 7 minutes.

He was treated with salicylates, which sometimes seemed to relieve his pain; with chloride of iron and ergot, without apparent effect, and finally with oil of turpentine, which appeared to inaugurate his convalescence.

He felt and seemed to be perfectly well when he left the hospital.

Another striking case, on Dr. Eliot's service, had had previous attacks of arthritis following gingivitis, and followed by the appearance of purpuric spots on the hands and fingers. She had also had some hemorrhagic eruption on the body. Upon admission she complained of pain in the left flank and left hypochondrium, which she said she had had for three months. She had vomited during the day, first undigested food, later some yellowish material, and in the hospital a good deal of dark, thick material resembling prune pudding. She was markedly anemic, the gums swollen and angry, with purulent material exuding between the teeth, tender, and bleeding, and at one point ulcerated. The abdomen symmetrical, slightly distended, rigid all over, and markedly tender. Over the arms, chest, back, and legs a profuse hemorrhagic eruption, the spots varying in size from a pinhead to small blotches. The pulse was small and very rapid. From time to time the patient writhed in pain. After she had been in the ward about two hours she became suddenly worse, going into collapse, the abdomen became very hard. Laparotomy was performed by Dr. Eliot; the peritoneal cavity was found to be filled with gas and a large amount of dirty black fluid, with dark sediment containing stomach contents. Of the anterior wall of the stomach a portion was lacking, of the size of the palm of the hand, and extending from the greater curvature almost to the lesser, with a sharp border. Through this opening the mucous membrane of the posterior wall was visible. She died in a few hours. The autopsy found a large part of the anterior wall of the stomach lacking, as at the operation. Most of the remaining stomach wall was black, with the mucosa raised and thickened, excepting an area near the fundus, where the stomach wall appeared normal. Microscopical examination of the stomach wall showed in places the entire thickness necrotic, in other places the mucosa necrotic over a normal muscularis, the outlines of the necrotic areas being sharply defined.

AN UNUSUAL CASE OF FRACTURE OF THE BODIES OF THE FOURTH, FIFTH, AND SIXTH CERVICAL VERTEBRÆ, WITH INJURY OF THE SPINAL CORD.*

By W. H. SWAN, M.D.,
COLORADO SPRINGS, COLO.,
CHARLES A. POWERS, M.D., AND
HOWELL T. PERSHING, M.D.
DENVER, COLO.

HISTORY (BY DR. SWAN).

The subject of this report was a man, aged 70, who had always been remarkably active physically and mentally. He had been for years harassed by a gouty eczema and had been treated for arteriosclerosis some years before. About seven months prior to the injury to be described, after a hard day's ride and tramp in the mountains, he had acute dilatation of the heart, from which he suffered up to the time of his accident, though he persisted in long rides and unwarranted exercise. About noon, October 27, 1906, while riding, his horse stumbled. He was thrown, evidently striking on his forehead. There was immediate and complete motor and sensory paralysis below the neck without loss of consciousness. There was involuntary evacuation of bladder and bowel at the time of the accident and again after being put to bed. A passing automobile carried him to his home, a mile distant, he giving directions as to how he should be moved. He was seen by the writer about an hour after the accident, when the following conditions were noted:

Patient pale, pupils widely dilated, anxious expression, extremities cold, entirely conscious, complaining of tingling of all extremities, pulse imperceptible at the wrists, complete loss of voluntary

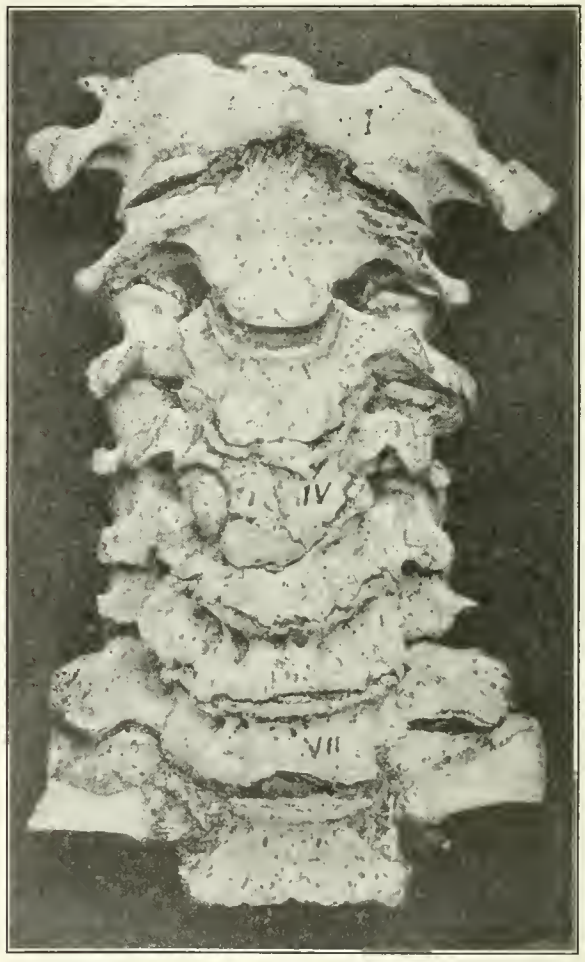

Fig. 1.—Cervical and first dorsal vertebræ; anterior view

motion, except of the head, which motion was painful. All sensation abolished below the level of the third rib in front. There was a bruised excoriated area over the bridge of the nose and forehead. Urine and feces in the removed clothing and in bed. Breathing not embarrassed, regular, but superficial. The pulse was not felt at the wrists till after four hours' free stimulation.

The patient was seen in consultation by Dr. C. F. Gardiner of Colorado Springs and, later, by Drs. Howell T. Pershing and Charles A. Powers of Denver. The notes as to the neurological and surgical conditions and changes will be given by the latter two gentlemen.

By the use of moderate doses of morphine the patient passed a fairly comfortable night, requiring

*Read before the American Neurological Association, Washington, May, 1910.

catheterization; priapism was present. No difficulty in swallowing.

The second day, pulse 56 to 72, good character. During the latter part of the day there was marked abdominal distention which embarrassed breathing considerably, but was relieved after calomel and enemata. The third day itching, which had been absent since the accident, became very marked on the neck and chest and corresponded to a sharply defined bright red zone, the lower limit of which was a line across the chest at the second interspace. This persisted for two or three weeks, after which there was neither itching nor redness.

During four or five weeks following the injury he was catheterized three times daily and had no irritability of the bladder. From that time up to the time of his death he was catheterized from four to ten times in twenty-four hours, the frequency varying without apparent physical cause. Only once was there a considerable infection of the bladder which cleared up after a few days. Many times the urine became somewhat cloudy when the use of urotropin was tentatively stopped, but at once became clear when it was again administered. With these exceptions he was given urotropin continuously during the twenty-eight months of his illness in daily doses of ten to thirty grains. There were apparently no harmful effects from it unless it had to do with the constantly low solids in his urine during the last twenty-four months of his life.

He never regained control of his bladder, though after three months he could reinforce the flow and a few times voluntarily passed one or two ounces. The strictest aseptic precautions were constantly used in catheterization, including sterile gowns, rubber gloves, and a sterile dressing about the penis between catheterizations.

During the first four or five months of his illness he ate freely and the urine was very abundant, with high solid content, containing many hyaline and coarse granular casts. From that time on he ate very little, the solid content was constantly low (from 8 to 20 grams in twenty-four hours) and rarely showed casts.

There was often marked tympanites and digestive disturbance, but, for the most part, the bowels were easily moved daily by laxatives and enemata. Occasionally there were loose involuntary movements.

There were a number of periods of great weakness and mental hebetude, which were relieved by free elimination by the bowels and aided, apparently, by the use of diuretin. There seemed, at times, to be an element of mental fatigue in this depression. Sleep was always difficult, requiring constant use of hypnotics.

At the end of nine weeks the patient was up daily, taken out in a wheel chair, and very soon was lifted into his automobile and taking long rides. During the following year he often drove for five or six hours a day, with no apparent fatigue, was taken to a number of social functions in his own and adjoining towns, and took keen, active interest in all affairs of life. Mentally he was extremely active, at times giving close application to business affairs for six or seven hours a day. He frequently remarked that he had never been able to turn off so much work or to give so much time to the enjoyment of his friends.

He became able to write short notes (writing by whole arm movement); could, with effort, feed himself by means of a spoon or by taking food in his right hand; was often taken to the dining table, and about his house and grounds in his wheel chair. He could move his legs to a considerable degree (the right leg and arm much more than the left) but could never stand or sit alone, nor was he ever able to materially change his position in bed without help.

The heart at times showed a systolic murmur of the apex, but from the time of his injury was entirely competent. Probably the enforced physical rest gave the heart an opportunity to acquire compensation and, in this way, the writer suspects that the injury prolonged the patient's life.

Once there was redness with slight induration of the skin over the sacrum. This occurred after a few days' refusal to lie on a water bed and promptly cleared up when he returned to it. Much credit is

Fig. 2.—Cervical and first dorsal vertebræ, lateral view.

due Dr. H. C. Watt, who acted as resident physician, and to his most competent and faithful nurses in averting serious bladder infection and bed sores during this long period.

At the end of eighteen months he had become more sleepless and depressed. He then went to England, making the trip very comfortably. During his six months' stay there he had an attack of bronchitis and lost ground in all ways, coming home in November, 1908, considerably weaker physically and less active mentally than when he left.

During the winter he drove in his automobile almost daily, up to two days before his death, when he became uremic, and died March 13, 1909, twenty-eight and one-half months after his injury.

The points of general interest in the case seem to be: (1) The marked mental activity and endurance

of the patient; (2) prolonged excessively low solid content in the urine; (3) prolonged use of urotropin without apparent harm; (4) relief from long standing eczema; (5) the acquiring of compensation in a weak heart by enforced rest; (6) avoidance of bedsores and cystitis.

SURGICAL CONSIDERATIONS (BY DR. POWERS*).

On the afternoon of Saturday, October 27, 1906, I was summoned with my friend, Dr. H. T. Pershing, to see General P., a gentleman of 70 years, at his country place near Colorado Springs. We arrived at the house at half past seven o'clock, finding Dr. W. H. Swan and Dr. C. F. Gardiner in attendance. According to the history the patient had been thrown over the head of a stumbling horse while riding, probably striking upon his head, at twelve o'clock the same afternoon. Upon the receipt of the injury he found himself unable to move. He had been taken to his home, a distance of a mile. He had not suffered much pain; he had not vomited. The temperature had been normal, the pulse had been practically imperceptible but was then normal.

Dr. Swan, Dr. Gardiner, Dr. Pershing, and I proceeded to a methodical examination.† The arms were in semi-abduction, the forearms were flexed. The lower extremities were motionless, there was anesthesia to about the third rib. The patient had not urinated (involuntary evacuation at time of accident) and was unable to urinate. Eight ounces of normal urine were withdrawn under rigid asepsis.

There was a slight abrasion over the left forehead. The patient was able to move the head and neck in any direction; motions of the head and neck were practically normal. Careful palpation of the spinous processes of the cervical vertebræ seemed to show a slight irregularity at about the fifth spinous process. A gloved finger introduced into the pharynx discovered no irregularity or tenderness. There was a slightly tender spot at the back of the neck at about the fifth and sixth vertebræ. The mind of the patient was entirely clear; he expressed himself as being comfortable.

A provisional diagnosis of fractured cervical vertebræ in the neighborhood of the fifth and sixth, with injury to the spinal cord, was made, and general supportive treatment ordered. All bony prominences were most carefully protected, rigidly aseptic catherization of the bladder was ordered every eight hours.

On the following day Drs. Mayhew and Childs took *x*-ray pictures. These showed an irregularity of the third and fourth spinous processes, with practically no irregularity of the bodies or arches of the vertebræ. The question of operative interference was thoroughly and carefully discussed. It was definitely and unanimously decided in the negative for the following reasons: The patient was advanced in years and it seemed exceedingly improbable that a remedial lesion would be found.

My esteemed colleagues will present to you the exact neurological diagnosis, the electrical responses, etc. My own surgical conviction was clear that the patient suffered from a broken spine with injury to the spinal cord (hematomyelia) and that he should not be submitted to any form of operation. In this, as I have said, I had the unanimous support of my confrères. Fixation of the neck was also decided in the negative.

The surgical management instituted was very simple. A few hours after the accident the patient was placed on a suitable water bed. A resident physician, Dr. H. C. Watt, whose efficient zeal was untiring, was installed in the house. He attended to the aseptic catheterization of the urinary bladder and he personally inspected all portions of the patient's skin daily. A daily journal was kept in which the condition of the skin was certified, a complete examination of the urine recorded, and the general condition of the patient noted. This rigid régime was kept up until the death of the patient, some twenty-eight and one-half months after the accident. Its efficiency is attested by the fact that at no time during the life of the patient was the skin broken or the bladder definitely infected.

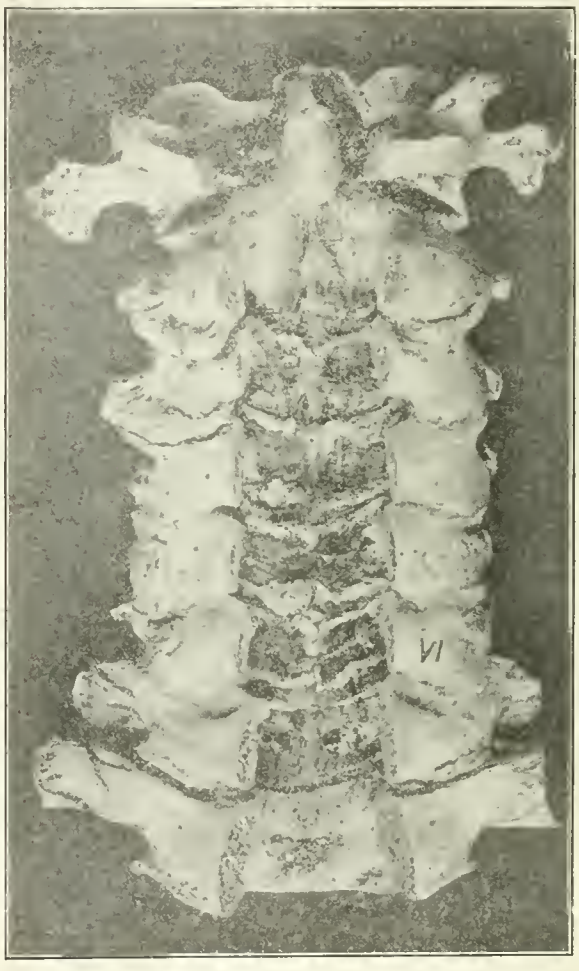

FIG. 3.—Posterior view, arches removed.

Dr. Swan has laid before you the general course of the patient. Dr. Pershing will give you the interesting neurological details. At the request of the patient's family a complete autopsy was made by Dr. J. A. Wilder directly after death. I am permitted to hand to you this very interesting anatomical specimen of the cervical spine. You will observe that the bodies of the fourth, fifth, and sixth vertebræ are moderately crushed together without buckling of the spine or encroachment on its canal. I believe a study of the specimen to show that operative inter-

*The author thanks the officers and members of the American Neurological Association for their kind invitation to take part in this discussion.

†We jointly remained in constant attendance for something over two weeks. Dr. Swan continued as attending physician while Dr. Pershing, Dr. Gardiner, and I saw the patient frequently in consultation. Drs. S. Weir Mitchell and Dr. M. Allen Starr came to Colorado in consultation and rendered valuable aid.

ference, while very dangerous to a man of the years of our patient, would have been without avail. (Figs. 1, 2, and 3.)

In concluding this very brief summary I beg to say that I have never before known a patient with such an injury to be accorded the rigid hourly care which this man received. I have never before known a patient to go through twenty-eight months of similar spinal paralysis without a broken skin or badly infected bladder.

You will, perhaps, allow me a brief word on the matter of operative interference in spinal injuries. This interesting topic has recently been made the subject of exhaustive study* by De Quervain (of La Chaux de Fonds). He made a formal report on it at the 1908 meeting of the Société Internationale de Chirurgie at Brussels. De Quervain sent a comprehensive set of questions to all the members of the International Surgical Society and tabulated the answers† which he received from sixty-seven surgeons in different parts of the world. These sixty-seven surgeons reported 218 operative cases. The German, Austrian, English, and Swiss surgeons manifest a marked hesitancy in restoring to surgical interference, many surgeons with abundant material at their command express themselves as having never found operative indications. On the other hand, the French and American surgeons furnish a very considerable number of operative reports.

This complete paper of De Quervain, together with the discussion of it, is worthy of careful study in the original.‡ I may lay before you the author's conclusions, which are as follows:

1. We do not know any clinical syndrome that can be ascribed to spinal commotion, viz., purely functional troubles without any anatomical lesion.

2. Our present knowledge as regards diagnosis enables us in most cases to make with practically complete certainty a distinction between a partial and a complete lesion. Some cases of partial lesion nevertheless present themselves during the first hours and even during the first days, with all of the symptoms of a total lesion. The Bastian-Bruns law concerning the definitive loss of the tendon reflexes in case of total traumatic lesion of the spinal cord in man finds confirmation in practically all cases, meaning by this that the presence of these reflexes makes the absence of a total lesion practically certain. On the other hand, the loss of these reflexes cannot be considered absolute proof of an actual total lesion, unless such loss be persistent. In many cases of partial lesion temporary loss of tendinous reflexes is observed. In some cases this loss persists more than eight days.

4. The nature of the nervous troubles does not enable us to make a distinction between medullary compression and contusion. The conclusions arrived at as regards the nature of the vertebral lesion give nothing more than probabilities. (Radiography? C. A. P.) The differential diagnosis between extra medullary hemorrhage and hematomyelia is easier but by no means always certain.

5. According to experiments done on dogs and rabbits (adult) neither the fibers nor the nerve cells are capable of regeneration, for one has only been able to observe some starting formation of nerve fibers in the scar or along the uninjured dura, both devoid of any importance from a functional point of view.

6. The traumas of the spine are in no way comparable, as regards operative indications, to the traumas of the skull.

7. Neither extradural hemorrhage nor intradural hematoma provide, as a general rule, operative indication, unless compression of the mid part of the cervical cord by a hematoma without concomitant contusion of the cord (a diagnosis difficult to make) imperils the life of the patient through progressive respiratory trouble. Late operation is indicated by incomplete resorption of the hematoma.

8. Operation must be proscribed in cases where the symptoms speak in favor of hematomyelia.

9. Early operation is indicated: (*a*) When the nervous troubles can be attributed, after clinical examination, to the fracture of an arc; (*b*) when, in a lesion by firearm, the radiographic examination shows the presence of a projectile in the vertebral canal.

10. An early intervention may be useful, without presenting, however, much chance of success: (*a*) When, in a dislocated fracture, attempt at bloodless reduction has failed and the patient presents the symptoms of a partial lesion (favorable results in cases of compression between body and arc, but quite useless in cases of contusion); (*b*) when, in the lesion by firearm, the projectile is not lodged in the medullary canal (good results in cases of compression by a bone splinter, bad in case of contusion or partial section of the medulla).

11. Late intervention is indicated: (*a*) If, in the prementioned cases (9 and 10) early intervention has not taken place and the nerve symptoms have not improved spontaneously; (*b*) if an ulterior aggravation of the symptoms should happen in a case of partial lesion (compression by a callus, especially in cases of fracture by compression).

12. Operation has hitherto been proscribed in all cases of total lesion early established. This rule will be greatly modified if the success of the medullary suture is confirmed. It will no longer be available only for total sections of the cervical regions. Here, indeed, restitution would come too late to avoid a fatal issue.

In all total lesions situated low, per contra, suture may be tried, on condition that the medulla be not destroyed to too large an extent. Trials should therefore be made especially in all cases of lesions by edged weapons and by firearms. Cases where the contusions are well limited will nevertheless not be absolutely excluded (case of Briggs).

13. The late systematic examination of subjects having undergone laminectomy should inform us as to the degree of inocuousness of this intervention with regard to the appearance of subsequent trouble attributable to the operation. This examination must take into account the operative process, so as to permit a study of comparative value.

14. The study of collective statistics (218 cases) bearing on the good and bad cases provides us with the following results:

Cured	13 8 per. cent.,	of which 10 per cent. visibly influenced by surgical intervention.
Improved	22 per cent.,	of which 16 per cent. visibly improved by surgical intervention.
Remained without change	37 2 per cent.	
Unfavorably influenced	1 8 per cent.	
Died soon after operation	25 2 per cent.	

*It is not necessary to say that the literature of this subject is both extensive and accessible. For lack of space I quote only from De Quervain, whose conclusions seem to me to be logical.

†It is but proper that I should say that my own results (five cases) there published are quite as discouraging as any reported by other surgeons.

‡IIme Congrès de la Société Int. de Chirurgie Vol. II.

NEUROLOGICAL CONSIDERATIONS (BY DR. PERSHING).

When I first saw the patient, about eight hours after the accident, he had reacted from the severe shock. There was some pain in the lower cervical spine and inability to find and maintain a comfortable position for the head. The arms abducted; elbows, wrists, and fingers flexed. The patient could powerfully increase abduction at the shoulders and flexion of the elbows and very slightly flex the right thumb. All other motions of the upper limbs were lost. The lower limbs were completely paralyzed.

Knee jerks and heel jerks were about normal. The only plantar response was a slight and exceedingly sluggish extension of the great toe on each side. The cremasteric response was not elicited then nor afterward. There was moderate priapism. Sensibility to touch and pain was completely lost up to the third ribs in front; it was not tested on the back.

The morning after the accident the patient's general condition was surprisingly good. On being asked if he could move his head he alarmed all present by raising it from the pillow and moving it vigorously in all directions. He could supinate and very slightly pronate the right arm and the motion of the right thumb had increased. There was a very little sensory loss in the upper limbs, mostly on the ulnar side, but not at all defined in extent.

Within the next few days there was a gradual return of power to extend the right hip, knee, and ankle and to flex and slightly extend the right wrist and thumb with increased power of pronation and supination. This return of power on the right side was followed later by a similar but much smaller gain on the left side. Sensibility, on the other hand, returned earlier on the left side, touch improving first, then pain, and last temperature sense, the right side always being decidedly more anesthetic than the left.

The upper limit of sensory loss remained sharply defined by a line over the third ribs in front and the spines of the scapulæ behind. Faradic tests, first made nine days after the injury and repeated from time to time, never showed a complete loss of irritability in any muscle but the clavicular portion of the left pectoralis major and the left infraspinatus showed less faradic irritability than the corresponding parts on the right side.

No muscular atrophy was noted except that some wasting of the first interosseous muscle in each hand, worse in the right, was apparent after about three months. What was left of these muscles reacted to the faradic current. There was never any marked spasticity or exaggeration of tendon reflexes in the lower limbs, except a slight left ankle clonus, elicited at only a few examinations.

The first neurological question was: What is the location of the lesion in the cord? The sensory loss did not definitely answer this question, because the sharp lines of demarcation were the axillary line separting the fourth cervical from the second dorsal sensory area, indicating only that the lesion was in the lower part of the cervical enlargement, while on the arms the segmental sensory areas could not be distinguished.

The motor loss, however, gave a more definite answer. Complete paralysis of the triceps muscles and the adductors of the shoulder with retention of full power in biceps and deltoids could be explained only by a lesion as high as the seventh segment, probably not seriously involving the sixth, certainly not the fifth. It was obvious that the lesion was bilateral but greater on the left side.

The faradic reactions were valuable rather as an assurance that no great damage could have been inflicted on the anterior horns or anterior roots anywhere, than as an aid to localization, although the slight loss of irritability in the left pectoralis major and infraspinatus might have referred to damage of the sixth segment or root fibers.

As to the nature of the lesion, it being regarded as mainly in the seventh segment and this being enclosed by the sixth vertebra, a fracture dislocation of the fifth vertebræ on the sixth, with both contusion and hemorrhage, seemed probable. The assumption of fracture was hard to reconcile with the free and extensive motion of the head already recorded, but this difficulty was regarded as more than offset by the other symptoms and the uniformity with which fractures are found at autopsies in such cases. As to the proportionate amount of damage done by contusion and hemorrhage, respectively, one could only conjecture, but the relative escape of the gray matter led us to hope that hemorrhage around the cord might be a large factor and that its absorption would lead to great improvement. Against this Dr. Mitchell urged the fact that the paralysis and numbness were practically instantaneous.

As to whether a displacement of bone was causing continuous pressure, thus making operative interference advisable, the neurological signs could not answer decidedly, but we could see no evidence of such continuous pressure and the early improvement was against it.

The vivid contrast between the eruption of eczema which remained above the level of the lesion and the clear white of the anesthetic skin, separated as they were by a sharp line, was very impressive. Evidently, in this case of eczema, at least, some influence from the brain was an essential factor in keeping up the eruption.

It also seemed to me that the brain itself gained something by having part of the sensory impulses from the body stopped at the site of the lesion. While always complaining more or less of pain or vague distress, sometimes having short spells of depression, and never showing any pathological exaltation, the patient bore his terrible disability with remarkable cheerfulness. He took the greatest interest in his family and social relations, enjoyed simple recreations, and was active in philanthropic work, sometimes on a very large scale and again in many minor ways. He was clearly conscious of a change in his coenesthesis and expressed surprise at finding himself happier than before the injury. This condition lasted for the most part until he left for England in June, 1908, but on his return in November he was somewhat depressed and remained so until his death.

Autopsy.—The aorta shows a few small atheromatous patches. Wall of the left ventricle thinner and its cavity dilated. Cardiac valves competent. Lungs, stomach, intestine, liver, and spleen normal. Kidneys on microscopical examination show subacute, diffuse inflammation. Bladder wall thickened; mucosa shows areas of congestion but there is neither mucus nor pus.

The cervical and first thoracic vertebræ with section of cord enclosed were removed *en masse*. The bodies of the fourth, fifth, and sixth cervical vertebræ have been fractured by a crushing force, the

fragments having united in nearly normal position, while the spinous processes, laminæ and articular processes remained uninjured. From the junction of the lower edge of the body of the fifth and the upper edge of the body of the sixth a small exostosis projects about two millimeters into the spinal canal. It extends from the median line to the left and leaves a linear impression across the ventral surface of the upper part of the seventh cervical segment of the cord. There is not a sign of counter pressure from the laminæ on the dorsal surface and the peridural space is otherwise normal. Incision of the cord at this mark reveals a lesion bilateral, although mainly on the left side, not noticeably softened but discolored as by hemorrhage. Details of the histological examination of the cord, unfortunately, cannot be given, but the usual ascending and descending degeerations are well marked on both sides.

REPORT OF FOUR CASES OF URETERAL CALCULUS.

By H. D. FURNISS, M.D.,

NEW YORK,

ADJUNCT PROFESSOR OF GYNECOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ASSISTANT SURGEON, CITY HOSPITAL; ASSISTANT ATTENDING GYNECOLOGIST, NEW YORK POST-GRADUATE HOSPITAL.

The following four cases give clinical histories very different from one another and for this reason are quite instructive. They indicate that ureteral calculi may exist with few, if any, of the classical textbook symptoms.

Case I.—Mrs. H. was seen through the courtesy of Dr. Edward Quintard, in whose service she was admitted. She is fifty-seven years old and the mother of three children, the oldest of whom is thirty-three and the youngest twenty-three. Labors

Fig. 1.—Case 2. Two large and one small stones in right ureter, the lowest being three and a half inches from the vesical orifice of the ureter, as measured by a ureteral catheter.

and puerperia were normal and she had an uneventful menopause at the age of forty-eight. Her previous history was negative. One year ago the patient for the first time experienced colicky pain in the left renal region, which did not radiate to the front, upward, or downward, nor was it referred to the opposite side. This pain lasted twelve hours, and during the attack the patient had nausea and vomited ten or twelve times. There was no frequency of urination during this attack, but a month

Fig. 2.—Case 3. Two stones in left ureter. The tip of the bougie is 4 inches from the vesical orifice of the ureter.

later the patient began to be troubled with frequent micturition and this has existed to the present time. During this period she has had three other attacks, but none as severe as the first. The patient favors the left side in walking and finds that this makes her more comfortable. The urine has a specific gravity of 1018, is clear, and contains neither albumin, sugar, casts, nor crystals; it contains a few leucocytes and a few red blood cells. The physical examination of the abdomen reveals nothing abnormal, and in the pelvic examination the only abnormality found, except slight perineal and cervical lacerations, is a small elongated mass felt in the region of the left ureter to the left and slightly behind the cervix. On cystoscopic examination the bladder appears normal and the two ureteric orifices are alike. A catheter inserted into the left orifice meets an obstruction three-quarters of an inch up that is passed with considerable difficulty. A wax-tipped catheter was passed and all the wax scraped off. A radiograph shows a shadow in the ureteric region at just the point of obstruction. While urine was seen escaping from the left ureter, it was not collected, nor was a functional test of the two kidneys made. While these procedures will be carried out, they are not of much importance in this instance, as the stone can be removed per vaginam, an operation in itself that will not further damage the kidney, even if this is already crippled. So far the patient has objected to any cutting operation, and for this reason we have resorted to the dilatation of the ureter through a Kelly speculum. The ureter has been stretched so that it will take a No. 20 French sound, which is larger than the stone, but the latter has failed to come through. This is to be explained as due to the postoperative swelling of the ureter.

Case II.—Mrs. E. R., aged fifty-three years, married at twenty, widow since forty-eight. Nine chil-

dren, oldest thirty-two, youngest ten. All labors and puerperia normal. No miscarriages nor abortions. Previous history negative. In good health until five years ago, when she began to have attacks similar to those for which she consulted the writer. In this time these attacks have occurred at intervals of eight to ten weeks, but of late every three weeks and with increasing severity. The attack begins with lassitude for a few hours, followed by a sensation of lameness in the outer side of the right thigh. After the existence of this for a few hours there is pain in the right renal region; this pain soon radiates to the front and downward along the course of the ureter to the bladder. Then occurs frequency of urination; the patient passes urine every few minutes and the act does not relieve her of the desire. During an attack the urine is clear. After about twelve hours the patient is relieved of the pain, but is prostrated for a week. The day following an attack the urine is quite turbid. The patient has never been seen in an attack and we have had no chance of examining the urine that is then passed. Occasionally she has been jaundiced and has vomited. An attempt was made to catheterize the ureters and distend the kidney pelvis with boracic acid solution to the point when colic would be produced to determine if the produced pain would be like that complained of (Kelly). An obstruction in the ureter was met three and one-half inches from the vesical orifice. A radiograph showed shadows of two large and one small stone at this point. Both ureters were catheterized and indigo carmine was injected into the buttocks. Blue colored urine flowed from the left ureter in twelve minutes. No flow of urine nor discoloration came from the right ureter. On several occasions the ureters have been catheterized and the flow of urine only from the left ureter observed; this was certain evidence of destruction of the right kidney. Under ether anesthesia an incision was made at the outer border of the right rectus through the transversalis fascia, the lower end of the incision being one and a half inches above the level of the symphysis and the upper just short of the umbilicus. The peritoneum was stripped from the pelvic wall to a point below the ureter, the ureter going with the peritoneal reflection. The stones were felt and the ureter above them held with a sponge forceps. A small longitudinal incision was made into the ureter and the stones were removed by pressing them out (they were quite adherent to the ureter), and the opening in the wall was closed with a few fine catgut stitches. A stab wound was made from a point over the iliac crest to the wound in the ureter and a cigarette drain inserted. The wound was closed in layers with catgut. The drain was removed at the end of forty-eight hours and the wound healed by primary union; the patient got up from bed on the ninth day and returned home on the thirteenth day. This patient was seen October 24 and reported that she had had no symptoms of her former trouble.

Case III.—The wife of a Canadian physician was seen June 12, 1910. She is a woman forty-seven years old, who passed the menopause at forty-two uneventfully. She has had seven children. Her first labor was instrumental, she had puerperal fever, phlebitis in both legs, and was quite ill for five months. For three years she had attacks of pain in the right kidney region, associated with temperature, and constant pyuria. After three years, during which she had several attacks, she had a severe one which terminated after the discharge of a large amount of pus from the bladder. This was the last time she had any pain in the right side. Two months later she began to have attacks of pain in the left kidney region, associated with nausea and temperature. During an attack the urine would be clear, but between attacks there was pus constantly. In the past year there have been several of these and the severity is more marked with each succeeding attack. She has no frequency of urination except at night. The pelvic examination is negative. The bladder and both ureteric orifices appear normal. No. 5 catheters are passed easily to the pelvis of the kidney on either side. The urine from the right kidney is clear, that from the left is turbid from the presence of pus. Examination of the urine for tubercle bacilli is negative. The possibility of ureteric stone was suggested to the husband and radiographs of the entire urinary tract were ordered. The first

Fig. 3.—Case 4. Stone in left ureter, opposite transverse process, third lumbar vertebra.

radiograph showed the presence of two stones in the left ureter (pelvic portion). The second showed the same stones with a bougie inserted past them. Upon close examination it was seen that the relations of the stones to each other had been slightly changed by the bougie. June 30, 1910, the husband wrote that his wife had a similar attack a few days after reaching home. He was anxious to have her operated upon. December 5, 1910, the husband reported that the patient had been having almost constant pain in the left renal region since July and he intended to soon have the stones removed.

On January 16 I operated on this patient, making an incision just to the inner side of the left rectus, drawing the rectus inward, incising the transversalis fascia, and stripping the peritoneum away from the pelvic wall. As the stones were not readily located, the peritoneal cavity was opened; the stones were grasped with the fingers in the peritoneal cavity and the thumb extraperitoneally, the ureter was opened with a fine pair of scissors,

and the stones were expressed. The stones were appreciably smaller than the shadows on the radiograph, measuring 3/16 by ⅛ of an inch. No attempt was made to close the ureteral opening, as it was quite small and deep in the pelvis, the stones being situated one inch above the bladder, a position somewhat lower than that occupied at the time the radiographs were made. Two cigarette drains were inserted and made to emerge through a stab wound just above the crest of the ilium in the posterior axillary line. Closure of the operation wound was made in layers. The last report is a letter of January 18 saying that the patient was making a good recovery. The drains were removed at the end of forty-eight hours.

Case IV.—Mrs. T. L. was seen June 4, 1910. She was twenty-six years old, married four years, and the mother of two children, two and three-quarters years and four months old, respectively. Normal labors. Her previous history was negative. The last menstruation was April 28, 1910. She was well until the fourth month of her second pregnancy. She had severe crampy pains in the left lumbar and inguinal regions which lasted eighteen hours. She was ill with pain and temperature for a week. After this she had some pain at times in both inguinal regions. She does not recall any bladder disturbance at this time. Three weeks after her labor she passed a small oval stone, the only pain occurring as this traveled through the urethra. Three weeks later she expelled another stone with only urethral pain. Since the passage of these stones she has had some pain in both right and left inguinal and lumbar regions, but this pain was never severe. For the past two months she has at times noticed in the urine a deposit which upon examination is found to be blood. Has lost some strength. Cystoscopy: The bladder and both ureteric orifices appear normal. A catheter passed into the left ureter meets with an obstruction which cannot be passed three inches from the vesical orifice. On the right side a similar obstruction is met with nine inches from the bladder. Radiograph shows two branch stones in the left kidney, one stone in the left ureter opposite the transverse process of the third lumbar vertebra, two stones in the pelvic portion of the left ureter, and one stone in the right ureter opposite the transverse process of the third lumbar vertebra. (The plate showing this was accidentally broken.) Clear urine flowed from the right side, bloody urine from the left. The patient is pregnant and refuses operation. Her only complaints are moderate and occasional pains and bloody urine.

METALLIC FOREIGN BODIES IN THE TISSUES; A NEW TELEPHONIC SEARCHER.

By WILLIAM S. THOMAS, M.D.,

NEW YORK.

SURGEON-IN-CHIEF, OUT-PATIENT DEPARTMENT, ST. LUKE'S HOSPITAL.

Women at their housework sometimes lose a fragment of needle in hand or foot and seek relief in the surgical clinic or at the hands of their physician who may make a futile attempt to find and remove the offending object and finally send the patient to the hospital where the help of a skiagram can be had. In the search for a metallic foreign body the skiagram is an invaluable guide and when it is available no operation of the kind should be attempted without its aid, unless the object sought for is unmistakably palpable through the skin. Even if so the incision is made cautiously and the parts handled gently in order to prevent pushing the foreign body from its position and losing it.

Operations for the removal of fragments of needles in the tissues are often provokingly difficult. In spite of a free incision and good retraction of the wound edges and a bloodless field, one may be reminded of the needle in the haystack. The eye is of less assistance than the finger in detecting the presence of a needle fragment. An infinitesimal amount of tissue between the foreign body and the surgeon's eye will conceal it whereas the sense

Fig. 1.—Fragment of needle in hand, shown by two skiagrams taken from different aspects.

of touch will reveal the object although covered by a layer of muscle or fascia.

If the fragment be small—say less than one-half of an inch in length—and is causing no inconvenience, it may be left alone with impunity. Skiagrams not infrequently reveal the presence of a

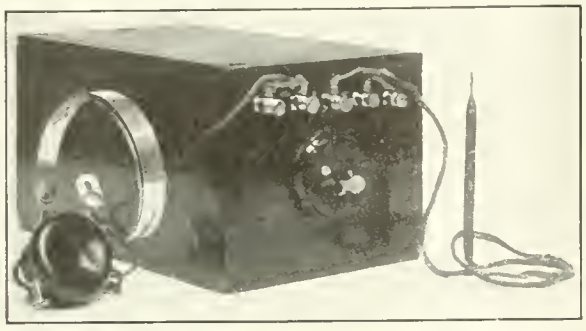

Fig. 2.—Telephonic searcher or probe at the right. Box containing two dry cells connected with telephone receiver at the left.

foreign body unsuspected by the patient. But as a rule muscular action, movement of the parts, or contact of the skin with outside bodies cause pain or discomfort and make removal necessary. Steel sewing needles are rather inocuous as sources of infection if left undisturbed. Perhaps their oxidation by contact with the body fluids is accompanied by the production of germicidal substances. Needle fragments on removal are found to have lost their polish and to be blackened even though but a short time has elapsed since their introduction.

If an operation be contemplated for the removal of a needle the parts should be immobilized between the time of exposure to the Röntgen ray and that of operation. Otherwise it is not uncommon for the small, sharp foreign body through muscular action, etc., materially to change its location.

Technique.—The usual preparation of the skin of the patient is followed by local anesthesia of the field and the application of an Esmarch's elastic bandage. With the skiagram as a guide, the incision is made as nearly as possible over the center of the needle fragment and at right angles to it, and should be long enough freely to admit the palpating finger for even when the operation is quite bloodless the sense of touch will detect the presence of the foreign body before it can be seen. Good retraction should be maintained. The incision is carried cautiously through the fascia, and as nearly as will be allowed by the nature of the parts should be continued in the same plane in which the knife first enters. If the needle lies in the substance of a muscle and parallel to its fibers it will be necessary, of course, to divide the muscle transversely. If, however, the needle seems to lie transversely to the muscle fibers, these may be separated bluntly and may not need to be divided. The ordinary probe is of little use as a searcher because by its means it is impossible to differentiate a number of natural objects from a foreign body when the latter is separated from the probe by soft parts of any kind. The knife edge is an excellent detector but must, of course, be used with caution as a searcher.

Once the needle is encountered it is immediately grasped with an artery forceps even though it is not completely exposed and though it may be necessary to grasp some soft parts with it. It is then pushed in the direction of its length until one end appears in the wound, when this in turn is grasped before the first hold is released and the fragment is removed. If attention to these details be not observed the fragment may be lost again or may be broken during its removal. Cautiously cutting, frequently feeling with the finger tip, good retraction, and a bloodless field are the essentials.

The occasional difficulties encountered in these seemingly trivial cases have led to the devising of an especial instrument to aid in finding fragments of needles or any metallic substances imbedded in the tissues. This consists of three parallel needles close together but nowhere touching each other and all secured in a handle. The needles are insulated from each other and each is connected with a wire of a three-conductor cord. These three conductors are connected with a battery of two dry cells and a telephone receiver in such a way that when once metallic contact is made between any two of the needles a sound is heard in the telephone receiver at the operator's ear. The illustration shows a box containing the dry cells and provided with switch and binding posts for connections. It also shows the telephone receiver with its head band and conducting cord and the searcher or probe with its needles in the hard-rubber handle. The plan of the writing is also shown in an illustration.

While the use of this instrument does not obviate the necessity of a skiagram, it is of material assistance in finding a metallic foreign body and has made easy what might otherwise be a tedious task. Once the incision through the skin has been made, the searcher is introduced if the anatomical relations permit of its use, and is carefully pushed to the length of the needles in the direction in which the foreign body is thought to lie. It is then withdrawn and is introduced parallel to and close by its first path until the neighborhood has been thoroughly searched. As will be seen, this instrument is used in much the same manner as the exploring

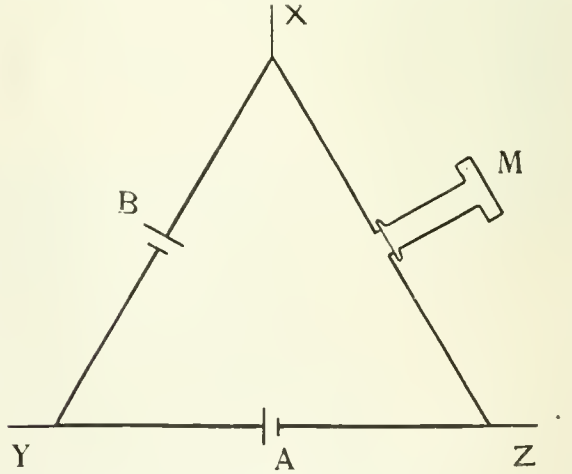

Fig. 3.—Plan of wiring telephonic probe. A and B, dry cells; M, telephone receiver; XYZ, the three insulated needles.

needle, though with a finer adjustment, as it were.

Once the sound is heard in the telephone receiver informing the operator that a metallic body has been touched, the switch is turned off, to prevent heating at the point of contact by the electric current. The searcher in place is left there as a guide and the foreign body is easily cut down upon.

The essential difference between this instrument and the older electric bullet probe lies in the fact that it is provided with more than two probing points and that these are sharp and will traverse soft parts independently of any sinus or wound of entrance.

EMBOLISM AND THROMBOSIS OF THE PULMONARY ARTERY.

REPORT OF THREE CASES—ONE OF EMBOLISM AND TWO OF THROMBOSIS.*

By JOHN FUNKE, M.D.,

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY IN THE ATLANTA COLLEGE OF PHYSICIANS AND SURGEONS, ATLANTA, GA.

Since I have nothing new to add, the only excuse for offering such a paper is to put on record one case of embolism and two of thrombosis, interesting in the light of recent surgical developments.

Case I.—G. M., age 30 years, was admitted to the Jefferson Hospital, December 2, 1903, in the services of Prof. W. J. Hearn, suffering with a right-sided inguinal hernia which developed two years before admission. On December 5, 1903, Dr. F. T. Stewart performed a Bassini operation and three days later the patient complained of pain in the right side, extending from the wound upward. On December 12, one week after the operation, at 1:45 A. M., the patient turned in bed to watch the action of a delirious neighbor. In a few minutes the patient was found in convulsions which were limited to the upper extremities; his legs were hanging out of bed, and in the course of ten minutes he was dead. At autopsy, fibroid myocarditis; embolus of the right pulmonary artery, thrombosis of the internal iliac vein, and hemorrhagic infarction of the right lung were found. The right lung was found to crepitate, except the inferior margin of the lower lobe. At a point fifteen centimeters below the interlobar fissure, near the posterior borders of the lower lobe, a slightly elevated reddish-black area, three centimeters in diameter, was found. This area cut easily, was wedge-shaped, and extended for a distance of two centimeters into the parenchyma of the lung. A similar but smaller area was found eight centimeters above the lower margin of this lobe, near the anterior border; it was four centimeters in diameter and elevated for a distance of one-half centimeter. The lower branch of the right pulmonary artery was filled with a dark red, friable, laminated mass, reaching to the bifurcation of the first branch.

Case II.—Z. was in the tuberculosis wards of the Philadelphia Hospital. The evening before his death a marked cyanosis of the face and neck, especially on the right side, and a marked swelling of the right arm developed. These changes were so sudden and extensive that rupture of an aneurysm into the superior vena cava was suggested at the bedside. Autopsy revealed widespread and advanced tuberculosis of the right lung. The greater portion of the upper lobe was occupied by a cavity. The tuberculous infiltration was especially marked about the root of the right lung and the pulmonary artery was apparently invaded. The right pulmonary artery was filled with a pinkish red, friable mass, which extended to the first subdivision. The microscope failed to reveal tuberculous areas in the arterial walls and in the clot, and tubercle bacilli were demonstrable in neither structure; nothwithstanding this negative finding I still believe that this thrombus was the result of a tuberculous infection of the artery and that my sections were taken at the point not invaded by the tuberculous lesion. I was unable to detect a venous thrombosis at any point. The sudden onset of the symptoms, I am inclined to believe, resulted from a sudden increase in the size of the thrombus that occurred when the heart began to flag. An interesting feature about this lung is the total absence of any consecutive effect of the thrombosis. There was not the slightest indication of infarction.

Case III.—D., age 35, was from the Insane Department of the Philadelphia Hospital and suffered with general paresis. There were no symptoms referable to the lungs prior to death. He suffered from gangrene, involving the great, second, and third toes, and part of the dorsum of the foot. Autopsy revealed a thrombus partially occluding the right pulmonary artery. The mass extended into several of the subdivisions of the artery, especially the upper branch. The thrombosis was in all probability the result of a terminal infection, the factor responsible for the thrombosis of those vessels causing the gangrene of the foot. The right lung failed to show an evidence of infarction.

The last two cases are of little interest, but the first is of importance, in view of the recent developments following embolism of the lungs. Trendelenberg was the first and his assistant the second to attack these cases during life. Trendelenberg's case died soon after the operation; his assistant's lived longer. Recently Kreuzer reported a case of thrombosis of the pulmonary artery with operation that lived five days. The patient was a rather weak woman, upon whom, on April 2, 1909, an operation for inguinal hernia was performed; there was no thrombosis at that time. While removing the adhesive plasters, on April 13, the patient drew up her leg and then suddenly threw both arms up, drew her head to one side, and could not be aroused. Her face was blanched, her pupils were dilated, and her pulse small; in about one minute the face became red and the pupils contracted. The patient smiled, but could not be aroused; the pulse became smaller and irregular, which was followed by cyanosis and dyspnea. The operation began twenty minutes after the onset of the symptoms. Kreuzer found the right pulmonary artery firm and, upon incision, found a black blood clot the size of a finger nail, upon the removal of which the heart ceased to beat, but was resuscitated by means of massage of the myocardium, after which the surgeon succeeded in removing a clot the size of a finger, when the heart again ceased to beat, and was again resuscitated by means of massage. The third search revealed no more clots. The hemorrhage was profuse, but the patient's symptoms were relieved. The autopsy showed, in addition to the suppurating wound, a left serofibrinous pleurisy; thrombosis in the left posterior lower pulmonary branch, in the posterior branch of the upper lobe, and in the right pulmonary branch. The upper half of the lower lobe contained dark red depressed areas. There was thrombosis in the iliac and hypogastric veins. Kreuzer is inclined to believe that the patient would have recovered had not infection occurred at the time of the operation.

Of the 3,334 cases of appendicitis in the London hospitals twenty-nine showed thrombosis, seven of which gave rise to pulmonary embolism. Of the fourteen fatal cases of embolism following gynecological operations or labor, Mahler saw twelve at autopsy, and ten of these showed diseases of the myocardium. It is, of course, possible that the changes in the heart found in these autopsies are a coincidence, yet it is also probable that a lesion in

*Read before the Philadelphia Pathological Society April, 1910. From the laboratories of the Jefferson Medical College Hospital, Philadelphia, Pa.

the structure may be a factor in the production of thrombosis. Oppenheim calls attention to the fact that in many surgical cases toxins may act deleteriously upon the heart muscle, which weakens that organ, resulting in retardation of the blood current, causing incomplete emptying of the ventricles and auricles. He also points out that as the result of peritonitis or tympanitis the diaphragm is pushed upward, diminishing the thoracic space, and with it the expansive capacity of the lungs, as the result of which the suction influence upon the venous blood column is proportionally diminished, and consequently there is a diminution in the return flow of the blood, which, of course, leads to a slowing of the current. It is fairly well established that the mere slowing of the circulation is insufficient to cause thrombosis and that trauma is insufficient, but the fact that the veins in the neighborhood of the operations are so frequently involved would suggest that some damage is done at the time of the operation which is instrumental in producing thrombosis. A factor that should not be passed unobserved is the alteration of the viscosity of the blood during the operation. While a resident in the Jefferson Hospital Dr. Landry carried out a series of experiments to determine whether the viscosity changes during operation. He found that in some cases the blood became more viscid and that this change seemed to go hand in hand with the amount of perspiration. In one case he found that before the operation the viscosity was 5.2, after the operation 5.4; in another 4.4, after the operation 4.7; in a third 4.7, after the operation 4.9; in a fourth 3.3, after the operation 3.8. An increased viscosity of the blood undoubtedly throws more work upon the heart, which is an additional factor in diminishing the force of this organ, inducing retardation of the current. As yet we have no way of knowing whether or not with an increase in viscosity there is a destruction of the formed elements of the blood. Should such changes occur, they would undoubtedly be a very important factor in the production of thrombosis. In such substances as laked blood and cell extracts, especially lymphoid cells, the coagulated principle is thought to be a neucleoprotein liberated from the cell stroma which unites with the calcium salts to form the fibrin ferment. Silverman and others maintain that the destruction of the red blood cells by such poisons as anilin, potassium chlorate, arsenic, phosphorus, corrosive sublimate, carbon dioxide, and carbon monoxide, plays an important part in the production of thrombosis. In this connection Duckworth observed that carbonic acid, ether, and chloral hydrate increase the viscosity of the blood, which condition may predispose to the formation of thrombi. Marantic thrombi, he thinks, occur without the intervention of microbes. Milk rich in lime salts induces superfibrination, and he suggests that this diet may be responsible for the frequency of thrombosis in typhoid fever. One can readily understand that the destruction of the formed elements, especially the erythrocytes, may occur with the alteration in the viscosity of the blood, which undoubtedly is dependent upon the extraction of the fluid elements of the blood, producing hyperisotonic condition of the blood, in which medium the red cells may disintegrate. The probabilities are, however, that an important factor in the production of the thrombosis following operation is the trauma that results incident to this procedure, and that slowing of the current and alteration in the viscosity are factors, the former necessary, the latter incidental and contributory. Baumgarten has shown that a vessel may be ligated without the production of thrombosis, and, of course, on each side of the ligature the current is not only slowed, but is stagnant.

Von Rechlinghausen attached more importance to the whirling motion than to a mere slowing of the circulation. These whirls are produced when the small vessels empty into large ones, or into cul-de-sacs. According to Ebert and Schimmelbusch, the blood platelets under normal conditions circulate with red cells in the axial stream, but make their appearance in the outer zone when the current is diminished. Moderate slowing is attended by the accumulation of blood platelets in the peripheral stream, and further slowing is attended by the accumulation of leucocytes and more platelets in the circumferential stream, but thrombosis does not occur until the intima of the vessel has suffered a change. The accumulation of the leucocytes and blood platelets, accompanied by a viscid metamorphosis, leads to the liberation of the thrombokinase which acts upon the prothrombin, converting it into thrombin, which substance, in the presence of calcium salts, acts upon the fibrinogen, converting it into fibrin. Briggs refers to a case of recurrent thrombosis in which the coagulation time was very short owing to the presence in the blood of fluorine, which was found in the beer the patient drank.

Bacteria undoubtedly play a rôle in the production of thrombosis. Kratz states that the most important conclusion to be drawn from his post-mortem material is that he never failed to find an associated infection in the emboli of the pulmonary artery. In discussing the subject, he mentions as a source of these emboli inflamed hemorrhoidal vessels, inflamed veins of the skin, resulting from excoriation, and inflamed follicles, although he maintains that it is not always possible to find an inflammation of the wall of the vein although infection was nearly always present, because he was dealing with individuals who were just convalescing or had just recovered from an acute infection. According to his experience, pneumonia and erysipelas are more frequently and typhoid fever less frequently complicated with thrombosis or embolism of the pulmonary artery. Kratz, in attempting to explain Baumgarten's failure to produce thrombosis by the aseptic ligation of a vein, holds that there was no infection, consequently no bacteria nor toxins to produce a precipitation of the fibrin. Welch holds that extensive aseptic experimental injury to the vessels may fail to produce thrombosis, whereas, if infection be present, thrombosis occurs. In studying the vessels of cases of acute infectious diseases, Welch found collections of lymphoid and endothelial cells in the subintimal structures. The frequency with which bacteria were missed in these collections led him to believe that the toxins of acute infections are important factors in the production of thrombosis.

Ponfick long ago called attention to the degeneration of the endothelium of the vessels in acute infectious diseases, and Widal has suggested that a search be made for bacteria in all thrombi, especially those accompanying the puerperium. The thrombosis is usually produced by some secondary infection and not by the organism causing the primary disease which is complicated by the thrombosis, although Flexner and Welch have reported a case of pulmonary thrombosis complicating influenza, in which Pfeiffer's organism was found in the clot. Streptococci and other pyogenic bacteria are the fre-

quent secondary invaders. The various bacteria have different powers in producing thrombosis. For instance, the *Staphylococcus pyogenes albus* is more powerful in this respect than the colon bacillus. These properties of the bacteria are greatly reduced when the organisms are heated, so that it is not a mere mechanical effect incident to the irritation of the bacteria or their toxins. The part played by the blood platelets in the production of thrombosis has occupied the time of many observers. With regard to the origin of these elements opinions are not in accord. By many investigators they are held to be altered cell forms or cell derivatives, and hence a destruction in the formed elements of the blood leads to an increase in the blood platelets. There seems to be much in favor of the view that an increase in the blood platelets is an index to the lowered resistance of the red blood cells, and it is very probable that the blood platelets are one, but not the only, source of the thrombokinase.

Eberth and Schimmelbusch insist that the first evidence of thrombosis is an accumulation of the preexisting blood platelets upon a foreign body or damaged vessel wall. Contact with an abnormal surface sets up an immediate viscous metamorphosis of the platelets whereby they adhere to one another, to foreign bodies, or to injured vessel walls. These investigators, by rendering noncoagulable dog's blood through the injection of peptone, produced blood platelet thrombi. Sahli and Eguet, on the other hand, failed to produce thrombosis by introducing hog's bristles or silk thread into the jugular veins of rabbits, the blood of which was rendered noncoagulable by leach extract.

STERILIZATION OF THE SKIN BY A NEW IODINE SOLUTION.

By ELLICE McDONALD, M.D.,

NEW YORK.

Sterilization of the skin by iodine, since its advocacy by Grossich,[1] has been received with enthusiasm by a large number of operators. Grossich used the tincture and painted it on the surface of the skin without any preliminary washing. He first used the method upon lacerated wounds, and later extended it to the preparation of the abdominal skin for operation. The preparation used was the 10 per cent. (Italian) tincture. Since his first report[2] he has collected 2,284 operations in which the method was employed, and Gulbé,[3] Hesse,[4] Bogdan,[5] Pers,[6] Unger,[7] Stone,[8] Jewett,[9] Streitberger,[10] and others have reported good results with his method. Grossich advised that the skin should not be washed beforehand, as the water swelled up and softened the superficial layers of the skin so that the iodine did not penetrate the tissue. It also seems that the irritative action of iodine is more marked after water has been applied. He also advised two coats of the tincture, but this has been changed to a single application by most of those following him, as the skin sometimes suffers irritation from the repeated application. Even when one coat is applied, numerous instances of skin irritation and blistering have been reported.

Heusner[11] was one of the first to advise the iodine sterilization of skin surfaces, particularly of the hands before operation, and advocated a solution of a 1:1000 of iodine in benzine. While this solution is too weak, it has certain advantages in that the iodine is present in a fat-dissolving solution which is comparatively unirritating. The investigations of Laiacono[12] prove that the alcoholic solution of iodine (the tincture) penetrates the epidermis more slowly than does a solution of iodine in a fat solvent (acetone). He conducted a series of experiments upon guinea pigs and found that there was complete penetration of the entire cutis, with diffusion into the subcutaneous tissues when the iodine was suspended in acetone. He also stated that in certain cases the tincture tended to cause diffuse infection from its irritative action, and that certain bacteria such as bacillus diphtheriæ were destroyed in test tube experiments, but not affected while growing on the skin. These reports make it evident that, while Grossich's method is good, it is not ideal, and offers a few disadvantages. One of these is the irritative action shown occasionally by the 10 per cent. solution. A number of operators, as Stretton,[13] Waterhouse,[14] and Fenwick, have reduced the percentage of iodine in the alcohol to 2 or 2.5 per cent., and have reported series of operations with equally good results. A second disadvantage is that the alcoholic solution of iodine is a poor fat solvent and for this reason does not penetrate the epidermis. Several operators have advised, for this reason, the preliminary washing of the field of operation with ether in order to wash the fat out of the crevices of the tissues and allow the penetration of the iodine, but this again begins to complicate the method. Again, Grossich's excellent technique has the disadvantage that the tincture must be painted over the skin with a brush or gauze, and it is not possible on account of its irritative action to rub it in and thus obtain the valuable aid of mechanical cleaning so useful in the preparation of the hands before operation. This application of the tincture has also the disadvantage of leaving the skin painted to the edge of the wound with an irritant some of which may be carried into the wound to irritate the peritoneum. While this is not a proven fact, it is something every operator must fear while doing an abdominal operation with the skin cleansed by the 10 per cent. alcoholic solution.

After Heusner, in 1906, first reported the good results with his solution of 1:1000 iodine in benzine, I began a series of experiments to obtain a comparatively unirritating solution of iodine in a fat solvent in greater proportion than 1:1000. Benzine will not take up more than that amount, and the solvent itself is rather irritating to the skin. After a number of experiments with various solutions and combinations of alcohol, chloroform, benzine, acetone, ethylene dichloride, toluene, glycerin, and carbon tetrachloride, the following mixture was found to be the best: *Iodine, 2 parts; carbon tetrachloride, 98 parts.* This solution has been used in my work for three years in abdominal operations with uniformly good results and without any skin suppurations whatever. The abdomen is shaved the night before operation and washed with gauze (no brush), and an antiseptic soap, such as mercuric biniodide soap or a formalin soap made up of 5 parts of formalin to 15 parts of benzine and 80 parts of tincture of green soap. A soft, dry, sterile towel is then applied over the field of operation. At the operating table this towel is removed and the carbon tetrachloride-iodine solution is swabbed on the skin surface of the abdomen, and rubbed into the skin with a piece of gauze for between one and two minutes, the time being taken by the anesthetizer. The mixture dries readily, leaving the skin ready for the incision. This mixture combines the

advantages of Grossich's tincture of iodine method and v. Herff's[15] alcohol-acetone method of disinfection of the skin. The carbon tetrachloride is a fat solvent, which alcohol is not, and the addition of the iodine makes it a more powerful antiseptic than the alcohol-acetone of v. Herff. Carbon tetrachloride is in itself an antiseptic of considerable value and is useful in preserving urine in place of chloroform, and has been used to preserve diphtheria antitoxin. Carbon tetrachloride ($C Cl_4$) is a heavy anesthetic liquid, not unlike chloroform, with considerable odor, and a fat solvent. It does not burn or explode and is comparatively unirritating. My attention was first directed to it by advertisements of a cleansing solution for taking grease spots from clothes, advertised under a trade name which is a corruption of the first part of its name, and as a substitute for explosive benzine.

The advantages of the carbon tetrachloride-iodine mixture are its simplicity and fat-dissolving properties. If used repeatedly upon the hands, the skin will become dry and peel off, but this will not happen unless there is repeated application, and I use it after my hands have been in pus, or after a pus case has been operated upon, to be sure of complete sterilization. For constant use as a hand disinfectant, the iodine must be reduced and some lotion or oily substance, as lanolin or cold cream, rubbed into the skin of the hands after operating. Carbon tetrachloride is not expensive and costs in the neighborhood of two dollars a gallon, and three ounces is sufficient to prepare the abdomen for operation.

The recent operations of Post and Nicholl[16] show that iodine in aqueous solution of 1 to 400 is efficient in killing all organisms in less than one minute, and that iodine is one of the best germicides. The aqueous solutions have the disadvantages, however, of not dissolving fat, of not penetrating and of not readily evaporating. There is a great deal of ignorance in regard to the value of surgical antiseptics, which these investigators have helped to clear up. Bichloride of mercury in an aqueous solution of 1:2000 will not kill the streptococcus in 30 minutes, so of what use is it to irritate one's hands by plunging them into this solution for one minute? The naive and blissful belief some operators have in the germicidal value of bichloride of mercury for skin surfaces would be amusing were it not pathetic. Harrington's solution of alcohol, hydrochloric acid, and bichloride of mercury is, of course, an efficient germicide on skin surfaces, but it is irritating to most skins.

The fat-dissolving antiseptic solution of carbon tetrachloride and iodine 2 per cent. is a useful antiseptic, unirritating and easily applied. It has the advantage of v. Herff's alcohol-acetone mixture and of Grossich's tincture of iodine method. If it is desired to completely seal the skin, it may be done by solutions of resin in carbon tetrachloride as chirosoter of v. Herff, a solution of wax in carbon tetrachloride, or the following solution: Benzine and resin damar, of each 10, ether 100, thymol 0.5. However, this is not as a rule necessary, unless to cover some adjacent suppurating or recent wound.

In the sterilization of the skin, the value of antiseptic soaps and of spirits of soaps, as shown by Post and Nicholl, by Schumberg,[17] and by Lenzmann,[18] should be kept in mind; but the skin should be allowed to dry before iodine solutions are applied, as these will not penetrate and, in the case of the tincture, irritate the skin. It is believed that the carbon tetrachloride-iodine solution is an efficient substitute for the tincture of iodine in the preparation of the skin for operation.

REPORT OF A CASE OF CONGENITAL CYSTIC DEGENERATION OF THE KIDNEY.*

By H. BROOKER MILLS, M.D.,

PHILADELPHIA.

ASSISTANT PROFESSOR OF PEDIATRICS IN THE MEDICO-CHIRURGICAL COLLEGE, ASSISTANT PEDIATRIST TO THE MEDICO-CHIRURGICAL HOSPITAL; PHYSICIAN TO THE NORTHERN HOME FOR FRIENDLESS CHILDREN, PHILADELPHIA.

As the title of this paper indicates, my object is simply to make a report of an unusually interesting case of congenital cystic degeneration of the kidney, and not to discuss the subject itself at any great length, partly because so little seems to be known about it, and partly because the literature on the subject is so scant.

J. B., aged 14 months, was admitted to the wards of the Medico-Chirurgical Hospital on June 28, 1910, in the service of Professor Hollopeter through the out-patient department. The family and previous history of the patient were negative, and apparently the only abnormal condition present was an enormous growth on the left side of the abdomen, which the mother stated had commenced seven months before, when the child was seven months old, and had been steadily progressing.

Three blood examinations were made, the first on July 7, showing reds 6,200,000, whites 11,800, and hemoglobin 70 per cent. Five days later the reds had dropped to 4,220,000, while the leucocytes had increased to 14,600, and the hemoglobin to 75 per cent. Six days later the reds had increased to 4,600,000 and the leucocytes to 17,600, while the hemoglobin had dropped to 70 per cent. The analysis of a catheterized specimen of urine showed a small ring of albumin, no sugar or indican, and microscopically narrow and broad hyaline casts, and a coarse, granular cast, with a few urates, leucocytes, and epithelial cells. Photographs were taken by Dr. George E. Pfahler, radiologist to the Medico-Chirurgical Hospital, but, except for making certain that the

*Read before the Philadelphia Pediatric Society, December 13, 1910.

growth was not an enlargement of the spleen, as had been suspected, the photographs were negative.

After remaining in the hospital three weeks the child was operated upon by Prof. William L. Rodman, assisted by Drs. J. Stewart Rodman and Stillwell C. Burns, for removal of the growth. A section of the specimen removed was examined in the pathological laboratory, and the pathologist's report proved it to be a case of congenital cystic degeneration of the kidney. Convalescence was uneventful, and the child was discharged from the hospital one month after the operation, at which time it was in good condition. It is interesting to note the variations in the blood examinations, the reds almost uniformly diminishing, the whites rapidly increasing, and the hemoglobin remaining about stationary.

In addition to the rarity of this disease, two other points are important to notice: First, the uniformly unfavorable prognosis of all cases as claimed by most writers on the subject, either with or without operation, and, second, the difficulty in making a positive diagnosis before operation. At least a half dozen competent men examined this case, and we were aided also by the photographs taken by Dr. Pfahler, as well as the blood reports, uranalyses, etc., but, in spite of these aids, the real condition remained undiagnosed. The three conditions suggested as being the probable cause of the trouble were enlarged spleen, hypernephroma, and sarcoma of the kidney, all of which proved to be incorrect.

In looking up some of the text-books on the subject I find that Cotton says: "Congenital cystic degeneration of the kidney is presumably due to developmental arrest or perversion in the embryonic tubules, with the formation of terminal pouches. These subsequently fill with fluid and may attain enormous dimensions, rendering delivery difficult or impossible. One kidney alone is rarely affected. These cysts, although usually multiple at birth, develop rapidly with a tendency to coalescence and obliteration of all normal histological structures. When discovered they appear as abdominal tumors, with evidences of renal insufficiency. If both kidneys are involved, differentiation from hydronephrosis and malignant tumors may be assumed from the bilateral character. Most frequently the infant does not long survive birth, although these tumors develop slowly until adult life. The true nature is usually revealed at the post-mortem. No curative measures are of any known value."

Ruhräh does not mention the subject of congenital cystic degeneration of the kidney at all, referring only to sarcoma as being by far the most common form of growth in the kidney, and being present almost always (as in our case) in the left kidney. Koplik devotes but a few lines to the subject as he considers the condition to be of "anatomic and scientific interest only, since infants with such cysts present other abnormalities and die soon after birth." Holt reports having seen three cases and "the ages at which the children died were from 7 to 10 months. No renal symptoms were present." Reference to a number of other text-books on Pediatrics failed to reveal any mention of the condition.

Inquiry since the writing of this paper disclosed the fact that the patient lived only one week after leaving the hospital, in other words, five weeks after the operation, its death being due, according to the attending physician, to consumption, although of what part of the body I do not know.

1411 Spruce Street.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.*

By ROBERT H. M. DAWBARN, M.D.,

New York.

How Best to Measure for Shortening of the Femur.—The way regularly taught is a mistake—measuring, that is, from ant.-sup. spine of ilium to one or other malleolus tip; a mistake because we should never measure over a needless distance. In this case we add to the problem (and without being obliged so to do) the possible difference in the length of the two limbs below the knees. There are three better methods: (1) Measure from the anterior-superior iliac spine to the adductor magnus tubercle. This is good so far as it goes; it does not, however, measure the entire length of the femur. (2) Measure from the anterior-superior iliac spine to the lowermost point or apex of the patella—drawn up firmly for this purpose. (The level of the knee-joint is the apex of the patella.) (3) The writer's method. Place the patient flat on his back upon any firm surface. Flex both thighs, placed side by side, to a right angle with the body; that is, they are now vertical. The legs, in turn, are flexed to a right-angle with the thighs; that is, they are now horizontal. The difference in height of the two patellæ will now indicate the exact degree of shortening, if any, of the femur under examination.

The Simplest Camisole.—It is, of course, best not to bind down a violent patient, when gentle hand restraint is available, to avoid injury either of himself or attendants. But sometimes mechanical control is alone practicable. This being so, it is well to know what is alike the simplest and most merciful form of camisole. To make this, thereby compelling a reasonable degree of quiescence of the upper extremities, prepare two cylinders, about the shape of long shirt sleeves, by hemming together stoutly the two long edges of a pair of towels. Sew these new sleeves to the ends of the sleeves of a nightshirt. When the patient is clothed in this the sleeves, of course, drop a long way below the hands. Fold his arms; bring these extension-sleeves tightly across his back and past each other. Secure them thus either by sewing or by large safety pins.

Breath.—Lose this and you are done! These six letters cover as a mnemonic the chief causes of operative shock. None of you who read this will ever forget it; without, in time, you might sprain your mind, and still fail to recall them all unless you are an experienced surgeon. I am a firm believer in the real helpfulness of such memory-aids

B. Bleeding: First, and by far the most important cause. Upon the extremities, cord always before cutting. Upon trunk, neck, or head, use "sequestration anemia."† Remember your anatomy; find and tie big vessels before, not after, cutting them. *R.* Roughness: Be gentle. In various regions rough handling invites shock. *E.* Excitement: Just as bad news occasionally kills

*See Medical Record, April 1, 1911.

†See Medical Record, March 4.

instantly, from shock, so personal anxiety as to death under the knife invites this to some degree. Hence the wisdom of a preparatory hypodermic an hour or so before the operation—sending the patient to it in a somnolent state; one of mental calm and content. Gr. ¼ morphine sulph., gr. 1/150 each of atropine sulph. and scopolamine hydrobrom., proves a very effective and safe combination for this purpose. I have used it before any major work these many years, and before all forms of anesthesia. *A.* Anesthesia: In excess invites shock.* Snoring, which means paralysis of the velum pendulum palati, is, except in rare instances, a sign that the drug has been pushed a little too far for safety. Try to avoid this. *T.* Time: Is of vital importance. Waste no precious minutes talking or lecturing while your patient is under major anesthesia. Again, when the speeding and weakening pulse indicates probable shock unless the operation be quickly discontinued, *part your operation in the middle.* That is, stop there and then. Pack the wound lightly and finish, even days later, if need be. *H.* Heat-loss: Remember that a long ether-anesthesia may cause a drop of two degrees F. Avoid adding to this risk of shock-production chilling from any other cause.

Whether for Bleeding or for Saline Infusion, use by preference the internal saphenous vein, between knee and ankle. There are a number of reasons for its choice, and none against it. (1) It averages as large, and is as easily found, as the vein usually chosen at the bend of the elbow. (2) Even a careless operator cannot do serious harm. If reckless, only the accompanying sensory nerve could be cut, whereas at the elbow many times the brachial artery has been divided. Indeed, this is, in consequence, the commonest seat of aneurysmal varix and varicose aneurysm. Of course, if the internal saphenous vein be entered in the thigh, not even the nerve of the same name is endangered. However, there one has to go considerably deeper in the fat to find the vein than when the leg is chosen. By-the-by, the internal saphenous nerve is, until it has reached as low as the kneepan, very badly named; for it is, in Hunter's Canal, the deepest of the structures therein contained. In the leg alone is it "saphenous" (conspicuous or manifest) because superficial. The vein of the same name, which we have been discussing, is properly named its entire length, on the contrary. (3) The scar will be in an unobjectionable region. This cannot be said if the arm is chosen. (4) The assistant doing saline infusion is probably not in the way of the main operation. He does not bother, as a rule, the surgeon and his assistants, who save time by proceeding with their work meanwhile. Upon the arm this would hardly be equally true, in most cases. For many years past I have invariably had one leg shaved and sterilized prior to any major operation, to be ready in case saline infusion should become necessary during the operation, in order to prevent shock—should the symptoms indicate that this condition is threatening to develop.

In many cases the vein, whether at elbow or leg, can readily be entered without cutting—using simply a long, coarse, hypodermic needle.

Recipes for Remembering the Cysts.—Many experienced teachers respect, devise, and use, more or less, aids to the memory. Some of these mnemonics in our profession are known to be hundreds of years old. Oliver Wendell Holmes and Corydon L. Ford are, among anatomists, conspicuous instances in point. During the middle ages it was considered bumptious and insufferably conceited to attempt to improve upon the teachings of Hippocrates, Galen, and sundry others of the Grandfathers of Medicine; and able instructors spent much time in devising, instead, ways of helping to remember the golden sayings of the past. As a single modern instance, take the following simple way for bearing in mind all the varieties of cysts. Once read, it will stick, as a matter of course. Without some such help I do not believe this would be so. Remember them by the word "Recipes":

R. Retention; example, the sebaceous cyst. *E.* Extravasation; example, the hematocele. *C.* Congenital; example, the branchial or the dermoid cyst. *I.* Irritation; example, bursitis, housemaid's knee. *P.* Parasitic; example, echinococcic cyst. *E.* Exudative; example, ovarian cyst—or hydrocele. *S.* Softening; example, from softening of the brain.

Note on the Relationship of the Veins.—Above the diaphragm the vein is either upon the same horizontal level with its artery (that is, horizontal, with the patient lying upon his back), or else lies *in front* of the artery. Below this level the vein lies either upon the same plane or else *behind* its artery. To this rule—covering the relationship of very many vessels—there are but five exceptions; and none of these is of practical importance. Hence the fact is worth remembering by the operator. But below the axillary and below the popliteal vessels all veins of the limbs accompanying important arteries are double; they lie as a rule upon either side of the artery.

"The" Jugular Vein.—Considering how often "the" jugular is reported in the newspapers as cut, by accident or otherwise, it might be well for the sake of clearness if more young doctors remembered that every human being possesses eleven jugular veins; that is, if we include the two oblique jugulars, running down along the sternocleidomastoid muscles, regularly included by some writers, but considered only occasionally present by others. Also, of the small transverse branch, or transverse jugular, connecting the two anterior jugulars, the same thing may properly be said.

Do You Mean to Become a Surgeon?—Then indeed your knowledge of anatomy becomes as your right hand among professional requirements. Make this a rule never to be broken: Devote fifteen minutes every day to its study. By concentration, it is wonderful how much refreshment of knowledge can be packed into a quarter of an hour. P. S.—This is not intended to discourage you from making it half an hour daily.

Hope on, Hope Ever!—Never admit even to yourself that any patient still capable of drawing breath is impossible of recovery. With his soul hesitant as to flight, to the conscious patient desperation sometimes lends keenness; and he can often read despair in the surgeon's eyes if it is there. This takes away his courage, and loses many a battle otherwise still capable of having a different ending.

105 West Seventy-fourth Street.

*Ether and chloroform tend to invite shock by deleterious effects upon the blood. This is not true of laughing-gas, with or without oxygen.

Priapism in Leucemia.—F. E. Stanjeck reports a case of leucemia complicated with gonorrhea in which priapism was controlled with improvement of the blood following *x*-ray treatment. This is not always the case.—*Dissertation Leipzig.*

VAGARIES OF MODERN VACCINATION IN THE UNITED STATES.

It is a fact generally overlooked by the laity and practically ignored by the profession that vaccination, as performed in the United States at the present day, provides but a slight guarantee of protection from a possible epidemic invasion of smallpox. The example of progressive European countries, particularly of Germany, in the institution of compulsory vaccination has had but slight influence in the countries speaking the language of Jenner. It is noteworthy that at times when smallpox was raging throughout Europe, Germany, which had adopted a system of universal compulsory vaccination, was practically free from the disease. That voluntary vaccination is not a sufficient safeguard is indicated by recent epidemics of smallpox in different parts of this country. In 1906 George Dock pointed out the fact that of 2,000 patients that had been admitted to his wards in Michigan only 60 per cent. had been vaccinated. At a time, like the present, when the public enjoys a sense of security in the belief that smallpox can never attain epidemic proportions such as prevailed in former years, it is necessary to point out a few facts to indicate upon what unstable foundations this belief is established.

The absence of any definite and systematic organization of public vaccination relegates this practice to the carelessness of the public and the indifference of physicians, who are aroused from their lethargy only by an occasional local outburst of smallpox. No one will deny the necessity of the enaction and enforcement of adequate legislation for the safeguarding of life from fire, yet the awful calamity of epidemics that can easily be prevented does not impress the community with equal force even when the epidemic is in the midst of us. The example of New York and Chicago in requiring a certificate of vaccination in the case of all children admitted to school has been cited as a sufficient means of compelling public vaccination. Although better than none, this measure is of illusory value as an efficient sanitary regulation. It reaches the native-born population of these cities and the children of immigrants, but it has no effect on the foreign-born adult population. Moreover it creates the general erroneous impression that it is necessary for a child to be vaccinated only once in early life to be permanently immune to smallpox. School authorities place themselves in the anomalous attitude of compelling vaccination in early life, but practically ignoring the necessity of this procedure at a later age. If a child has been vaccinated when one year old it is admitted to school at the age of six, but a few years later its immunity to smallpox may have vanished. Therefore from the age of eight to the age of eighteen, at the end of the high school period, practically all the school children are without adequate protection. A recent investigation among the students of one of the largest high schools in New York City revealed the fact that the large majority of students, whose ages ranged from thirteen to eighteen, had not been vaccinated since early childhood.

If the influence of educational authorities is to have any weight in the effective control of vaccination a definite system must be adopted, with the following as necessary features: The certificate of vaccination presented when the child is first brought to school must state exactly the date when vaccination was last performed. A certificate that merely states, as in the case of certain printed forms used by physicians, that "this is to certify that I have this day successfully (?) vaccinated ————," should not be accepted. Evidence of a successful vaccination should be clearly demonstrable to the school physician before a child can be admitted. The date of the last vaccination should be recorded in the case of every pupil, and revaccination should be required no later than seven years following this date, and if the child is still in school, at a period seven years later. Evidence of vaccination performed within a preceding period of seven years should also be required in the case of all minors and adults applying for admission to evening schools, technical schools, and colleges; and of all applicants for teachers' licenses. Only by a system embodying provisions like the above can effective vaccination among the school population be assured.

Such measures, however, cannot reach the greater part of the adult population which is practically unvaccinated, despite the popular notion that vaccination in childhood confers lasting immunity. The experience of the present epidemic in London as reported by our London correspondent, March 25, 1911, forcibly illustrates this point. Of forty-nine cases of smallpox reported, thirty occurred after the age of eight years, in individuals of whom two had never been vaccinated and of the remainder none had ever been revaccinated since early infancy. These figures eloquently proclaim the dangers to which the large unvaccinated adult population are exposed.

These dangers will persist until the government adopts a system of compulsory public vaccination with registration of the date of every inoculation performed. In this connection the example of Germany may again be cited. The German law compels vaccination at the age of two years, again at the age of twelve, and all recruits, who comprise all males between the ages of eighteen and twenty, must be revaccinated. Although this law is not a model one, reaching only a portion of the popu-

lation, it is infinitely better than the modern haphazard practice of voluntary vaccination, because, in addition to its compulsory provisions, it recognizes the necessity of revaccination.

THE MODERN TREATMENT OF TUMORS OF THE BLADDER.

The recent extraordinary developments in the technique of cystoscopy have practically revolutionized the treatment of tumors of the bladder, particularly of the benign variety. In most instances, with the aid of proper instrumentation, the latter may now be attacked easily by the endovesical route. Suprapubic cystotomy, except in the case of circumscribed malignant tumors of the bladder wall, in the early stage, and in the case of extensive benign tumors, is no longer to be regarded as an operation of choice. These facts are emphasized by Georges Luys of Paris, who in a contribution in *La Clinique*, March 3, 1911, describes the advantages of his direct vision cystoscope both for diagnostic and therapeutic purposes. The making of an exact diagnosis of the presence of a tumor, and of its exact size, location, and nature, is imperative as a preliminary to the operation of endovesical extirpation. Luys points out the diagnostic advantages of his direct vision cystoscope over the types of instrument provided with a prism, which advantages are particularly apparent when the field of vision is obscured by the escape of blood in the interior of the bladder.

From the viewpoint of treatment, the eminent French surgeon alludes to the complexity and difficulty in the use of Nitze's operating instrument. In addition the latter is employed with the bladder distended with water, which has the effect of reducing and shortening the incandescence of the platinum electrode. With Luys' instrument the operative maneuvers are directly under the control of the eye, and the cauterization is more precise, intense, and effective, and naturally of much shorter duration.

The advantages of endovesical over suprapubic extirpation of benign vesical tumors are many; the operative dangers are practically nil; the inconvenience of general anesthesia is obviated, together with the long rest in bed after the operation, and the latter may be performed in the surgeon's office. Moreover, the endovesical operation is more thorough, the bladder when stretched permitting an adequate inspection of its interior and bringing to light small tumors that would escape observation in the suprapubic operation. The ease with which the endovesical operation may be performed makes this treatment of eminent value in the case of recurrences, which are particularly frequent in papilloma.

The hypogastric route is to be elected under the following conditions: when the urethra will not permit the introduction of an instrument sufficiently large; when the tumor is of great size, as in the case of certain fibromata; in the early stage of malignant growths when these are sharply circumscribed and localized; in the later stages of the disease, when the bladder wall has been infiltrated and the tumor has attained a great size, even suprapubic extirpation is not only of no avail, but hastens the fatal termination.

Legislation in the Interest of Higher Medical Education.

A bill is now before the Illinois Legislature which introduces a novel and most commendable feature in medical licensure that might well, in the interest of higher medical education, be imitated in other States. It is entitled Senate Bill No. 235, and introduces two amendments to the existing law regulating the practice of medicine. The amendment to which we would call attention provides "that the State Board of Health may, in its discretion, admit to examination a student who has completed, in a medical college determined in good standing, the course of instruction required by the rules of said Board in medical colleges determined in good standing, and who has passed the examinations of said college, but has not received a diploma. And if said student pass the examinations of the said Board it may issue to him a limited license authorizing him to practice medicine and surgery in a hospital approved by said Board and in no other place whatsoever in the State of Illinois, which limited license shall remain in effect for a period not exceeding eighteen months from the date thereof, and the State Board of Health may then issue to the applicant the regular permanent license of the Board without further examination or fee, on condition that the applicant present a diploma from the medical college in which he had completed a course, as prescribed by the rules of the said Board, previous to the issuance of the limited license hereinbefore mentioned, and otherwise complies with the requirements of the Board." This section, as Dr. Egan states in the March Bulletin of the Illinois State Board of Health, is the outcome of a request made of the State Board of Health by a leading medical college of Illinois to secure legislation that will enable its students to practice with legal sanction in a hospital during the fifth—clinical—year, which the college desires to add to the present curriculum. The requirements of the State Board of Health demand a course extending over four calendar years. This college purposes to adopt a course extending over five calendar years. This bill does not increase the requirements now demanded of medical colleges, but it is a step in the direction of higher medical education and may eventually lead to the universal custom, if not the necessity, of a student passing a year in hospital practice before receiving a general license to practise medicine in the State and is therefore in the interests of the health of the community. It is to be hoped that this bill will be passed, and that the example of Illinois will be followed by other States.

Orrhodiagnosis and Serotherapy of Gout.

It is now well known that many chemical substances, whether of bacterial origin or not, may form antibodies in the blood. A toxin produces an antitoxin, a ferment an antiferment, etc. Falkenstein, at a very recent meeting of the Berlin Medical Society (*Münchener medizinische Wochenschrift*, February 21), discussed the subject of a possible formation of antibodies in gout as a result of the reaction of the blood toward uric acid. The

subject is fraught with difficulties, as uric acid is not necessarily present in the blood during a gouty paroxysm, while its occurrence in the urine means nothing at all. But when uric acid is injected into the circulation or peritoneal cavity of rabbits anti-substances are clearly formed. The administration of HCl in man is believed to set free uric acid from its basis and to facilitate its elimination. In a state of perfect health the normal HCl of the gastric juice suffices for this elimination. In discussion, Kraus asserted that gouty attacks were in some way bound up with uric acid formation or retention. There was an entire series of objections to the claim that uric acid formed antibodies, yet such a view would do much toward explaining a gouty attack. We know that in gout the purin metabolism is retarded. Falkenstein replied that if HCl were administered there was no slowing of purin metabolism, and that under these circumstances meat could be freely eaten without prejudice. We are hereby reminded of the cures of gout wrought by mineral acids in cases where alkalies had failed. Falkenstein apparently believes that both diagnosis and treatment by means of sera will yet be available in gout.

The Death of Kroenlein.

It cannot have escaped the attention of the many that a very large number of eminent medical men on the Continent die in their fifties and sixties, although there is no apparent reason why they should not live beyond the three score and ten limit. We know that they are, and must necessarily be, tremendous workers, and often die with arteriosclerosis, but there must be some other factor at work—some factor connected with their professional activities. In the *Münchener medizinische Wochenschrift* for March 21, Luening discusses with much insight the seemingly precocious death of Kroenlein at 63 years; the same reasoning would hold good for many a man who has worked his way to the top in German medicine. In other words, success is bought at such a price that ten or fifteen years of life are sacrificed. Is this shortage due to work or worry? Von Langenbeck used to say that "every surgeon dies of a broken heart." The fearful activity entailed upon an ambitious medical man is given due attention, but it has been shown over and over that overwork *per se* does not kill. But this does not include the psychic traumas. There is much worry to be considered, which involves sleepless nights. Competition of all kinds is at work, as well as living up to one's supposed income. And even more than these causes of worry, for the earnest and conscientious surgeon, is the anxious determining upon and planning of an operation and the plaguing speculation, if it happens to go wrong, whether a different result might not somehow have been obtained. The vacation so well earned is not forthcoming. Luening lays considerable stress on septic infection, which overtakes all surgeons sooner or later. A seemingly trivial affection of this kind, he says, is undoubtedly able to set up an arteriosclerosis. Cloetta, a friend of Kroenlein's, stated that the latter "became a sick man over night." With us such a predication is very common. A feature in Kroenlein's demise, which may throw light on the deaths of other men of his age, is this: He was possessed or obsessed by fixed ideals, and would not mould his life independently of them. In other words, Kroenlein "died a victim of his own disposition."

News of the Week.

The Canal Zone.—During the month of February, 1911, the total number of deaths from all causes among employees was 41, giving an annual average per thousand of 9.88. This is somewhat larger than the rate for the two previous Februaries, as shown by the following table:

1905	14.05
1906	29.09
1907	30.74
1908	12.80
1909	9.42
1910	8.75

The annual average death per thousand for the month of February in the cities of Panama, Colon, and the Canal Zone, including both employees and civil population, was 18.60, which also was slightly higher than for the two previous years, the rate in February, 1910, having been 17.50. Classifying according to race, the annual average death rate per thousand from disease among employees was, for whites 5.67 and for blacks 6.47, a general average for disease of 6.27. For the same month of 1909, the rate among whites was 6.85, and among blacks 6.97, a general average of 6.93; and in 1910, among whites 5.20, among blacks 4.59, a general average from disease of 4.73. The principal causes of death during the month were as follows: Chronic nephritis, 4; hemoglubinuric fever, 1; organic disease of the heart, 3; lobar pneumonia, 3; tuberculosis, 3; and dysentery, 2; leaving 10 deaths from all other diseases and 15 deaths from external violence. An epidemic of measles in mild form existed in the isthmus during the month. No cases of yellow fever, smallpox, or plague originated on or were brought to the isthmus during that time. The general sanitation work has been carried on as usual, and the drying up of some of the anopheles-producing areas has been of great assistance in the antimalarial work.

Public Mealth and Marine-Hospital Service.—An examination of candidates for admission to the grade of assistant surgeon in the Public Health and Marine-Hospital Service will be held in Washington on Monday, May 22, 1911. Candidates must be between twenty and thirty years of age, and graduates of a reputable medical college, and must furnish testimonials as to their professional and moral character. After four years service assistant surgeons are eligible for examination for promotion to the grade of passed assistant surgeon. In the first-named grade the pay is $1,600 a year; in the second, $2,000; while surgeons receive $2,500. Further information may be obtained from the Surgeon-General, Public Health and Marine-Hospital Service, Washington, D. C.

New Operating Rooms.—On April 8 the German Hospital, New York, opened for the inspection of its guests, the new pavilion for thoracic surgery which has been constructed and equipped under the direction of Dr. Willy Meyer. Two steel vaults in the operating room make it possible to perform operations on the thorax either in a partial vacuum or under greatly increased air pressure—negative and positive pressures. The new wing also includes rooms for patients, nurses, and doctors, and an auxiliary room containing duplicates on a smaller scale of the large pressure vaults, to be used for operations involving dangerous infections which it is not desired to attempt in the main operating chambers. The value of experimental

surgery on animals is well shown in the results obtained by Dr. Meyer.

Decayed Food Seized.—The Board of Health inspectors detailed to the examination of food supplies were active last week, and for one day, April 5, the following foodstuffs were reported condemned: Fruit, 186 pounds; vegetables, 191 pounds; fish, 145 pounds; beef, 2,900 pounds; veal, 300 pounds; assorted meats, 525 pounds; poultry, 370 pounds—a total of 4,617 pounds.

To Study Plague Area.—A scientific expedition comprised chiefly of members of the Pasteur Institute of Paris, headed by Prof. Elie Metchnikoff, will start next month for Asiatic Russia for the purpose of studying the epidemic of plague, and also of determining the causes of decrease of vitality among the Kalmucks, a branch of the Mongolian family which is gradually being extinguished.

Another Test Case.—The New York County Medical Society has obtained the arrest of another Christian Science "healer" on the charge of practising medicine without a license. The society is anxious to obtain a decision from the Court of Appeals on that part of the law regulating the practice of medicine which excepts the practice of religious tenets of any church. Such a decision would determine whether or not any "healers" under the guise of religious practices could conduct the business of healing for money and compensation irrespective of regulation by the State authorities. The society thought that it had such a test case recently, when a "healer" was held for trial in Special Sessions, charged with the same offence, but in this case, at the request of counsel, the case was removed to General Sessions, which involves a trial by jury and a long delay because of the congested calendar.

Tuberculosis Boat Camps.—Commissioner Lederle of New York has presented to the Board of Aldermen a resolution passed by the Board of Health regulating the issuance of special revenue bonds in the sum of $10,000, for the purchase of food supplies for patients on board the two day camps for tuberculosis maintained by the department on ferryboats. The food for these patients has heretofore been provided by the Woman's Auxiliary of the Tuberculosis Clinics and the Brooklyn Bureau of Charities, one boat being connected with Manhattan and one with Brooklyn. As the department, however, has complete control over the admission and treatment of patients, and over the employees, it is felt that the city should bear all the expense.

To Study Mountain Sickness.—In camp on Pike's Peak, Colorado, this summer, Prof. Gandell Henderson of the Yale Medical School and Dr. J. S. Haldaere and Dr. C. Gordon Douglas of Oxford University, will make the most extensive investigations ever conducted in this country on the effects on men and animals of high altitudes.

Checking Tuberculosis.—A recent report from the New York State Department of Health shows that there has been a decided decrease in the number of deaths from tuberculosis in proportion to the population. In 1885, for instance, there were in New York City 7,189 deaths from the disease, and in the entire State 11,235, while in 1910 the total for New York City was 8,960 and for the State 14,047. Thus, although there has been an absolute increase in number, this increase has not been proportionate to the increase in population during the same time. During the month of February, 1911, there were 1,245 deaths from tuberculosis in the State, out of a total of 12,548 from all causes.

The Illinois State Board of Health, which is also the State medical examining and licensing organization, issues monthly bulletins dealing not only with the health interests of the State, but also with matters pertaining to medical license laws. We recently published from this bulletin a comprehensive summary of all the State medical practice laws, compiled by the secretary of the Illinois Board, Dr. J. A. Egan. The bulletin for March contains all the bills deemed of particular interest to the medical profession of Illinois that have been introduced into the present Legislature, and shows their status up to the date of publication. Such a publication, it is needless to say, is of inestimable value to the medical profession of the State, acquainting them with the measures in their interest as well as with those inimical to the unity of medical practice. One of the latter, a bill admitting osteopathic practitioners to practise the healing art without qualifying as doctors of medicine, has been defeated through the efforts of the State Board of Health and of the medical practitioners of the State. Another, giving optometrists the right to practise without a medical education, is still before the Legislature, but will, it is hoped, meet the fate of the osteopathic bill. It stands to reason that all men who profess to treat human ills should prove themselves qualified to do so according to the same standards. The Illinois Board of Health is doing a commendable work in keeping the physicians of the State informed of proposed legislation affecting their interests, and the medical licensing bodies in other States might well follow this excellent example.

A Doctor Honored.—Wauconda, Illinois, a village about thirty-five miles north of Chicago, is preparing to honor the memory of Dr. W. C. Dawson, the village physician, who died there a year ago. A monument costing about five hundred dollars is to be erected to bear public testimony of his fellow townsmen's appreciation of his services. Dr. Dawson's death followed a general breakdown attributed to too close attention to his work.

Civil Service Examinations.—The New York State Civil Service Commission will hold an examination on April 20, 1911, for the purpose of filling a vacancy in the position of assistant superintendent of nurses, Department of Health Officer (Quarantine), New York, at a salary of $720. At the same time examinations will be held for eligibles to fill vacancies in the ranks of physicians, as these occur, both regular and homeopathic. Full particulars can be obtained from the State Civil Service Commission, Albany, New York.

Typhoid Epidemic.—Iselin, Pennsylvania, has had an epidemic of typhoid fever, the infection being attributed to contamination of the water supply.

Fire in a Hospital.—The Philadelphia Hospital at Thirty-fourth and Spruce streets, Philadelphia, was badly damaged on April 6 by a fire which, breaking out in the laundry building, for a time threatened the entire institution. The damage is estimated at $285,000. Two hundred patients in the tuberculosis pavilion were carried out through the dense smoke, and the doctors and nurses had a strenuous time quieting the panic among the patients in the general wards of the hospital and in the insane and blind departments close by, all of

whom were almost unmanageable from fear. That the loss was entirely a monetary one is due to the coolness and bravery of the hospital staff and attendants.

Hospital Staff Quits.—The entire house staff of St. John's Hospital, Long Island City, New York, consisting of six internes, left the institution on April 5 under charges of insubordination. The internes complained that they did not have complete medical and surgical control over the patients, and tendered their resignations unless assured of certain concessions. The medical board of the hospital refused to make these concessions or to accept the resignations, and finally dismissed the entire staff.

The Ewald Injunction.—The Apellate Division of the Supreme Court of New York on April 7 reversed the judgment of the Special Term granting to Dr. Louis A. Ewald an injunction restraining the Medical Society of the County of New York from trying him on charges. The Court holds that while Dr. Ewald can not be tried after restoration to membership on charges on which he was suspended, the society can try him on other charges which have been brought against him.

More Meningitis from Greece.—On the steamship *Germania*, which arrived in New York on April 2 from Mediterranean ports, were two steerage passengers ill with spinal meningitis. Two other passengers were reported as having died during the voyage, probably from the same disease. All of the steerage passengers on the ship were Greeks. The Greek Line steamship *Themistocles*, which arrived in New York on the following day, also reported the deaths at sea of two steerage passengers with symptoms of meningitis. The federal government has made arrangements by which all steerage passengers from Greek ports will be detained for observation for ten days before being permitted to embark for American ports.

Diphtheria Epidemic.—Because of an epidemic of diphtheria, all the schools in Hellam Borough, Pennsylvania, were ordered closed recently by the State Health Commissioner, and on Sunday, April 1, no services were held in the churches. Forty cases had occurred up to that time.

City Death Rate.—For the week ending April 1 the death rate in New York City was 19.19, as against 18.16 for the same week of 1910. This increase, however, was entirely due to the loss of life in the Washington place fire, which brought the total number of deaths due to violence up to 206 for the week, as compared with 98 a year ago. Had it not been for these 145 deaths, the rate in New York would have been 17.67, less than the preceding year.

Orange's Rate of Growth.—During the year 1910 there were 834 births in Orange, New Jersey, including four pairs of triplets and one set of twins. There were 451 deaths and 278 marriages in the same period. The birth rate showed an increase of 9 per cent. over that of the preceding year.

Gifts to Charities.—The New York Eye and Ear Infirmary receives a bequest of $1,500 under the will of the late Mary E. Poillon, with an additional $1,000 to be paid upon the death of another beneficiary.

Obituary Notes.—Dr. James Evelyn Pilcher of Carlisle, Pa., died in Savannah, April 8, at the age of 54 years. He was born in Adrian, Mich. He studied first at the University of Michigan and later at the Long Island College Hospital, and was graduated from the latter institution in 1880. He entered the medical corps of the U. S. Army in 1883, and continued in the service until 1900, when he retired, his health being broken by the strain to which he had been subjected during the Spanish-American war. Upon his retirement from the army his services were sought by Dickinson College, in which he held the Chair of Anatomy and Embryology in 1900, and that of Economics and Sociology in 1901-1903. He also was Professor of Medical Jurisprudence in Dickinson School of Law.

Dr. Charles Talbot Poore of New York, a graduate of the College of Physicians and Surgeons, New York, in 1866, surgeon to St. Mary's Free Hospital, consulting surgeon to the Hospital for the Ruptured and Crippled, and Associate in Surgery in the College of Physicians and Surgeons, and a member of the New York State and County Medical Societies, died suddenly at his home on April 4.

Dr. Joseph T. Miller of Hartford, Ky., a graduate of the Jefferson Medical College, Philadelphia, in 1870, died at his home of pneumonia on March 11, aged 71 years.

Dr. Gustave A. Spreckelmeyer of St. Louis, Mo., a graduate of the Missouri Medical College, St. Louis, in 1879, formerly coroner of Gasconade county, Missouri, died at his home after a short illness, on March 21, aged 54 years.

Dr. John B. Stewart of Clarksburg, Mo., a graduate of the Cincinnati College of Medicine and Surgery in 1877, and a member of the Missouri State and Moniteau County Medical Societies, died at his home on March 18, aged 73 years.

Dr. Harrison A. Lyding, an interne at the Michael Reese Hospital, Chicago, Ill., and a graduate of the Rush Medical College, Chicago, in 1910, died at the hospital of scarlet fever on March 20, aged 23 years.

Dr. Charles Louser Miller of Lebanon, Pa., a graduate of the Medical Department of the University of Pennsylvania in 1889, and a member of the State and County Medical Societies, died at his home after a long illness, on March 25, aged 56 years.

Dr. Adolph G. Hoen of Richmond, Va., a graduate of the University of Maryland School of Medicine, Baltimore, in 1877, a member of the Virginia State and Henrico County Medical Societies, director of the Pasteur Institute of Virginia, died in Baltimore on March 29.

Dr. Christopher C. Oliver of Calera, Ala., surgeon-general of the Fourth Brigade, Alabama Confederate Veterans, a graduate of the Atlanta Medical College in 1869, and a member of the Alabama State and Shelby County Medical Societies, died at his home on March 22.

Dr. William Edward Hibbard of Pasadena, Cal., a graduate of the Medical Department of New York University in 1889, formerly surgeon to the Roger Williams Eye, Ear, and Throat Infirmary in Providence, R. I., a Fellow of the New York Academy of Medicine, the American Academy of Ophthalmology, the American Medical Association, the New York State and County Medical Societies, and the California State and Los Angeles County Medical Societies, died at his home on March 17, as the result of severe burns, accidentally received.

Dr. Edward W. Aiken of Perry, Iowa, a graduate of the Albany Medical College in 1868, died in Spencer, Neb., on March 18.

In Memoriam.

EDWARD GAMALIEL JANEWAY, M.D.

On Thursday evening, April 6, the members of the New York Academy of Medicine met to honor the memory of Dr. Edward G. Janeway and to listen to addresses reminiscent of his character and work. Dr. Janeway was orator of the Academy of Medicine in 1895, president for the year 1897-1898, and a trustee from 1899 to 1903.

Dr. Polk, president of the Academy of Medicine, in his opening remarks said that he considered it a great privilege to ask the audience to listen to addresses concerning one who had held such a high place in the profession. Many letters had been received from those who were unable to be present, expressing esteem for Dr. Janeway and regrets that their writers could not testify by their presence to Dr. Janeway's power as an inspiration to the young and as a cherished memory to his contemporaries. Among the writers of these letters were Drs. James J. Putnam and J. C. Wilson, and Dr. Charles F. Chandler who was to have made an address recalling Dr. Janeway's work as a sanitarian.

Dr. Francis Delafield, who spoke of Dr. Janeway as a "Physician," said that in 1888, in a memorial address on Dr. Alonzo Clark, he had referred to him as his father in medicine, and he now called Dr. Janeway his brother in medicine. They had done the same work in college, and side by side the same work in old-fashioned family practice; later they had worked into larger spheres of usefulness. In all lines of work there were many competent men, but few great ones. Dr. Janeway was a great physician. To become great required natural endowment, opportunity, and industry. Natural endowment included the physique, memory, and judgment. Of all of these Dr. Janeway had more than sufficient. The opportunity meant seeing many sick people and a large variety of diseases. To see only a few sick people or only one class of diseases narrowed the mind. Industry to be effective must be combined with enthusiasm. This Dr. Janeway possessed. It meant to him untiring study of the human being in health, in disease, and after death; it meant much laboratory work, and with it all there remained the feeling of ignorance and of humility. Dr. Janeway was unerring in diagnosis and seldom revealed the full extent of his knowledge.

Dr. William H. Welch of Johns Hopkins University paid tribute to Dr. Janeway as a "Pathologist." He said that when Dr. Janeway was president of the Association of American Physicians he took as the theme of his address "Truth; Truth in Diagnosis, Truth in Therapeutics, and Truth in Pathology." If there ever was a seeker after truth Dr. Janeway was one, and this was the keynote of his character. He sought truth by hard work, and he had the joy that comes to the seeker after truth. His success as a physician and consultant was due to the early years spent in hospital wards, combined with the study of morbid anatomy. Dr. Janeway began work in the deadhouse at Bellevue in 1866 and was one of the first curators of Bellevue Hospital, together with Delafield and Southern. These men instituted the system of keeping records which until this time had been done in a very imperfect way. Dr. Janeway was a teacher from 1872 onward. His first public contribution appeared in 1868, when he presented a specimen to the New York Pathological Society. He entered the study of pathology at an interesting period in the evolution of that science, and for ten or twelve years did the hardest kind of work, combining clinical study in the wards of the hospital with the study of appearances presented post mortem. He read extensively the writings of French and German investigators and was familiar with the use of the microscope. However, he was essentially an original worker, a keen observer, and an excellent interpreter. His methods were those used in the laboratories of Europe, though he followed no method slavishly. Dr. Welch stated that he had never met anyone who went more thoroughly to the root of a matter than Dr. Janeway. He showed almost superhuman detective power in ferreting out the hidden causes of disease, combined with wonderful zeal and enthusiasm for his work. When there was a discussion as to the diagnosis in any case Dr. Janeway's was usually the correct one. Dr. Welch expressed himself as having received great inspiration from Dr. Janeway's work and as being desirous of paying special tribute to him for the stimulus that association with so great a man had given him. It had often been stated that the results of Dr. Janeway's pathological work were meagre and that he had contributed but little to the literature. This was a mistake. In a search which was by no means complete he had found sixty-six contributions to the literature, covering a large range of subjects, and fifty published records of interesting cases and specimens. This might not be the time to discuss the value of these, but he would say that they had been used far too little. After all, results were not to be measured by published contributions, but by the influence of one's work on himself and his pupils. Janewey's work had made him a leader among physicians, an acute diagnostician, and had won for him the confidence of the profession, and it was upon the basis of this confidence that he became a great consultant. His diagnoses were not intuitive, as some claimed, but were due to his rare qualities of mind and to his very tenacious memory, a memory that stored up every experience, so that when he made a diagnosis that seemed difficult he would say he knew he was right because he had seen a case just like this one. Dr. Welch said that in the capacity of health officer and sanitarian no one had ever been less self-seeking. He had served the city well by introducing important reforms. He did the very best possible with the knowledge the time afforded, and this work should not be forgotten. The value of Dr. Janeway's work as a pathologist, a great teacher, a leader, and a great diagnostician, should be commemorated by some fitting memorial. He represented the best type of physician and the highest ideals of manhood, and his name should be held in grateful remembrance throughout the history of medicine in this country.

Dr. Abraham Jacobi recalled his association with Dr. Janeway as a "Consultant." They had been thrown together in the work of Mount Sinai Hospital since 1883. He felt that as a medical brother Dr. Janeway's honor was theirs, his life a gift to them. His chaste and scientific life, his concern for the welfare of the community at large, both the indigent and the affluent alike, made a book instructive to all. Dr. Jacobi considered particularly Janeway's work as a teacher and his appreciation of the part that the hospital played in

the preparation of the young physician. In his task of teacher to class and staff he never exhibited any consciousness of his superior personality. It was a great misfortune to the profession that his work had been so onerous that he had been unable to appear oftener before them. Dr. Jacobi called particular attention to his address entitled "On the Borderline of Medicine and Surgery." His like was rare. He was both broader and more profound than most men. He spent himself unselfishly for others. He was impregnated, the speaker said, with the wisdom of Descartes, according to whom, "If it is possible to ennoble men it will be through medicine." One of his loveliest qualities was that he looked always for results and not for renown. Edward Gamaliel Janeway was good, great, modest, and not to have known him was indeed a loss.

Dr. Joseph D. Bryant, who had worked as demonstrator of anatomy for three years under Dr. Janeway, had served on the faculty of Bellevue Hospital Medical College with him, and on the visiting staff to Bellevue Hospital, spoke on Janeway as "Colleague and Friend." There had never been the shadow of a disagreement between them because Dr. Janeway's clear insight and deliberate attention to all matters brought conclusions that could not be gainsaid. He had not been born to command, but he exercised great power through the respect that he inspired. Neither was he a disciplinarian in the compelling sense of the term. He ruled rather by his example and his strong sense of right. He never fostered a memory of wrong, whether of principle or of action. Physicians in conversation among themselves sometimes disregarded professional secrets; the ethical secret always rested safely in his keeping. The devious methods of business reciprocity which had taken hold of some members of the profession were no portion of his belongings. He gave abundantly to charity both of his time and his means. Withal he was thoroughly human and enjoyed humor, and on social occasions contributed his part, but always with modest dignity and fitting propriety. Dr. Janeway was a repository of medical knowledge equaled by few and surpassed by none. He aroused an abiding sense of confidence in all with whom he came in contact. His resignation from the faculty of Bellevue College in 1907 was received with great regret, as the resolutions presented to him at that time demonstrated. Dr. Bryant also spoke of the work that Dr. Janeway had done for the city when he also had been a part of the Health Department. Later, when Dr. Bryant became Health Commissioner, the experience and wisdom of Dr. Janeway had served to lighten the responsibility of official care. Even the building in which this meeting was held had been aided by his sound advice and generous contributions. Dr. Bryant related that the last interview which he had had with Dr. Janeway had been last summer in connection with the purchase of additional property for the academy. Dr. Janeway had approved of their present location and of their plans for future requirements, his only fear being that financial difficulties might arise. It was certainly fitting that his professional attainments and ideal manhood should be made evident in this building. Dr. Janeway as both a personal and a professional friend had never failed to come to his support, and he had always bestowed his willing services so as to make of labor a cheerful duty.

Correspondence.

THE BAYNE ANTIVIVISECTION BILL.

To the Editor of the Medical Record:

Sir:—Two bills have been introduced in both the Senate and Assembly of this State, one of which has been reported out of committee, touching the subject of antivivisection. One of these, the Bayne bill, is empowered by its title to "create a commission to inquire into the extent and nature of the practice of experimentation on living animals and the condition of the laws of the State relative to the proper protection of scientific experiments without danger of unnecessary cruelty." The bill provides that the Governor shall "appoint a commission consisting of seven members, two of whom shall be scientific men residing in this State, two of whom shall be active members of some organization of this State, having for its purpose the prevention of unnecessary cruelty in vivisection, two of whom shall be lawyers practising within this State, and the remaining member of this commission shall be appointed at large." I think this ought to be amended so as to give the scientific men three members of the seven instead of two. It then goes on to say that "such commission shall make inquiry, examination, and investigation into the practice of vivisection or experimentation on living animals. It shall also make a full inquiry and investigation into the condition of the law of this State for the protection of scientific investigation of this character in this State, as well as the condition and effectiveness thereof for the prevention of abuse in vivisection and of unnecessary cruelty to animals therein. For these purposes the said commission is hereby authorized to send for persons or papers, to administer oaths, and to examine witnesses and papers respecting all matters pertaining to this subject. Such commission shall make a full and final report to the Governor within one year after its appointment, including such recommendations for legislation as in its judgment may seem proper." This commission is to serve without compensation and no appropriation is asked for; the expense of said commission of whatever character shall be met by voluntary contributions.

With all due respect to my professional brethren, I think they would be foolish if they oppose this measure. Note, no authority is given to this commission to enter any laboratories for the purpose of investigation or to obtain information. It is only authorized to "make a full inquiry and investigation into the condition of the law of this State for the protection of scientific investigation of this character in this State," etc. Medical men will be wise if they meet this commission half way, lest a worse fate befall them, for another bill has been introduced into the Senate by Mr. Pollock, which is drastic and inquisitorial in its character. A reputable portion of the community is violently opposed to all animal experimentation in this State, and it has been roused to this antagonistic attitude by the erroneous and exaggerated statements made by the advocates of antivivisection and by the exhibits which from time to time have been publicly made of what is supposed to take place in laboratories. I hold no brief for the antivivisectionists, as you perhaps know, but I feel that the stubborn attitude of the medical

profession in opposing any investigation or inquiry is sure to arouse increased antagonism, for the public will be inclined to say: there must be something radically bad in animal experimentation, else why should the doctors refuse to have any inquiry made as to what is done? Depend upon it, if the public is determined to know what takes place in laboratories for animal experimentation it will sooner or later find out, and the medical profession only injures itself by saying to the public: you shall know nothing; it is none of your business. In this connection I would ask the doctors to remember what happened when some years ago the licensing all physicians to practise by the State was opposed by the medical colleges and their followers.

F. R. Sturgis, M.D.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

DEBATE ON COLITIS.—SIR A. WRIGHT'S UNORTHODOX HYGIENE.—HOSPITAL MANAGEMENT AND SCHOOL CLINICS.—QUALIFIED OPTICIANS.—MEASLES AT NAVAL COLLEGE, AND GOVERNMENT SECRECY.—OBITUARY.

London, March 24, 1911.

The Harveian Society's set debate on colitis came off on the 9th inst. Dr. Sidney Phillips began by saying that cases were sometimes classed as membranous which were really inflammatory, while others were called colitis in which there was no inflammation. Post-mortem examination confirmed this view. He thought no strict line could be defined between simple and ulcerative acute colitis. Sometimes ulceration was deep and extensive enough to destroy a large area of the wall of the colon. Perforation was not uncommon; the colon might be riddled with holes, and in one case desiccated fecal matter was found in the abdominal cavity, showing that death had been deferred for days after perforation. Acute paroxysms of abdominal pain, which did not occur in typhoid fever and leucocytosis also occurred in colitis, but not in typhoid. Hiccough was a frequent symptom. There was evidence that acute colitis might be caused by articles of food, and he mentioned some cases to show this. The worst cases might recover. Opening the intestine or appendix had saved some lives, but had not resulted in the immediate cure that had been expected.

Mr. D'Arcy Power followed. He said thorough examination must be made for diagnosis, the bowel being washed out and explored by finger and sigmoidoscope. Gross causes were scybala in the sacculi, polypi, cancer, and same bacterial infections. Apart from these chronic ulceration might occur with extensive destruction, leading to toxemia. In late stages the disease was easy to diagnose, but early the patients did not look as ill as they were. He advised mild treatment at first, but after a while vaccine therapy, or, if necessary, appendicostomy. This operation did not cure, but it enabled the bowel to be kept clean, and prevented absorption of toxic products. Thus it led to improvement in advanced cases, but temporary relapses were apt to occur. For irrigation many drugs were too irritating. He preferred subcarbonate and potassium permanganate; later bichloride of mercury, zinc sulphate, or silver nitrate. As an anodyne he found chlorodyne useful.

Dr. Hale White thought constipation the chief cause of membranous cases, and the majority of women were better when that was removed. Ulcerative colitis might be secondary to disease of the appendix, in which case its removal would do good, but not if the appendix was merely involved in the general state of the bowel. Secondary colitis should be distinguished; it might be due to irritation, extension from other parts, pyemia, Bright's disease, pneumonia, injury, or, most important of all, malignant disease. In secondary cases the outlook was very grave, but in primary cases much good could be done. The essential thing was to keep the bowel clean—castor oil or irrigation would do this. If they failed appendicostomy allowed washing with saline solution. This was not often necessary in membranous, but was in ulcerative cases. After operation vaccine treatment helped.

Mr. Bidwell would not advise recourse to surgery until medical measures had failed. He confirmed some of the previous speaker's statements, as in several cases when he intended appendicostomy he found the appendix so thickened and inflamed that he thought perhaps secretion from it caused or kept up the colitis. He therefore removed the appendix, thus curing the colitis. But in two cases it did not cure. He had met cases of another type, a single ulcer involving the coats of the bowel deeper and leading to adhesions, kinking, obstructions, perforation, abscess. Of such he related two examples. In one of them no abscess had formed, and he did ileosigmoidoscopy fourteen years ago, the patient being now alive and well. This operation is only available when the lower half of the sigmoid is healthy, and this can only be ascertained by the sigmoidoscope, which with care can be used without danger even if inflammation of the sigmoid be present.

Dr. J. C. Matthews spoke as a surgeon to whom cases were usually referred only for identification of the organism. These were numerous in colitis, and in most cases—in all of the mucous variety—the pathogenic microbe could only be decided by inference. Sometimes a direct method might obtain it, *e. g.* a swab through the sigmoidoscope. He mentioned the case of a cook who seemed to be dying in St. Mary's Hospital, but a vaccine was prepared from her own organism in a few hours, and she recovered under the use of it. She returned to her work, but for some months came as an outpatient for another dose, as without it attacks of diarrhea and colic occurred. A number of other cases were reported in groups. Of his own cases he said he had had sixteen, and in only three was there no improvement, ten recovered completely, and three were much improved. In one of the intractable cases he had tred four different vaccines, and was about to try a fifth; in another three were tried without effect; in the third, only one was tried.

Dr. Buckley described the treatment adopted at spas by irrigation with mineral waters.

The National Health Society enjoyed the mild excitement of a slight shock in the second lecture in memory of Lady Priestley. It was given, as I told you last week it was to be, by Sir Almroth Wright, who rather likes to express unorthodox views, and took this opportunity of contradicting a number of notions which the society has been propagating. He was on the Plague Commission in India, and recommended sterilization of floors, but now he told the audience it cost a lot and did no good, for the fleas came hopping along whether the floors were disinfected or not. He felt the wisdom of the man who said if any member was in favor

of doing nothing he took his side. There was much talk of catching rats, but he didn't know if that was any use. He didn't know if measles was infective in the early stage; its epidemics were as bad as sixty years ago. It was a widespread belief that if you had not got a disease you could keep it away by following certain rules, and if you had it you could make it better by them. That religion he had no sympathy with. People said you must have hard exercise, much washing, and fresh air—all wrong. He would not say these things did not conduce to the amenities of life, but there was no evidence that they lessened the liability to disease. It was thought that they might wash off microbes, and they did some, but did harm as well. Better be dirty than infected. No microbes could get through a horny skin. In a Turkish bath they got stewed and then had the outer protection rubbed off. Nobody had more microbes than one coming out of the Turkish bath. The religion of fresh air had all sorts of dangerous sides. The fresh air treatment of consumption was a dreadful superstition. At the London Hospital, not long ago, some men went into a glass cage. The air became hot and the men sleepy. Then the doctor, by a turbine arrangement, stirred up the vitiated air without admitting a bubble of fresh, and the men became lively again. It was awkward to be in a crowded room, but deplorable that on this a whole theory should be built, and large sums spent in accordance with it. He did not feel that we had reached valuable knowledge about public, domestic, or private hygiene. If we never used what we had we should not be much the worse. Epidemics were only incidents, and did not matter much; the permanent disabilities were local infections. Few people understood that noninfective diseases were microbic. Hygiene was a question of fighting microbes. It was said that prevention was better than cure; he did not believe it. As Kruger said, wait till the tortoise puts out its head, then kill it. The program had been to kill the microbe outside the body—a difficult thing to do. His policy would be to kill it inside, which could be done if they took the trouble to study it. The body had protective and destructive substances which could be enlisted in the fight. But more research was required. It was no good filling hospitals with people unless they knew how to treat them. He had seen twenty-one doctors round a rich man's bed, and not one of them knew anything about him.

The lecture cannot be pronounced a success, and has elicited some rather sharp expressions of disapproval. Even the chairman on the occasion (Lord Justice Moulton) felt obliged to differ, and suggested that perhaps the object of the lecturer was to arrest the attention of the audience. Others are less lenient, and think that "parodoxes," or "whimsicalities," suggested excesses were, at the least, inappropriate. So is the view that Sir A. Wright wanted to pooh-pooh the activity of a popular appeal for the promotion of hygiene. Even so he might have remembered that these lectures were established to commemorate the work of the late Lady Priestley, who spared neither toil nor expense to promote national health, as understood by the society which invited him to lecture.

At the annual meeting of Poplar Hospital for Accidents, the Hon. Sydney Holland, presiding, referred to the treatment of school children for the County Council, and maintained the voluntary hospitals could do the work just as well and at far less cost than new clinics, which meant new buildings, new machinery, and more extravagance. He thought, too, the hospitals should be helped by the State, as they are in other countries. If England did as much for hospitals as Australia it would be a great assistance, and they would willingly admit a State representative on their committees to see that the money was properly spent. But he would be sorry to see municipal control of hospitals. Because a man went through an election as a popular tradesman that was no evidence that he knew anything about hospital administration.

In poor law management there was often one thing missing, and that was the big heart. The whole spirit of the poor law was to do as little as possible for people in distress. The spirit of hospitals was "We do all we can for you."

I have already reported that the Education Board had been requested to sanction a further arrangement with hospitals by those local authorities who were trying the plan instead of school clinics. This week a further conditional trial has been authorized up to Christmas.

In February I wrote to you that Dr. Seymour Taylor, dining with the Spectacle Makers' Company, had spoken in favor of the certificate issued by the company purporting to be a qualification to examine for refraction, etc. As I expected, he has found himself in hot water with some who naturally enough condemn the handing over to tradesmen any branch of the profession. He has defended himself as well as he could with various platitudes about the people's liberty to go where they please for advice, and that in this case it is cheap advice. In his vexation he has cast a slur on general practitioners as mostly knowing nothing about eyes. Therein he greatly errs, and lays himself open to the *tu quoque*. But that argument is mild compared to the epithets applied to the physician who owes his own prosperity to these G. P.s who are as competent to call in the ophthalmic surgeon when required as the medical or other consultant. They are equally prepared to join in a consultation and to carry out any line of treatment required. Not so the tradesmen that Dr. Taylor exalts as competitors for the less important cases.

The epidemic of measles at the Naval College at Osborne has been the occasion of much foolish talk and some anxiety, aggravated by the ridiculous way in which this government attempts to keep the most obvious things secret. The first Lord of the Admiralty has been compelled by cross examination in parliament to make a statement. He said one hundred and fifteen cadets in the college had had measles, two hundred and fifty-eight German measles, and sixty conjunctivitis, "popularly miscalled pinkeye." He added that in the opinion of the Admiralty the medical staff were quite able to cope with the matter. How can there be any danger to the State in this revelation? But secrecy seems a part of the government's existence, and on occasion is maintained by misstatements (the parliamentary word for falsehood). Witness the educational minister repeatedly denying the existence of a circular until confronted by a copy—read by a member to the House.

Dr. Leonard W. Sedgwick died suddenly on the 21st inst., at the age of eighty-two. He held a good position until his retirement, several years ago, with the respect of all his contemporaries. He first qualified in 1850. He took the M.D. St. Andrew's, in 1859. He had been president of the Medical Society of London, and occupied other hon-

orable posts. He was joint author of the New Sydenham Society "Lexicon of Medicine." He contributed to St. Thomas' Hospital reports and the weekly medical journals.

Prof. John Attfield, F.R.S., died on the 18th inst., aged seventy-five. He was for thirty years professor of practical chemistry to the Pharmaceutical Society. From 1854 to 1862 he taught chemistry at St. Bartholomew's Hospital. His manual of pharmaceutical chemistry has had a long, authoritative position. He contributed many excellent papers to the "Transactions," etc.

OUR BERLIN LETTER.

(From Our Regular Correspondent.)

MEDICAL PRACTICE IN GERMANY—RADIUM IN RHEUMATISM AND GOUT—CAMPAIGN AGAINST PLURALITY OF PHYSICIANS' OFFICES.

BERLIN, March 7, 1911.

THE Imperial Medical Almanac for the year 1911 presents a review of the conditions of medical practise as they prevailed in Germany during 1910. As in previous years this review has been made by F. Prinzing. The interesting results of his statistical investigation are as follows: The total number of practitioners in 1910 was 32,449, or 5.01 to every 10,000 inhabitants. There was an increase of 480 physicians over the previous year. A larger increase for the coming years is to be expected for there has been a marked increment in the number of medical students. During the summer semester of 1905 there were 6,032 of the latter, while in its corresponding session of 1910 there were 11,125. The large cities have shown the greatest increase in the number of physicians. In Berlin there are 12.32 practitioners to every 10,000 inhabitants. The number of women physicians in Germany has increased from 55 in 1908, to 69 in 1909, and 102 in 1910. Among the specialists the largest quota is represented by the gynecologists; then come in order the ophthalmologists, the otologists, and laryngologists. The cities of Dresden, Leipzig, Frankfort, and Nuremberg have as many specialists as 40 per cent. of their entire number of practitioners.

After many futile attempts radium has at last demonstrated its value in internal medicine. Unfortunately, of the three methods of employment of radium, the radium drink cures, the injection of radium salts, and the inhalation of radium emanations, the last method has been found to be the most successful. Since this necessitates the use of expensive apparatus, it is not generally available for the use of the practitioner. W. His has recently reported before the Berlin Medical Society his success in the treatment of gout, and rheumatism by means of this remedy. He treated 100 cases of chronic rheumatism, of which 5 were entirely cured, and the majority of the remainder were greatly improved. The pains subsided, the contractures diminished, and the general condition was improved to an extraordinary degree. Of 28 cases of genuine gout, 24 were improved. In a few weeks the blood lost its uric acid excess, although the pains did not diminish to a like degree. In two cases the tophi on the lobule of the ear disappeared. It was concluded that radium inhibited the inflammatory wanderings of the leucocytes and the ferments were aroused to activity. The earlier the cases come under treatment, the quicker and more marked is the cure. In the beginning of the treatment the symptoms are aggravated. The dose of the emanations must be adjusted to the individual case. Many cases of myalgia, sciatica, and neuralgia, which are occasionally manifestations of gout, are benefited by the radium treatment.

A warm discussion has recently been going on in Berlin medical circles relative to the practice among certain physicians of having two or more offices. This practice has for a long time been opposed in the society meetings and in the society publications without any definite result. In order to sound the sentiment of the profession regarding this matter, the Society for the Prevention of Abuses in the Policlinics has sent out a questionaire to Berlin practitioners and has received answers from 1,380 of the latter. Of these there are 713 engaged in general practise, 491 in specialties, and 176 are engaged in general and in special practice at the same time. Utterly opposed to the maintenance of two offices were 47 per cent. of the general practitioners, 20 per cent. of the specialists, and 42 per cent. of those belonging to both groups. About 30 per cent. of all three groups consider it proper for a physician to maintain one office for his private patients, while another may be maintained for a so-called "cash" practice. Four per cent. of the entire number believe that there should be no restriction as to the number of offices where a physician may desire to follow his calling. These figures certainly indicate no unanimity of opinion. Although the practice of having many offices is generally condemned, there is no prospect of any action being taken against the offending physicians.

EIGHTH ANNUAL MEETING OF THE PHILIPPINE ISLANDS MEDICAL ASSOCIATION.

(From Our Regular Correspondent.)

MANILA, February 23, 1911.

THE eighth annual meeting of the Philippine Islands Medical Association began its sessions in the amphitheater of the College of Medicine and Surgery of the University of the Philippines on February 22, 1911. The official opening was preceded by a surgical clinic given at the Philippine General Hospital by Dr. John R. McDill, chief of the department of surgery of that institution. It was decided this year to limit the sessions entirely to scientific subjects, and for that reason no general invitation was extended to the public for the opening session.

The first paper read was an address entitled "Electricity as a Powerful Therapeutic Agent," by Dr. Benito Valdez, the president of the association.

The next paper, entitled "Spinal Anesthesia," by Dr. D. N. Molloy, gave a series of 102 cases in which scopalamine had been used successfully without a single fatality or untoward symptoms. The author stated that he had made a study of the literature of spinal anesthesia and deduced therefrom that when done by persons who used scopalamine and who were thoroughly familiar with the technique of its administration only one death in approximately 10,000 cases had resulted. He stated that its use was now generally conceded to be the anesthetic of choice in diabetes, and he also recommended it strongly in cases of general peritonitis in which the prognosis was so grave that the shock of a general anesthetic could not be safely risked. In the discussion which followed, Dr. Schiffbauer, the resident surgeon at the Philippine General Hospital, stated that a review of the literature showed that

approximately one death in 700 occurred in the use of spinal anesthesia, whereas only one death in 8,000 occurred in chloroform and one death in 10,000 in ether anesthesia. From this he thought it was beyond dispute that ether must for the present, at least, remain the anesthetic of choice in the great majority of cases.

The next paper, by Dr. Henry Schmid, was entitled "A Study of Five Hundred Cases of Peritonitis." This paper gave the results of the author's observations in the hospitals of Berlin, and he presented a statistical table in which he showed that the operative mortality in general peritonitis from 1900 to 1910 had gradually fallen, and this he attributed to the fact that it had become customary in Berlin to depend almost entirely upon drainage, with the minimum amount of manipulation of the intestines. In the discussion which followed, Dr. Schiffbauer stated that in the experience of American surgeons the operative mortality was less than the figures quoted by Dr. Schmid, and this he attributed to the excellent results obtained by Murphy and his followers by using the continuous rectal irrigations of salt solution.

The next paper, entitled "The Treatment of Burns," by Dr. H. Schiffbauer, dealt principally with the history of the seventy-eight victims of the recent Taal Volcano disaster that had been treated at the Philippine General Hospital. The author stated that the best local application in his experience was found to be picric acid. He called attention to the fact that deep-seated collections of pus had formed near the bone of the extremities in many of the cases which apparently only had superficial burns.

The next paper, entitled "Infantile Beriberi Treated at the 'Gota de Leche Institution,'" was read by Dr. Fernando Calderon. This paper was illustrated with lantern slides which gave a general idea of the work which is being done by this institution. The author showed that the cases of beriberi brought to the institution almost invariably gave evidence that there had been deficient nutrition, and that unless degenerative changes had actually set in prior to their being presented for treatment the cases soon recovered when they were placed upon properly modified pasteurized milk.

The next session was held the morning of February 23.

The first paper read was entitled "Report of a Case of Hydrophobia Treated at San Lazaro Hospital," by Dr. Almon P. Goff, chief of the San Lazaro Hospital Division of the Bureau of Health. He stated that on December 25, 1910, there was admitted to the dangerous communicable disease ward of the San Lazaro Hospital a woman with a history of having been bitten forty days previously by a dog which was later proved to be afflicted with hydrophobia. The case was especially interesting because it was the first that had ever come to the notice of that institution. It died four days after admission. The diagnosis was confirmed by autopsy and microscopical findings.

The next paper, "Visual Acuity and Rifle Shooting," was read by Major Henry A. Shaw, Medical Corps, U. S. Army. The conclusion reached by the author was that normal vision did not necessarily go hand in hand with the best marksmanship, and that a study of many of the best marksmen of the army showed that many of them were afflicted with refractive errors, which ranged from 0.25 to 0.75 dioptres of astigmatism, myopia or hyeropia, or compound conditions.

The next paper was entitled "Practical Experiences with Unpolished Rice and Beriberi in the Philippines," by Dr. Victor C. Heiser. A brief account was given of the results obtained in the use of unpolished rice in the prophylaxis of beriberi, and cited the experience at the Culion Leper Colony. Since the opening of the Culion Leper Colony in 1906 rice has been the staple article of diet, and it was customary to use either Saigon rice No. 2 or local polished rice. Beriberi was more or less continuously present until February, 1910. By substituting meat and mangoes for rice it was always possible to reduce the number of beriberi cases, but it was never completely eradicated. It was found later that this failure was probably due to the fact that many of the lepers preferred to deny themselves food rather than to eat mangoes, so that we had starvation as well as improper diet to deal with. The total number of deaths at Culion by months from February, 1909, to February, 1910, among an average population of 1,537 was as follows: February, 39; March, 54; April, 52; May, 47; June, 48; July, 57; August, 61; September, 65; October, 43; November, 80; December, 188; January, 164, or a total of 898; of this number 309 were due to beriberi. In February, 1910, the use of unpolished rice was made compulsory for all inmates of the Culion Leper Colony. The total number of deaths by months from February, 1910, to February, 1911, among an average population of 1,952, or a 27 per cent. greater population, was as follows: February, 66; March, 36; April, 29; May, 22; June, 27; July, 15; August, 24; September, 12; October, 13; November, 15; December, 58; January, 52, or a total of 369, *a reduction in the deaths of over one-half. Of this number there were no deaths from beriberi after February*, 1910. The increased death rate in December and January was due to an acute outbreak of bacillary dysentery, or even a better showing would have resulted. At the end of January, 1910, there were approximately 50 cases of beriberi undergoing treatment in the Culion Hospital. Upon the suggestion of Dr. Aron 15 grams of rice polishings mixed with milk and sugar was given to these patients twice daily. With the exception of two very advanced cases that died within a few days after this treatment was begun, all the remaining cases began to improve. Within two weeks half of them were able to leave the hospital, and within four weeks every case of beriberi was reported as cured by the attending physician of the hospital. Prior to May, 1910, polished rice was the staple article of diet in jails, lighthouses, charitable institutions, government vessels, and on public works, and beriberi was frequently present. Since May the use of polished rice has been prohibited by executive order, and beriberi has completely disappeared wherever other diet or unpolished rice was substituted. The results were so satisfactory that he believed that the time had come when the medical profession should be called to aid in securing legislation which would prohibit the use of polished rice for a period of several years at least, and thereby complete the last step in the test that promised so well to have a successful outcome.

The next paper, entitled "The Eradication of Beriberi from the Philippine (Native) Scouts by Means of Simple Changes in Their Dietary," was read by Major Weston P. Chamberlain, president of the Army Board for the Study of Tropical Diseases. The author showed that among the Filipino troops of the U. S. army prior to changing the

diet the monthly average beriberi incidence was approximately fifty cases, which was reduced by changing the diet to only a few cases per month, and during some periods the disease disappeared entirely, which had not heretofore been the case under previous diets. These results he attributed to the fact that the amount of polished rice in the ration was reduced and the amount of legumes increased. During the past six months the diet was further changed by substituting unpolished for polished rice. In brief, it may be stated that the experience had by the army showed that when polished rice formed the staple article of diet beriberi developed, and when a more mixed diet was used, or in other words, such constituents were added as are contained in the pericarp of rice, the beriberi disappeared.

The next paper, entitled "Rice as a Food," was read by Felix Hoxson, assistant in physiology, College of Physicians and Surgeons, University of the Philippines. In brief, it gave the chemical analysis of the different kinds of rice that are found in the Philippine Islands.

The last paper of the session, by the three members of the Army Board for the Study of Tropical Diseases, entitled "A Study of the Influence of Rice Diet and of Inanition in the Production of Multiple Neuritis of Fowls and the Bearing Thereof on the Etiology of Beriberi," was read by Major Chamberlain. This paper gave a large series of experiments that were undertaken by the board in producing experimental multiple neuritis in fowls. The conclusions reached by the authors were that multiple neuritis in fowls could be produced by simple starvation or by feeding a rice which contained less than 0.4 per cent. of phosphorous pentoxide.

The Nurse and the Public Health.—A. W. Goodrich states that today we have the training schools that Florence Nightingale hoped for, over 1,000, with 200,000 hospital beds and 29,000 pupils, but these 29,000 pupils are trained for the individual need of the institution rather than for wider service of the state. A study of any group of institutions in the United States would bear this out. A recent comparison of the statistics of 125 hospitals shows the division of services to be approximately thus: 70 per cent. surgical, 20 per cent. medical, and the remaining 10 per cent. to be divided between obstetrics and children, in favor of the former. All this simply goes to prove that the hospitals are training the nurses for hospital work, and yet the greatest need of the country is for intelligent nursing in the homes. The hospital that trains the nurse in surgery is doing service for that hospital mainly and is doing a minimum service for the state. The same is true of the hospital that trains strictly in any specialty, whereas the state needs nurses trained and experienced in all phases of nursing.

Fibrous Stricture of the Rectum.—J. P. Tuttle notes that stricture of the rectum is bound by no hard and fast rules as other conditions of this organ are; in fistula one may always say, incise; in hemorrhoids, clamp, or tie; in cancer, extirpate; but in stricture, the almost infinite variety of its causes, the changing physical characteristics, and the various methods of treatment, depending upon these causes and the state of the parts, call for exercise of greater judgment and experience than almost any other rectal condition.

Hemorrhagic Disease of the Newborn.—R. M. Green and J. B. Swift conclude that the parity and civil status of the mother, the fetal presentation, the duration of labor, and the complications of labor and the puerperium are factors of no significance as predisposing or determining causes of hemorrhagic disease in the newborn. The seasonal incidence and the occurrence of hospital cases in groups tend strongly to confirm the theory of the infectious etiology of the disease. The earlier the onset of the disease the worse its prognosis; after one week the prognosis becomes relatively, and after ten days, absolutely, good. Clinically the disease occurs in three fairly distinct types, the umbilical, the seromucous, and the purpuric, which have an approximate respective mortality of 60 per cent., 50 per cent., and 22 per cent. The gross total mortality is about 50 per cent. The treatment should be directed toward local hemostasis and increase of coagulability of the blood. Gelatine and rabbit serum are agents of proved value. Quiet and isolation are indicated in every case. Blood transfusion is a promising procedure which deserves further trial. The ideal treatment has not yet been demonstrated.

Medical Inspection of Schools in Boston.—S. H. Ayer notes that Boston was the pioneer in the work of medical school inspection, but has been outstripped in it by nearly all the large cities in the country which have taken it up.

A Simple Head Bandage.—E. C. Hill has improvised an arrangement by which he obtains ready access to the part, any desired degree of pressure on the maxilla, and an easily adjusted and secure bandage. All that is needed is an ordinary surgeons' cap of unbleached muslin, three safety pins, and a strip of gauze.

Trachoma.—S. H. Brown states that trachoma as it exists in America, and especially in Philadelphia, is a most attenuated form of the disease, particularly in the native born individual. These cases are of no greater importance than a host of ocular conditions, and while necessitating treatment do not call for isolation and segregation. Trachoma cases with discharge in America are more dangerous than those without; but no more dangerous than any other discharging ocular affection and not so much so as some. In American cities all "groups" of adults and children should be subjected to routine ocular examinations at regular intervals in order to detect new foci of the disease, but this does not imply that these patients should be subjected to rigorous quarantine measures. The disease is essentially chronic, and years may elapse before deformities occur, and the hardship quarantine thereby entails is obvious. Operative measures are unsatisfactory. Applications that lessen discharge retard the disease and make the patient comfortable.

Modern Care of the Insane.—M. Solomon in describing the system employed in the modern hospital for the insane has taken as a model the Government Hospital for the Insane, Washington.

Improvements in Cystoscopes.—L. Buerger states that by means of the Wappler lens prism and a combination of middle lenses, giving two inversions of the tube image, it has been found possible to conserve as much, and even more, light in a small catheterizing telescope than one has been able to retain heretofore in the large simple observation telescopes. The field of view has been also increased, resulting in an angular field of view showing a gain of 30°, or about half again as large as in the older instruments.

Prostitution and Venereal Diseases.—F. Bierhoff advocates the segregation of prostitutes, and their supervision by the Department of Health.

Transfusion of Blood.—A. L. Soresi describes a new method of direct transfusion of blood. His instrument is composed of two small metal cylinders which are put and held together by means of a small bar and a screw. Each cylinder is opened on its longitudinal axis by a simple pivot and at one end, a little below the edge, is encircled by a crown of small hooks, the points of which are turned toward the other end. The instrument does away with the necessity of opening the blood-vessels until they are ready to be brought together, so that the blood may flow immediately from one to the other. The surgeon is thus enabled to work on the blood-vessels while the blood is circulating in them; that is, while the lumen is naturally open, because it is full of circulating blood; therefore the blood-vessels, not being contracted and retracted, are easily grasped and secured by the instrument. Then the intima can without any difficulty be so inverted that the intima of the two blood-vessels can easily be brought in direct contact.

An Unusual Case of Poliomyelitis.—H. G. Harris considers the possibility of the colon bacillus as a causative factor in this condition. The interesting points in the case he reports are the length and the severity of the acute manifestations: the presence in the urine of the colon bacillus; the effect of hexamethylenamine; the symptoms indicative of meningitis and tetany; the relief of the symptoms following the lumbar puncture; the appearance of the paralysis on the tenth day and its disappearance a week later. Finally, it is his belief that the symptom complex tetany is a term not infrequently applied to atypical cases of anterior poliomyelitis. Also, that the question of whether colon bacillus infection may not cause symptoms characteristic of so-called tetany, poliomyelitis, or meningitis is worthy of future study.

Diabetic Glaucoma.—S. Moskowitz reports a case with the purpose of showing that diabetics stand eye operations well, and especially so when their glycosuria is diminished to a minimum by treatment and diet. He brings out the fact that the case was of diabetic origin and not coincident with the diabetes, and that the treatment for the disease had influence on the eye when the sugar in the urine was diminished or increased.

Treatment of Whooping Cough.—C. L. Henriquez has obtained good results with the use of a mixture of compound syrup of squills and of a syrup containing cocillana.

Infundibulin in Uterine Hemorrhage.—J. C. Scott notes the effect of extract of the posterior or infundibular lobe of the pituitary gland in stimulating the contractile powers of the uterus. He reports a case of severe uterine hemorrhage occurring in the course of carcinoma of the uterus, in which the hemorrhage was controlled by the hypodermic injection of 1 c.c. of a 20 per cent. infundibular extract.

Urethritis Caused by Tonsillitis.—By G. L. Hunner

See MEDICAL RECORD, January 28, 1911, page 173.

Huntington's Chorea.—W. F. Lorenz states that chronic progressive chorea in adult life seems to be far more prevalent in the Middle West than in the Eastern States of our country. There were but two cases of this type among the 2,430 admissions to the Manhattan State Hospital, New York, during the years 1900-1910, while at the same period there were two cases admitted in the Kankakee State Hospital, and five in the State Hospital at Mendota. It is worthy of note also in this connection that the twenty-seven cases reported by Hamilton were all from the Middle West.

Traumatic Psychoses.—B. Glueck comes to the conclusion that there is no psychic entity which can be recognized as a traumatic psychosis without a history of a definite relation of the mental disturbance to a preceding injury of the head, and, contrary to Kreuser's views, even what he terms endogenous psychoses can be caused by head injuries, as some of the author's cases show. The prognosis is favorable when there are acute mental disturbances, such as delirious or confusional states, while in the endogenous psychoses it is extremely bad. Head injuries may have a lasting bad effect on the individual as regards the finer functions of intellect without leaving him actually insane in the generally accepted sense of the term.

Prognosis of Gastric Ulcer.—G. R. Lockwood states that if one diagnoses ulcer too readily one is liable to include a large number of cases of chronic appendicitis and gallstone disease. The surgeon is inclined to take a more gloomy view than the physician because he only sees such cases as have been rebellious to medical treatment or where perforation has occurred. The patients in the severer cases, too, are the only ones who go to hospitals where they receive surgical treatment. According to Musser, the mortality from ulcer treated medically in private practice was only 3.1 per cent., as compared with 12.4 per cent. of those treated medically in hospitals. The aggregate average mortality as calculated by him is about 8 per cent. and this figure accords closely with the author's observation. Operation for gastric ulcer is attended with better results, according to the skill of the operator, *i.e.* from 2 to 3 per cent. by a skilled surgeon and from 6 to 8 per cent. by the average surgeon. Mortality after surgical operations for the condition, however, has been estimated at a little over 10 per cent., and this is affected by the fact that many physicians are very remiss in sending their cases to the surgeon. As regards the medical treatment, satisfactory statistics are lacking because the cases are not followed up sufficiently, but it may be said, from a study of statistics conformable to scientific requirements, that in the medical treatment about 80 per cent. of patients are apparently cured and that in hospital practice one-half of these and in private practice about one-quarter relapse. In the remaining 20 per cent., while the results are not brilliant, the patients are benefited to a greater or less extent by the treatment. As regards the end results of surgical treatment, Lockwood concludes that from 2 to 10 per cent. of patients will die directly or indirectly from the operation and that probably 15 per cent. will have little benefit from the treatment.

Vernal Conjunctivitis and Eosinophile Cells.—B. Pusey notes the discovery by Herbert that the conjunctival secretion in vernal catarrh is rich in eosinophile leucocytes and the confirmation of this discovery by several other observers.

Tonsil Dissector.—J. B. Greene describes a new instrument of this kind that he has devised.

Hemiplegia from Head Injury.—E. A. Babler states that, while hemiplegia due to cranial injury is perhaps a more frequent occurrence than is generally believed, this complication was present in only thirteen of the 614 cases of skull fracture admitted to the St. Louis City Hospital during the past five years. There were, however, in addition two cases of monoplegia of one leg and one of facial paralysis from this cause. The author notes that it is surprising to what extent the brain may be crushed and compressed without producing focal signs or permanent paralysis. Hemiplegia following cranial injury is a very serious complication, but the prognosis is more favorable in conscious patients than in those who are unconscious.

Tuberculosis of Cecum and Colon.—N. P. Walker reports a case of hyperplastic tuberculosis of the cecum and ascending colon in an insane colored woman, aged 30. The patient was operated on.

Traumatic Subdural Hemorrhage.—M. Solomon in comparing subdural with extradural hemorrhages sums up the main points in favor of a diagnosis of the former as follows: Subdural hemorrhage is the most common form of intracranial hemorrhage in the newborn. It is frequently associated with depressed and more especially with basal fractures of the skull. It is characterized by an absence of the periods of concussion and free interval and by the rapid onset of symptoms. The symptoms are usually those of a generalized compression, with marked depression and unconsciousness, practically from the very first, and the almost invariable presence of medullary symptoms, and the presence of blood in the cerebral fluid on lumbar puncture.

Electric Enema.—W. H. Dieffenbach states that in testinal obstruction and postoperative paralysis of the bowel are of such grave moment that a clinical note on this subject offering a new technique in its treatment has warrant for its publication. The method consists essentially in the employment of half-normal saline enemas in conjunction with a hollow rectal electrode connected with the galvanic current, followed later, if necessary, by faradization.

Gas Bacillus Infections.—W. R. Hewitt describes the symptoms of infection by the *Bacillus aerogenes capsulatus*. Excepting in a generalized infection operative treatment is the only resource and early interference before seventy-two hours, preferably amputation in malignant cases involving the limbs, will usually be life-saving. The infection occurs most commonly from contamination with street dirt which can be explained usually by the presence of manure. Next to this it occurs with infection from railroad dirt, and in the order named from elevator dirt and intestinal tract discharges. All wounds contaminated from these sources should be observed for this infection and treated if possible in such a way as to permit of easy inspection. Hence permanent bandages and plaster casts should be avoided so far as they interfere with this. If there is any suspicion of the gas bacillus being present cultures should be carefully made and the wound treated with hydrogen peroxide or oxygen preparatory to amputation if necessary. A fall in temperature to normal would seem to indicate the eradication of the gas bacillus infection, as in two of his reported cases. The disease is not very common, occurring in one out of an average of 1250 surgical cases and practically in all cases in which there is pulpification of tissue, which seems to diminish the resistance.

Cerebrospinal Pressure.—B. B. Crohn, after pointing out the disadvantages of the Quincke apparatus for determining cerebrospinal pressure and those of its modifications by Krönig, Wilms, Pfaundler, and others, describes a device of his own. The advantages claimed for the instrument are that it gives no opportunity for accidental escape of fluid, is compact and small, and can be thoroughly sterilized, and that no foreign substance is used to indicate pressure.

External Plantar Aneurysm.—C. M. Stimson and J. T. Rugh report a case of aneurysm of the external plantar artery as a sort of surgical curiosity. Search of the literature revealed only five other cases reported. The patient was a traveling salesman, aged 34, whose wife had had two miscarriages and who denied venereal infection. There were moderate arteriosclerosis and accentuated aortic second sound—otherwise his health was good. The swelling disabled him from his business. The sac when removed was found to be spherical in shape and 3 cm. in diameter. Recovery was good after ligation and removal.

Ankylostoma Infection.—A. E. Boycott continues his article on this subject. He notes the conditions which determine the prevalence of ankylostoma infection. Three are of outstanding importance—moisture, temperature, and fecal contamination of the soil, and to ensure the existence of the parasite in any place all three must be simultaneously favorable. In the tropics this coincidence is commonly found. In mines in northwestern Europe, on the other hand, infection is often rendered impossible because one of these three conditions is unfavorable. Fecal contamination is, or at any rate has been, everywhere pretty extensive, and most mines of any size are in parts either hot enough or wet enough. But relatively few underground works are at the same time and place hot enough and wet enough to give the parasite a reasonably good opportunity. If conditions are not unfavorable, the intensity of prevalence, as measured by the proportion of persons exposed who are infected and the proportion of those who have a large enough infection to make them ill, will vary as the product, rather than as the sum, of the degree to which moisture, temperature, and fecal contamination are coincidently suitable for the development of the increasing number of eggs which the soil receives as infection becomes more widespread and more intense among the human population. Thus, one may have every grade of prevalence, from the scattered cases which occur among the general population in the south of Hungary to the universal infection subsisting in Porto Rico, just as in Cornish mines, which are rather cool and dry, only 10 per cent. of underground workers are infected and none are sick, while at least 95 per cent. harbor the worm in hot, wet workings and 5 per cent. are too ill to work.

Myositis Ossificans Traumatica.—R. J. Godlee discusses the question of whether this condition should be called myositis and what is the evidence that it is due to inflammation of muscle. To the author it seems more probable that the essential things are first an injury to the periosteum, and, secondly, an effusion of blood; and that the injury to muscle and the inclusion of muscular

fibers in the callus are, so to speak, accidental, though it no doubt governs the shape and position of the new mass of bone. In other words, it is more analogous to what occurs when periosteum is stripped off in such operations as excision of the elbow, or in the cephalhematomata of infants, in which it is easy to demonstrate true bone at the margins of the clot, or to the formation of provisional callus in simple fractures.

Traumatic Myositis Ossificans—G. H. Makins notes that the frequency with which two muscles of the body, the quadriceps extensor femoris and the brachialis anticus, are affected seems to support the theory that the exciting influence is to be referred to bone-forming cells detached from the periosteum.

Bone Formation in Periosteum Separated by Injury.—A. A. Bowlby notes that the formation of a considerable swelling as a result of the separation of periosteum by the muscles is not a common occurrence, although, as the result of direct blows, such as kicks on the shin, it is frequently seen. But there are really a great many cases in which pain and impairment of the use of a limb are caused by the dragging of the periosteum off the bone where large muscles are inserted into it, and by the hemorrhage which results therefrom and from the formation of new bone. In most of these cases the swelling is slight and is often hardly noticed, but pain may persist for a long time unless the muscles are kept at rest.

Poisoning by Goatsbeard.—F. J. Smith reports a case of fatal poisoning from eating the seeds of *Tragopogon pratense*, or goatsbeard.

Diphtheria Carriers.—A. G. Macdonald reports a record of ninety diphtheria carriers. The presence or absence of an obvious pathological condition is no criterion of the fact of a carrier, of the length of carrier life, or of virulence. The length of carrier life seems to have no effect on virulence; bacilli have been demonstrated to be virulent after four and eight months in the ear and nose of different individuals. Carriers are found among those most intimately associated with other carriers or cases: at home between mother (nurse) and child, and child and child who play together; at school the carriers found are few and always closely associated (in play and not necessarily in schoolroom proximity) with some other carrier or case. The control of diphtheria depends (assuming contact of the case) on the control of the carrier. The carrier should be notified as a case of diphtheria, no matter of what age or sex, and due quarantine and observation should be maintained until satisfactory demonstration of the disappearance of the *Bacillus diphtheriæ*. Evidence points to the slow, inevitable, mechanical distribution of the disease which persists endemic in the undiscovered carriers. Epidemicity depends entirely upon the number and nature of the carriers; the headway that has been attained before preventive measures have been effectively used, and upon various sociological factors more or less under the control of the authorities.

Heart Failure from Use of Cocaine.—F. W. Price and A. B. Leakey report a case of grave and prolonged cardiac failure following the use of cocaine in dental surgery.

Deformities of Female Generative Organs.—J. A. C. Macewen reports a case of absence of the body of the uterus and right appendages, with the presence of a myoma and calcified dermoid. Intestinal obstruction resulted from the pressure of the tumor on the bowel. The author also reports a case of absence of the lower end of the vagina in a girl 16 years of age who presented symptoms resembling those of a case of appendicitis. The enormously distended vagina pushed up the body of the uterus against the omentum, causing the latter to be gangrenous.

Nuchal Lipomata.—Sir Jonathan Hutchinson notes that in the human subject nuchal diffuse lipomata are met with almost solely in males of middle age, and in those accustomed to drink malt liquor. Sex as well as habits of diet have something to say in the production of these hypertrophies, and especially with their location. In several instances in the human subject the author has witnessed definite subsidence of the tumors as the result of abstinence, and conversely a few weeks of beer-drinking will cause the tumors very perceptibly to increase.

Clinical Aspects of Excitement.—W. T. Munro presents illustrative cases and describes points in the differential diagnosis of mental exaltation or mania proper, alcoholic excitement or delirium tremens, excitement in general paralysis, katatonic excitement, semi-conscious epileptic states, and excitement in dementia precox.

The After-History of Thirty Cases of Movable Kidney Treated by Operation. A. R. Short.
The "Cardio-Splanchnic Phenomenon" of Abrams. W. Gordon.

Indigestion.—G. Rankin states that indigestion in its purely functional aspect may be divided conveniently into three varieties: sthenic, asthenic, and fermentative. Sthenic indigestion is found usually in an individual of full habit of body who has been accustomed to liberal eating and drinking. Asthenic indigestion is most commonly met with in young and badly nourished persons, who have suffered privations from insufficient food, overwork, and mental anxieties, and who have become in consequence anemic and neurotic. It has not inaptly been called "gastric myasthenia." Fermentation is, in the large majority of cases, a superaddition to a preexisting condition of indigestion. When it ensues upon the sthenic variety of the disorder, in addition to the ordinary manifestations there is a greater prominence of three symptoms—giddiness, vomiting, and eructations.

Hour Glass Contraction of the Stomach.—R. P. Rowlands states that this condition is not as rare as it is supposed to be, for he has operated upon six patients who were suffering from it during the past three years. The narrowing was due to the contraction of a simple ulcer in five, but carcinoma had been grafted upon simple ulcer in the sixth case. The condition would not have been recognized in at least three of these without the aid of the bismuth and *x*-ray method of examination.

Acute Dilatation of the Stomach.—G. G. Farquhar reports a case of this condition occurring in a girl following the eating of a pound of figs. Recovery followed operation.

Treatment of Appendical Abscess.—A. E. Maylard recommends the following method of treating the abscess cavity. This is freely wiped with a small gauze swab soaked in pure carbolic acid. An effort is made to reach every part of the cavity. A dry swab is then introduced to soak up any of the remaining acid, and immediately thereafter any amount up to half a teaspoonful of iodoform is put into the cavity, and with a blunt instrument smeared over its walls. A rubber drainage tube about a quarter of an inch in diameter is conducted to the lowest part of the cavity, and on one side of the tube a narrow strip of iodoform gauze is packed in zigzag fashion, just sufficient to fill the cavity; this, with the tube, is conducted out of the abdomen about the center of the wound.

Idiopathic Dilatation of the Colon.—W. Leggett reports a case of this condition occurring in an imbecile.

Cold Chamber Treatment.—J. G. Thompson and Professor R. Ross describe the effect of cold dry air in retarding certain infections. Experiments were performed on infected animals kept in a chamber maintained at a temperature of 20° F., and with a low humidity (40 to 60 per cent.).

Asiatic Cholera.—H. Stevens presents an analysis of 326 cases of Asiatic cholera.

Movable Kidney.—A. R. Short followed the after-history of thirty cases of movable kidney treated by operation. He found that complete or considerable relief was afforded in 20 out of 30 cases, treated by several different methods of operation. In at least 3, probably 4, cases the kidney again worked loose. Several of the failures were certainly due to a mistaken diagnosis as to the cause of the pain. No cases of slipping were found in 8 cases treated by the carbolic paint and gauze sling method, and followed from two to ten years.

The Cardiosplanchnic Phenomenon.—W. Gordon states that the so-called "cardiosplanchnic phenomenon" of Abrams, or difference in the percussion note over the lower part of the sternum obtained by comparing this note in the recumbent and standing positions, is absolutely contrary to fact.

March 20, 1911.

Acute Atony of the Stomach.—Schlesinger evidently refers to what is commonly known as acute dilatation. At least he hardly employs the latter term in his article, although it is conceivable that a normal stomach may be acutely distended. He discusses entirely what is known as the postoperative atony or dilatation. One such case was relieved by placing patient in the Trendelenburg position and using a stomach tube for drainage. Half a pail of water came away which possessed a distinctly feculent odor. In such a case the possibility of an occlusion of the small intestine must be taken into account. A study of the patient showed that the fecal odor was not constantly present. Intense atony of the stomach could occur without the latter—for the patient underwent the same gastric crisis several times in succession. To explain both sorts of crisis, it is necessary to assume the existence of some shutoff arrangement which may or may not be present at a given time. The arrangement which occludes the upper part of the intestine, must be a temporary reflex, else fecal matter could not enter the stomach. The problems involved must necessarily be difficult. The existence of acute atony or dilatation has even been denied. Autopsy records show that in many cases a kinking of the intestine above the duodeno-jejunal juncture may be found in operative cases. Other records purport to show a pyloric occlusive condition. Tandan sought to show that these occlusions could be prevented by the Trendelenburg position during operation. The mechanism in such cases was not sufficiently in evidence. In other cases as cited by Haberer, the occlusion was pathological and permanent. In other words nothing has transpired to prove the necessary occurrence of gastric atony after operation. To attack the problem from another point of view—to wit, the prophylactic—Kocher washes out the stomach before all gallstone operations. The author would improve upon this procedure by adding the Trendelenberg position in all operations. The importance of the problem is shown by the great activity in experimental lines, as suggested by the foregoing. It seemed quite impossible to imitate the conditions of acute gastric atony in man.

Acromegaly as a Result of Fright.—Pel of Amsterdam called attention to this association as far back as 1891. No one has called attention to any similar association during the 20 years elapsed. To-day Pel has added two cases to his first one. The first of these latter began in a married woman aged 25, who was shocked mentally by a gas explosion. Menstruation was suppressed for 9 months and then was resumed sparingly and irregularly. Gradually the hands, feet, and face began to enlarge. There was no change in the glandular organs, and the sexual apparatus became atrophied. The encephalon remained normal. Patient, although well, tired quickly. The *x*-ray showed enlargement of the sella turcica. There was no other evidence of pressure atrophy within the skull. The second case was in a woman aged 47, who complained of ready fatigue, general exhaustibility, affections of the psyche and vision, and enlargement of hands, feet, and face. Some 16 years before, while pregnant, patient was violently alarmed by a fire. Gestation not interrupted, no anomalies of puerperium or lactation. After the lactation period, the disease in question made its appearance. A climacteric resulted. The subject complained of pains in the head and face, arms, legs, hands, feet, and face. Vision was affected. In a few months acromegaly was apparent. At the present time, 16 years later, there was marked muscular weakness, including the heart—the picture of muscular hypotonia. The teeth are separated from one another. The spine is in a state of kyphosocoliosis. Patient has periodical epileptic attacks, or rather epileptiform attacks, beginning in the right arm or facialis, but becoming general and typical. The pupillæ of the eye were pale; the usual acuity and field of vision were much reduced. Hemianopsia was absent. These symptoms could be explained by a pressure on both opticus roots before the chiasm. The internal organs showed no anomalies. The sexual atrophy was marked in the highest degree. The headaches were one sided and in fact represented a sort of migraine. Röntgen investigation showed a marked dilatation of the sella turcica.

Münchener medizinische Wochenschrift.

March 21, 1911.

Chronic Constipation, Cardiac Weakness, Nephritis, etc.—Ebstein has already placed on record the occasional association of chronic constipation and insufficiency of the myocardium. Others have asserted that degeneration of the myocardium may be a direct consequence of coprostasis, although the author does not regard the change as more than functional. He comments on a personal case report as follows: The patient had progressive weakening of both sides of the heart for ten or twelve years. The right side weakening was shown by dyspnea, and the left side weakening by swollen liver, oliguria, and edema. The most interesting aspect of the case was the displacement of the heart from the constant tympanites, which showed that some element beside autotoxemia was responsible for the effect on the myocardium. Yet it does not follow that elevation of the diaphragm necessarily causes cardiac insufficiency; or at least such a condition is masked, and only after relief from meteorism does the patient know that the thoracic organs act more freely. The meteorism which causes this cardiac infirmity may include a dilated stomach; and every physician must know that the latter condition can cripple an already diseased heart, and even bring about acute heart failure. The author, however, adheres quite strictly to his theory that chronic constipation *per se* can cripple the normal heart, probably by mechanical means alone, the diaphragm compressing it continuously. The second problem discussed by the author is the association of chronic constipation with albuminuria and cylindruria. Unlike others he has not seen typical nephritis in this connection, but only the above named symptoms, which may be present in most of the cases of coprostasis of high degree. This may be due to chemical irritation from the absorbed products of coprostasis (for it is well known that nephrotoxic poisons may be formed in the intestine). They may also be due

to mechanical compression of the inflated intestines acting either directly on the kidneys or indirectly through the heart. We learn that in all cases cited by the writer the heart's resistance is either diffused or the heart itself displaced, with weakened action. He also warns in the diagnosis of nephritis before this cardiointestinal syndrome is excluded.

Pyocyanase for Diphtheria Carriers.—This substance has passed its nostrum stage and like salvarsan and other substances may be discussed as a legitimate accession to practical medicine. Prof. Sörensen of Copenhagen has used it extensively as a substitute or addition to toluol, menthol, iodine, etc., as a bactericide, especially in the convalescent stage. In other words he sought to sterilize the throat, etc., and thus eliminate bacilli carriers. Patients are not to be discharged from the Blegdam Hospital until bacillus-free. Despite all endeavors 5 per cent. of patients have to be discharged with bacilli in the throat. Of the 68 patients who had to be discharged in 1910 with bacilli in the throat, it does not appear that pyocyanase was able to improve upon the old remedies.

Banti's Disease Cured by Salvarsan.—According to W. Schmidt, the so-called Banti's disease may be a parasyphilitic affection. At least it yielded very promptly to salvarsan treatment, administered because of a heredosyphilitic history. This case is the more interesting because Banti had made the claim that neither lues, malaria nor any known cause had a part in the genesis of his particular syndrome. It has since transpired clinically that the Banti syndrome has been seen under the most varied conditions. In fact it is merely a syndrome and not a disease. The present writer has not only reported cases to support his thesis but finds that many recently reported cases have had a heredosyphilitic element.

Deutsche medizinische Wochenschrift.

March 23, 1911.

Treatment of Leukemia.—Sternberg naturally dwells most on radiography, which is so efficacious in certain leukemic cases, yet fails outright in others. It would appear that the rays should be exhibited under conditions not yet understood, in order to be efficacious. Arsenic has also been similarly exhibited in leukemia and its congeners (pseudoleukemia and lymphosarcoma), with the same irregularity in results. Leukemia patients frequently suffer from gastrointestinal anomalies, which may naturally be offset by proper treatment. Some leukemias under arsenic medication often exhibited phenomena due to arsenic alone; the latter have to be combated else they will be set down to the disease itself. This is more the case in the overaction of arsenic plus that of *x*-rays. The special symptoms of arsenical poisoning include herpes zoster and obstinate dermatitis of the mouth. Arsenical neuritis with paralysis of nerves is common. Beyond this mark arsenicism is not to be expected, and such results may be antagonized by an antiarsenical regimen. In conclusion the author would push the *x*-rays; using arsenic as a reservation measure. The ill effects of the latter should be supplemented or offset by a course of radioactive mineral waters, sunbaths, etc. Special complications, such as nosebleed, should be treated by the most approved remedies (cocaine, adrenalin). Radiography is always indicated.

Endothelioma Pleuræ.—Nearly every organ has a form of malignant disease which differs broadly from carcinoma and sarcoma. Fraenkel draws especial attention to a form of tumor which attacks every region within the thorax, and which may at first simulate tuberculosis or aneurysm. At a later period we have to exclude the typical lymphosarcomas, sarcomas, and cancers which are known to occur within certain parts of the thorax. Most of these originate in the mediastinum. Few develop from the pleura. But since 1895 data have accumulated as to primary growths in the pleura, which cause a pleural effusion. These were named as far back as 1870 by Wagner as endothelioma. The author has kept track of a number of cases since that period. The chief bone of contention has always been that these growths are cancerous. The differences are largely technical. The author admits that *intra vitam* no differentiation is possible. The endothelioma sets up all kinds of pleurisy, hemorrhagic, empyematous, etc., nevertheless a hemorrhagic pleuritis in the absence of near causes suggests an endothelioma of the pleura. The four cases cited, however interesting, throw no light on the mystery of the subject.

The Röntgen Primary Erythema.—Brauer discusses this subject in full. He is able to reduce his teachings to conclusions, viz.: 1. The Röntgen primary erythema is a facultative reaction. 2. It is independent of the quality of the rays. 3. The primary reaction is not due to heat or ultra-violet rays nor to fluorescence of rays, nor electric discharge. 5. The pigment of the skin exerts no influence on the Röntgen erythema. 7. The Röntgen erythema is due largely to the quantity of the rays. 8. The early pigmentation is due largely to the intensity of the erythema, etc.

Cystoscopy in Gestational Pyelitis.—Calmann insists that with the use of the cystocope much aid is afforded in diagnosis. We may determine the exact state of affairs, we may exclude the pressure of cholecysitis or appendicitis or other disease; we may arrive at a positive diagnosis, etc., and finally we reach the condition which may be controlled by therapy or surgical measures.

Fundus Findings in Heredo-Syphilis.—Japha concludes that in at least 66 per cent. of all cases of heredosyphilis there are alterations in the fundus oculi. This percentage may be established by a positive Wassermann reaction, together with isolated peripheral phenomena.

Desquamation and Scarlet Fever.—Schumacher states that desquamation is not a positive sign of recent scarlet fever, as scarlet fever can exist without any subsequent desquamation; and that desquamation may be the result of a number of constitutional diseases of long duration, as pneumonia and tuberculosis; or some local inflammatory condition of lengthy duration, as sunburn or poison-ivy poisoning; or the internal ingestion of some drugs, as arsenic; or the external application of strong antiseptics, as carbolic acid or formaldehyde gas.—*American Journal of Obstetrics and Diseases of Women and Children.*

Assistance from the School Physicians in Infantile Paralysis.—Mario Serena advocates the paying of especial attention by the school physicians to the orthopedic treatment of children who have recovered from infantile paralysis sufficiently to go to school. He thinks that it has been demonstrated that it is a mistake to wait for electric treatment in these cases until all the early symptoms have subsided. The electricity should be begun as soon as the health of the little patient will permit it. Massage and passive movements are also of value in these cases to preserve the integrity of the paralyzed muscles and to prevent contractures. After the case has in a measure lost its interest for the family physician, and the child has returned to school hampered by his disability, he is apt to go ahead mentally, while he is unable to take part in the games of his fellows, and precious time is lost and atrophy and contracture occur, which render it difficult to get a good result when surgical measures are undertaken. If the school physician would take pains to see that these cases are under good orthopedic treatment the benefit would be incalculable and we should have fewer candidates for the institutions for incurables.—*Gazzetta Medica di Roma.*

Book Reviews.

Hygiene and Public Health. By George M. Price, M.D., Author of "A Handbook on Sanitation," "Tenement House Inspection"; Inspector, New York State Tenement Commission, 1894; Medical Sanitary Inspector, New York Department of Health, 1895-1904. Series edited by Victor C. Pederson, A.M., M.D., Philadelphia and New York: Lea and Febiger.

This is a valuable addition to our books on Hygiene and Public Health. It is small, being a mere epitome; but the subjects have been well chosen, and the epitomization has been skillfully performed. The author has had a wide experience, and writes out of a full knowledge of his subject. For those preparing for an examination on hygiene this little book is particularly adapted; it is well arranged, concise, and accurate.

Bacteriology and Surgical Technic for Nurses. By Emily M. A. Stoney, Superintendent of the Training School for Nurses, St. Anthony's Hospital, Rock Island, Ill.; Author of "Practical Points in Nursing," "Practical Materia Medica for Nurses," etc. Third Edition, thoroughly revised and enlarged. By Frederic Richardson Griffith, M.D. (Univ. of Penn.), of New York; Surgeon, Fellow of the New York Academy of Medicine. Illustrated. Philadelphia and London: W. B. Saunders Company, 1910.

This new edition differs but little from its predecessors. A few pages have been inserted in the chapter on Diet Recipes, and the glossary has been enlarged. Much of the book remains as in the first edition. Some of the information in the glossary might be changed with advantage; the official salt of cocaine is the hydrochloride, and not the hydrochlorate, the latter having been displaced several years ago. The book is well known to nurses, and will, as a rule, be found to be a reliable guide.

Physical Chemistry. Its bearing on Biology and Medicine. By James C. Philip, M.A., Ph.D., D.Sc., Assistant Professor in the Department of Chemistry, Imperial College of Science and Technology, London. New York: Longmans, Green & Co.

This book is based on a course of lectures delivered to biological students at the University of London, in 1909. The author presents a systematic exposition of physical chemistry in so far as it has a bearing upon biological and physiological problems. The work is well planned, clearly expressed, and is more readable than works on chemistry are apt to be; the author has wisely avoided the use of mathematics as far as possible. In view of the growing importance of physical chemistry, and the paucity of suitable works on the subject, the author is to be congratulated on his success in supplying students of medicine and of biology with a small book specially adapted to their needs. The subjects treated in the volume are: Gases from the standpoint of experiment and theory; Diffusion phenomena; Absorption of gases by liquids; Osmotic pressure; Comparison of osmotic pressures; Isotonic solutions; Permeability and impermeability of membranes; Vapor pressure, boiling point and freezing point of solutions; Behavior of salts, acids, and bases in aqueous solution; Electrolytic dissociation, physical and biological applications; Colloidal solutions; Separation of colloids from their solutions; Absorption; Chemical equilibrium and the law of mass action; and the velocity of chemical reaction. The book is commended to all who are interested in chemistry, and in the modern problems, physiological and therapeutic, based upon that science.

State Registration for Nurses. By Louie Croft Boyd, R.N., Graduate Colorado Training School for Nurses, connected with City and County Hospital, Denver, Col.; Post-Graduate Presbyterian Hospital, Chicago, Ill.; Member Colorado State Board of Nurse Examiners, 1905-1909; Certificate of Hospital Economics, Teachers' College, Brooklyn, N. Y., 1908-1909. Price 50 cents. Philadelphia and London: W. B. Saunders Company, 1911.

This little pamphlet contains a summary of the laws in the United States governing the registration of nurses. It contains all that a nurse is likely to require in the way of information on the subject: The requirements for registration, fees, reciprocity, exemptions, rules for recording certificates, and an extensive bibliography. Most of the information is arranged in tabular form, but unfortunately the States are not placed alphabetically; hence, the information is not as readily available as it might be. So far as we know this is the only available work on the subject, and it should prove of the utmost service to all graduate and pupil nurses.

Über die Natur und die Herkunft des Trachomerregers, und die bei seiner Entstehung zu beobachtende Erscheinung der Mutierung des Gonokokkus Neisser, von Prof. Dr. Hans Herzog, Berlin. Mit 2 lithographierten Tafeln. Berlin und Wien: Urban und Schwarzenberg, 1910.

In this work of 51 pages Herzog endeavors to show that there is a transition form of the gonococcus which is identical with the minute granular bodies in the chlamydozoon of trachoma. He is of the opinion that in some cases of gonococcic blenorrhea the gonococcus ("macrogonococcus") may pass into the involution form ("microgonococcus") and in this form give rise to the chlamydozoon of trachoma.

The History of Medicine. Philosophical and Critical, from its Origin to the Twentieth Century. By David Allyn Gorton, M.D. In two volumes. Vol. I, Vol. II. Price $6.00. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1910.

These two volumes form a very praiseworthy addition to the contributions in medical history by American writers. The first volume is truly admirable and contains succinct biographies of an unusually large number of the personages who had a share in the upbuilding of medical knowledge. These are appropriately woven into a continuous narrative in which the development of the healing art from its earliest known beginnings to the commencement of the nineteenth century is well portrayed, so that the volume is both agreeable to read and useful for reference. The second volume, however, in which the story is carried on to the present day, offers many opportunities for criticism and falls far short of its fellow. For example, it seems, to say the least, an error of judgment to devote twenty-five pages to Christian Science and Osteopathy and to biographies of their founders, but not even to mention the name of Semmelweis or his epoch-making struggle to gain recognition for the correct conception of the nature of puerperal fever. Again, in the brief paragraph allotted to Oliver Wendell Holmes no reference is made to his highly important efforts in the same direction, while the pages devoted to Meigs, the persistent and virulent opponent of the theory of the infectiousness of childbed fever, are laudatory in the extreme. Again, it is a little astonishing to find in a serious work on the history of medicine a number of pages given up to extolling the merits of a certain well-known (and no doubt thoroughly commendable) pharmaceutical firm, mentioned by name, together with long excerpts from its advertising literature. The tribute to the New York College of Pharmacy is well intentioned, but the author's knowledge of that admirable institution appears to extend no further than the year 1895, for he reproduces on page 79, apparently with the idea of illustrating the excellence of the instruction now given, a schedule of the curriculum for that year, and no mention is made of the union of the college with Columbia University that took place some years ago. Very recent advances in serology, etc., are spoken of but no reference is made to the work of the last few years in the domain of syphilis, and on page 436 we find "the typhoid germ, the little animal that has for centuries caused the awful ravages in Peyer's glands. It is a question by no means decided, whether the germ of typhoid is the sole cause of that fever, or not." A few lines lower it is stated that, "The serum of the anti-gonococcus is made," etc. The printer's devil also has been unusually successful in making havoc of the quotations from foreign languages, and the examples to be found on pages 26, 93, 217, 340, and 341 are particularly weird. Attention has been called to these defects because they are typical of easily remediable blemishes in a work that is in the main of exceptional excellence. It shows wide reading and profound scholarship, and will no doubt find a permanent and valued place in American medical literature.

The Sexual Disabilities of Man and Their Treatment. By Arthur Cooper, Consulting Surgeon to the Westminster General Dispensary; formerly House Surgeon to the Male Lock Hospital, London. Second Edition, revised and enlarged, $2.00. New York: Paul B. Hoeber, 1910.

A practical experience of thirty years has enabled the author to present an eminently useful volume on this subject, useful both to the student who receives scant knowledge of sexual disabilities in his medical curriculum, and to the general practitioner who is frequently called upon to treat such disorders.

Society Reports.

MEDICAL SOCIETY OF THE MISSOURI VALLEY.

Twenty-third Semi-Annual Meeting, Held at St. Joseph, Missouri, March 16 and 17, 1911.

The President, Dr. Donald Macrae, of Council Bluffs, Iowa, in the Chair.

The Present Status of Salvarsan.—Dr. Alfred Schalek of Omaha said it was premature and risky to let a patient with syphilis go with one or only a few treatments with this agent. Syphilis was still a serious disease which required prolonged and thorough attention. Salvarsan had not as yet been proven to be greatly superior to mercury, and while it acted more rapidly on some lesions and might be of benefit where mercury was powerless, only time could tell whether or not the results would be more permanent.

Dr. C. A. Good of St. Joseph said that salvarsan quickly caused a disappearance of the primary chancre and mucous patches, but it was doubtful whether it would drive the spirochetes completely from the body. In his experience the mucous patches were very quickly controlled by the use of salvarsan. The induration and the enlarged bubos in a few cases had not disappeared.

Dr. T. M. Paul of St. Joseph said there had been a tendency to promise a syphilitic that one injection of salvarsan would practically cure him. This was unfortunate, because if later on the disease was not annihilated by one injection the man was imbued with a false idea as to his true condition.

Dr. Frederic S. Mason of New York City stated that while salvarsan might not be as good as mercury when it was used the acute symptoms were relieved quickly. He mentioned the case of a woman who had the acute lesions of syphilis and was attending to her business, and she received injections of salvarsan and within a week practically all the lesions disappeared. This was the principal advantage in using this agent.

Dr. S. Grover Burnett of Kansas City reported a case of acute delirium following the chloroform habit.

Difficulties Encountered in Late Operations for Intestinal Obstruction.—Dr. Herman E. Pearse of Kansas City said that by observing the following procedures the late cases of intestinal obstruction could be saved: 1. By emptying the bowel at first operation and allowing time to recover from toxemia before resection was practised, unless gangrene should forbid. 2. This should be done by employing the long intestinal tube and emptying the distended bowel as the first step after finding the obstruction, closing the wound after providing escape. 3. By the use of a glass tube of Paul or the rubber tubes with depressed external grooves, as advised by Andren Marro, to convey the toxic fecal matter beyond the wound, thus securing primary union and safety from abscess. 4. By bringing the bowel edges out of the incision beyond the skin and substituting the open treatment by a nurse and water washing for the closed method of filthy gauze and pads of cotton. 5. By employing a second and even third operation to complete the work when the patient had recovered from the effects of the obstruction and vomiting.

Dr. John E. Summers of Omaha said that sometimes in cases of strangulated hernia, where gangrene was present, one could establish an artificial anus by cutting into the gut, allowing it to remain until the circulation was re-established, and then an operation could be done later. If drainage was carried out it was wise to wash out the gut through a tube.

Dr. C. Lester Hall of Kansas City, Mo., differed with the essayist in regard to the incision. He said we could open the abdomen more widely and freely and reach parts of the abdominal cavity better through a median incision, and there was less trouble through that incision in the after treatment, and union was better there than in any other part of the abdominal wall.

Dr. O. Beverly Campbell of St. Joseph agreed with the essayist that a good place to make the incision was about the border of the right rectus, because there was more trouble in the right side in intestinal obstruction than anywhere else, and because of the fact that one wanted to drain in the median line. Therefore, he would favor the incision at this place in most cases.

Dr. S. H. Smith of Omaha reported a case of intestinal obstruction in a woman. The obstruction was caused by three constricting bands around the sigmoid flexure. These bands were cut. There were adhesions around the cecum which were broken up. Three days after the operation the patient had natural bowel movements without the use of purgatives.

Dr. F. H. Clark of El Reno said that shock in abdominal operations came more from the rough handling of the intestines than from any other single thing that entered into surgical work in the class of cases under discussion. A prominent surgeon told him not long since that he attributed his remarkable success to two things: First, he had acquired a technique which enabled him to get in and out of the abdomen in a much shorter time, and, second, he had learned to handle the intestines just as gently as it was possible to do so.

Dr. John P. Lord of Omaha stated that when there was a gangrenous gut to deal with, he believed it should be excised; then we would have an open bowel and could drain. We should not pack it with gauze and cover it with rubber tissue. The Murphy button tempted one to make an immediate anastomosis, which would be the means of causing the patient to suffer from a toxemia that killed so many patients that had so-called secondary shock. He did not believe in secondary shock unless it was a secondary hemorrhage.

Dr. S. G. Zink of Leavenworth reported three cases of fecal impaction, and said he had found that by using a twenty-five per cent. solution of peroxide of hydrogen, and putting the patient in the knee-chest position, or exaggerated Sims position, with the head low down, one of two injections of eight ounces, followed by irrigation, would break up these fecal masses.

Dr. C. H. Wallace of St. Joseph said that for the average surgeon who met these cases only occasionally he was satisfied that the simpler method of drainage by the introduction of a large tube would result in a greater saving of life than more extensive work.

Dr. Jacob Geiger of St. Joseph said that early and correct diagnosis was most important. It was easy to say what to do, but every case was a law unto itself, and when the surgeon had a case of acute intestinal obstruction and opened the abdomen and recognized the pathology, then he had to use his brains to determine what was best to do.

Dr. V. L. Treynor of Council Bluffs, Iowa, believed that if efforts were directed toward a more certain and early diagnosis it would simplify the treatment of these cases very materially. He did not like to hear the internists criticised for so-called neglect when the surgeon himself was sometimes incapable of making a diagnosis when he was called early.

Dr. C. C. Conover of Kansas City, Mo., said that modern methods of diagnosis had been improved so wonderfully in the past four or five years that most internists could make a diagnosis of intestinal obstruction, and they did not need to wait and call in a surgeon to tell them what was the matter with the patient.

Dr. H. M. Clark of Platte City, Neb., said that when country practitioners called in surgeons and they operated

on cases of intestinal obstruction and lost forty or fifty per cent. of them, he thought the practitioner could do nearly as well himself.

The Roentgen Ray in Postoperative Cases.—Dr. R. D. Mason of Omaha showed the value of the *x*-ray in cases where operation had been done and advised its use in all post-operative work where malignancy was suspected. He pointed out the fallacy of waiting until a return of the disease appeared before beginning the use of the rays.

Treatment of Tuberculosis.—Dr. Granville N. Ryan of Des Moines, Iowa, presented a preliminary report of five cases of tuberculosis treated with Carl Spengler's tuberculosis immune blood, and concluded that (1) it was the most effective agent in fighting tuberculosis that had come under his observation. (2) Perceptible lysis might be obviated in a number of cases by adopting the slow method of immunization. (3) The first signs of improvement were found in the subjective condition, lowering of temperature, increase of appetite, freer respiration if dyspnea was present, increase in weight, more restful sleep, decrease in cough, sputum, and tubercle bacilli; also disappearance of râles during the first few weeks. (4) It had been his experience that the toxic pulse persisted for some time after the disappearance of other symptoms. (5) In moribund patients its value had been chiefly in rendering them more comfortable. (6) Acute colds, to which these patients were highly susceptible, and other complicating diseases, must be dealt with according to indications.

Oration in Medicine.—This was delivered by Dr. Heinrich Stern of New York City, who selected for his subject "The Decay of Nations." The address was thoughtful and scholarly, the author receiving the undivided attention of a large medico-lay audience throughout its delivery.

The Rôle of Tuberculin in the Diagnosis of Pulmonary Tuberculosis.—Dr. Logan Clendening of Kansas City, Mo., reviewed the methods for the early diagnosis of this disease and said: 1. In infants and children the von Pirquet test was of great value and positive; the younger the child the higher its value; it was somewhat less valuable if negative. 2. In adults there was no method of using tuberculin for diagnostic purposes that had uniform value in all cases. The subcutaneous method was probably the best.

Colica Mucosa.—Dr. J. M. Bell of St. Joseph spoke of the dual aspect of this disease and said that his experience with it led him to believe the enteroptotic habit *plus* autointoxication and constipation was the foundation upon which the disease was based, the neurosis being secondary. When the digestive tract was restored a normal state of equilibrium was obtained.

Local Anesthesia with Quinine and Urea Hydrochloride.—Dr. C. M. Nicholson of St. Louis was convinced from experience with thirty-two cases that quinine and urea hydrochloride was destined to occupy a prominent position as a local anesthetic. The greater length of time required after the injection of the quinine urea hydrochloride before the anesthetic effect was fully manifest was its principal disadvantage.

In the discussion several speakers related their experience with this agent and said that their results had been very gratifying.

Suggestions for the Application of Lactic Ferments in Genitourinary Work.—Dr. Frederic S. Mason of New York City said that these ferments had a wide field of usefulness in the treatment of diseases depending on invasion of the gastrointestinal tract by pathogenic organisms since they inhibited the growth of the Klebs-Loeffler bacillus and many other organisms. Dr. Holbrook Curtis and Otto Glogan of New York had used suspensions of lactic ferments in bouillon successfully in the treatment of suppurating discharges from sinuses and nasal passages as well as from the ear. The speaker had only had opportunity of confirming these results in two cases of suppurating otitis. He described the technique for using the lactic ferment crayons in acute gonorrhea in the male, and did not claim that they were specific in the treatment of this condition, for the work done was too incomplete, but the results obtained were sufficiently encouraging to warrant a more extended trial.

Peritonization in Abdominal and, More Particularly, Pelvic Surgery.— Dr. John E. Summers of Omaha said by peritonization or peritoneoplasty was meant the covering over by peritoneum of all tears, lacerations, and losses of substance of the peritoneum due to surgical procedure. In some cases the peritoneum might be separated from the abdominal wall, commencing at the lower angle of the incision towards the space of Retzius, or at the sides, freeing a great part of the bladder likewise. These flaps were sufficiently large to cover over the posterior wall of the pelvis. In other cases, of which the author had had several examples, the technique consisted in transporting the sigmoid flexure across the pelvis and suturing it in such a way that all raw surfaces were covered over. The sigmoid was only fixed below and was almost always sufficiently mobile to be carried across the pelvis to the right side as far as the cecum. When the uterus was preserved the sigmoid was sutured to the lateral walls of the excavation and across the fundus of the uterus. When the uterus was sacrificed the sigmoid was sutured to the lateral walls of the excavation and to the bladder. Drainage should be made through the vagina. Amann emphasized the fact that this technique was particularly advantageous when septic pus or genital abscesses communicated with the intestine—for example, a pyosalpinx, or a suppurating tumor of the ovary, opening into the large bowel. Again, when there coexisted a genital abscess with a perforative appendicitis. The intestinal sutures were situated under the protection of the cavity drained and were extraperitoneal. Two vital principles were involved in peritoneal autoplastic surgery: First, the more vital principle, the prevention of infection; second, the prevention of post-operative intestinal obstruction.

Care of the Hypertrophied Prostate.—Dr. F. H. Clark of El Reno, Oklahoma, said the responsibility for early diagnosis and advice must of necessity rest with the family physician. While this condition usually came on with advanced age, it might occur even in childhood. Operative procedure was the only treatment that offered hope for a permanent cure and a comfortable life after operation. The operation which presented the lowest mortality was through the lower perineal route. We should never forget that ten per cent. of these hypertrophied prostates became malignant if allowed to go on, and that our only hope of avoiding that was an early operation. We must not forget that we should continue to sound these cases following operation until we were certain there would be no contraction of the scar formed that might serve as an impediment to the free flow of urine. Just how long this would take must be governed by each indiviual case.

Dr. W. E. Engelbach of St. Louis gave skiagraphic demonstrations of some unusual conditions in the chest.

Poliomyelitis Anterior Acuta.—Dr. L. A. Skoog of Kansas City, Mo., reported three cases of this disease in the same family at the same time.

The following papers were also read: "Should Venereal Infections Be Classed and Reported as Contagious Diseases?" by Dr. T. M. Paul, St. Joseph, Missouri; "Extreme Edema of the Cecum and Ascending Colon Following a Gangrenous Appendicitis," by Dr. L. J. Dandurant, St. Joseph, Missouri, and "An Unusual Case of Dilated Capillaries," by Dr. William Frick of Kansas City, Mo.

Pathological Society of Philadelphia.

At a stated meeting held January 12 Drs. Alfred Stengel and Marks presented a communication entitled "Report on Six Cases of Trichiniasis." All exhibited varying degrees of eosinophilia, three occurred in one family, and one terminated fatally. The diagnosis was confirmed by detection of the parasites or the ova in the stools or of the adults in the muscular structures. Drs. Ward Brinton and Randle C. Rosenberger reported a case of "Uncinarial Infestation in an East Indian." The patient had been in the United States for but a short time, and in the diarrheal discharges were found roundworms, the whipworm, and the hookworm, *Necator americanus*. There was a moderate increase in the eosinophile leucocytes. Drs. George W. Norris and A. F. Jackson presented "The Heart, Brain, and Spinal Cord from a Case of Cerebrospinal Meningitis." The patient had had a discharge from one ear, but this did not appear to be the source of the meningitis. The blood contained an increased number of leucocytes, with a disproportionate number of polymorphonuclears, while the meningitic exudate contained the *Diplococcus intracellularis meningitidis*. The mastoid cells were broken down on the side of the diseased ear, but the pus in this situation contained streptococci. Dr. Jackson presented on behalf of Drs. Norris and G. F. Lull "The Genitourinary Tract from a Case of Prostatic Hypertrophy and Chronic Cystitis, with Cystic Calculus and Ascending Infection of the Ureters, Causing Pyelitis and Suppurative Nephritis." The walls of the bladder were greatly thickened and the mucous membrane rugous, and the pelvis of the kidneys was greatly distended. The bladder contained a calculus composed principally of phosphates and carbonates. Dr. Thomas H. Montgomery, Jr., presented a communication entitled "The Cellular Basis of Sex-determination." He pointed out that the faculty of reproduction resided only in the ovum, the sperm possessing the property solely of fertilization. The question of sex is determined long before fertilization takes place and is not affected by any conditions arising subsequently. Dr. Alonzo Engelbert Taylor presented a communication entitled "The Present Status of Ferment Activators (Hormones, Kinases)." He defined a hormone as a substance generated by a gland and inciting activity in another gland by being carried through the circulation and acting directly on this gland as a chemical body without the intervention of the nervous system. The most noteworthy hormones were contained in the secretions of the thyroid gland, the adrenals, and the hypophysis and the internal secretion of the pancreas. An activator is a substance that excites or greatly increases the chemical activity of another body with which it is brought in contact. Zymoexcitors have a similar effect upon ferment activity. The theories on which these terms are based are not altogether new, as is indicated by the existence of such terms as actor, inductor, and adductor.

At a stated meeting held January 26 a symposium was held on "Protozoan Diseases." An elaborate exhibition was given of protozoa affecting man and lower animals and of mosquitos, flies, and other insects acting as disease-carriers and of pathological specimens illustrating protozoan diseases. Dr. Wm. Pepper read a paper on "Malaria," in which he traced the evolution of our knowledge of this most antagonistic to trypanosomes, but some combination gregate has perhaps caused more destruction than any other. He described the several types of parasites and their development in the conveying mosquito and subsequently in the infected individual. Dr. Henry J. Nichols, U. S. A., presented a communication entitled "Observations on Natural and Experimental Yaws." He described the peculiar lesion of the disease and he recited the fact of its occurrence in tropical countries, especially in children, much in the same way as measles. The lesions contain the causative organism, the *Spirocheta pertenuis*, which can be transferred to other animals and give rise to the disease in them. It is generally agreed that the spirochete of yaws and that of syphilis and that the diseases themselves are different and distinct. Dr. K. F. Meyer presented a communication entitled "The Piroplasmoses—East Coast Fever; Texas Fever; Piroplasmosis of Horses, Donkeys and Mules." He described these several affections and pointed out their individual characteristics on the basis of a considerable personal experience on the East Coast of Africa. Dr. Benjamin T. Terry of the Rockefeller Institute presented a communication upon "The Newer Chemotherapy of the Trypanosome Infections." He recited the successive efforts to secure a substance that would have an affinity for and be destructive of the parasites in the system—parasitotropic, without having a special affinity for and being destructive of the organism itself—organotropic, and he outlined observations illustrative of the theory along which the studies were carried out. It had to be determined why some chemical substances proved active in the test-tube and not in the human body and vice versa, as well as active both in the test-tube and in the human body. By this mode of procedure it was found that arsenic was most important and widespread disease, which in the ag had to be provided in which the toxic effects of the metal could be averted. In this way dioxydiamidoarsenobenzol came to be prepared. After elaborate experimental observations on lower animals the remedy was employed under strictest precautions on man, and the results have proved most gratifying.

New Instruments.

A CHEAP, PRACTICAL EXTENSION APPARATUS AND SACRAL SUPPORT FOR APPLYING PLASTER SPICA TO THE HIP, THIGH, OR KNEE.

By WALTER G. STERN, B.S., M.D.,

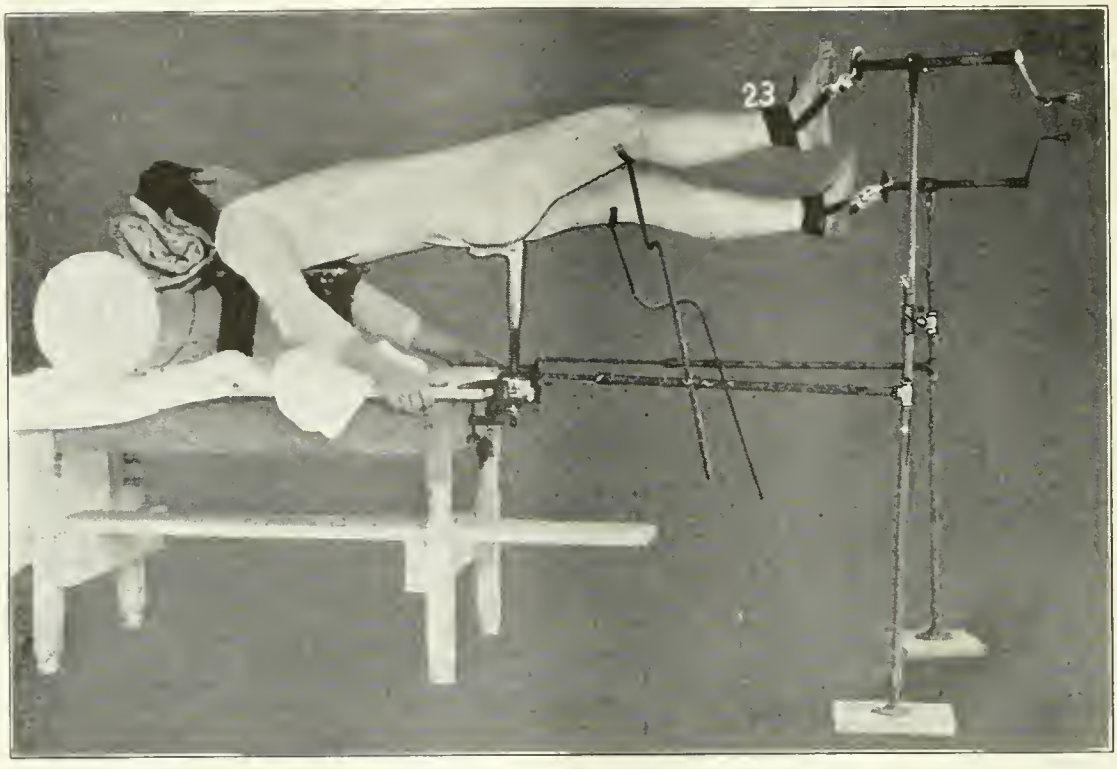
CLEVELAND, OHIO.

FELLOW OF THE AMERICAN ORTHOPEDIC ASSOCIATION; ORTHOPEDIC SURGEON TO THE MT. SINAI HOSPITAL, ETC.

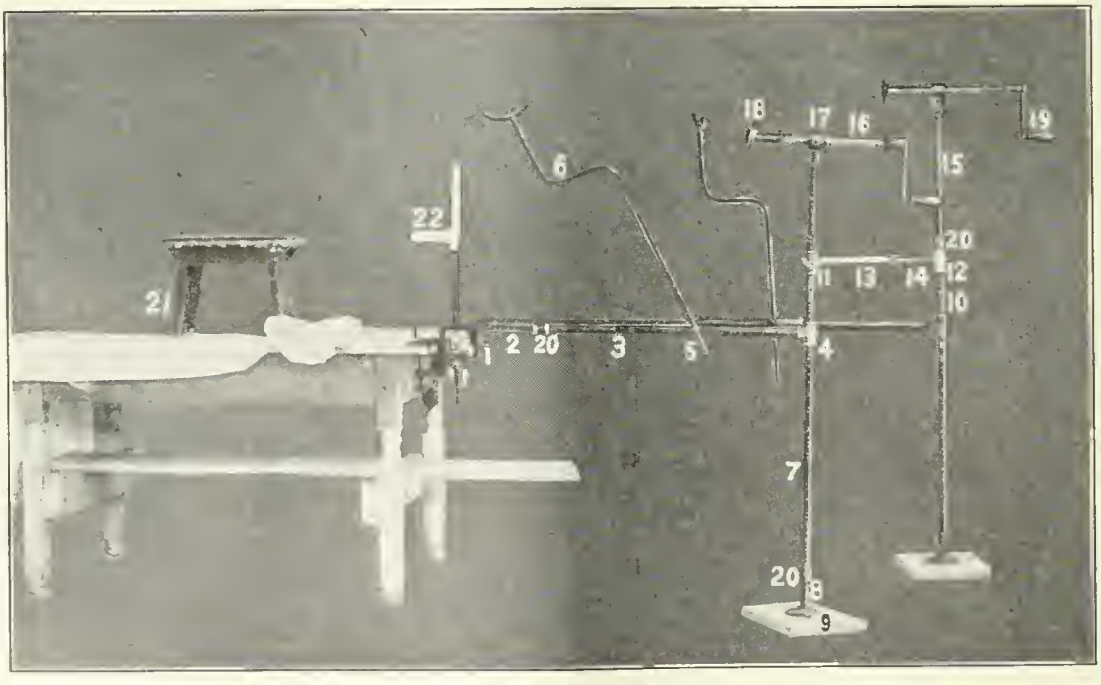
The lack of suitable instruments is, in the majority of cases, the reason why the general surgeon and practitioner are still following out many arthopedic operations and manipulations which are to-day distinctly not the methods of choice of those who have the facilities in the way of suitable apparatus. For example, the general surgeon performs the longer and more hazardous bloody operation of osteotomy for the correction of bow legs or knock knees in children, not because it is to-day the more favored operation, but rather because in his instrument case he finds the necessary chisel and mallet and lacks the Grattan or other osteoclast with which the skilled operator can correct these deformities bloodlessly, without the least danger, in less time than it takes to scrub up the patient for the open operation.

One of the most unsatisfactory procedures on the part of the general medical and surgical professions alike, has been the application of a plaster cast to difficult parts of the body, especially the hip and thigh after fracture or hip joint disease. The cause for this lies almost wholly in the lack of suitable rests for the sacrum, and apparatus for firmly holding and making traction upon the legs and thigh while the cast is being put on. There are, it is true, many excellent forms of hip extension apparatus

on the market, one of which was described in this journal several years ago, but its excessive cost ($300) and the length of time necessary to complete it to order (six weeks), almost precludes its use by all except the specialists, who are most likely to have special apparatus of their own design for the same purpose.



Realizing this, it has been my purpose to devise suitable apparatus for orthopedic procedures which would be so cheap, yet practical, that the practitioner could afford to get one even for a single case, and so simple that any country blacksmith, garage mechanic, or plumber could make them in very short order should occasion arise for their immediate want. The hip rest and extension apparatus herewith submitted is made entirely of parts which can be purchased from any wholesale blacksmith's or machinist's supply house, or, what is better in some parts of the country, selected from the catalogue of the larger mail order houses in Chicago. The only exception is the special table clamps made from my own patterns, but even here, in an emergency, small blacksmiths' or machinists' vises might serve the same purpose. The apparatus is designed to be used on an ordinary kitchen table, but is adjustable to fit any table up to four feet in height. As will be seen from the cuts, it consists of a central clamp holding the sacral support and two adjustable extension members, one on either side of the sacral support, fastened to the table with clamps and



united at their distal end by a telescoping and sliding brace. The whole apparatus is made out of ½-inch galvanized iron pipe and fittings and 9-16-inch round bar steel rods sliding in them. (By ½-inch pipe the nominal size as it is ordinarily known in trade is meant. Its actual inside diameter is .62 inch, so that a 9-16-inch rod slides freely without lateral motion within it.) The large screw, which is fitted with a crank to provide the fine adjustment of the extension is an ordinary carpenter's bench vise screw (costing 25 cents), with the Tee for the handlebar sawn off just beyond the collar, which latter is retained and fastened to the screw in its normal position for the purpose of retaining the swivel face plate (also a part of the 25 cent screw), to which the leather cuffs holding the feet are attached with harness bolt snaps. The female part of the screw (No. 17) is rounded off and is attached at the end of the upright bar. It can also be fastened to the upright by means of a yoke bolted to the bolt holes of the original female screw. The coarse adjustment is made by sliding rod No. 2 into pipe No. 3. The ends of the pipes which carry the thumbscrew (No. 20) to tighten the adjustments are reinforced by ½-inch galvanized unions, which are screwed flush with the pipe; the holes are bored through both union and pipe, are ⅜-inch size, and are tapped with a ¼-inch 20-thread tap. The thumbscrews are ¼-20 size. The size and description of the various parts are as follows: No. 1. Special table clamps, three in number, round holes for extension apparatus, square hole for sacral support. No. 2. 9-16-inch round steel bar L shape, smaller leg fitting into table clamp, 4 inches long; long leg sliding into No. 3 and making coarse adjustment of apparatus, 24 inches in length. No. 3. Pipe 24 inches in length. No. 4. ½-inch Tee. No. 5. Malleable iron chain swivel, No. 2 size (cost 3 cents), fitted at each end with thumbscrews. The larger eye is filed out to slide over No. 3, while the smaller eye is drilled out with a ½-inch drill to accommodate knee support No. 6. This makes an adjustable universal joint so that knee support can be swung and fastened with the thumbscrews in any conceivable position of the knee. No. 6. Knee support 36 inches long; upper cross bar on swivel pin. No. 7. Pipe upright 24 inches long. No. 8. Steel extension rod 12 inches long with ¼-inch thread at lower end. No. 9. ½-inch pipe flange fastened to 8 x 8 board, fitted to No. 8 by means of a ½-¼-inch bushing. No. 10. Pipe upright 12 inches long. No. 11. ½-inch railing Tee with thumbscrew; slides and rotates on No. 10. No. 12. ½-¼-inch railing Tee, with thumbscrew; slides and rotates on No. 10 of other side. No. 13. ½-inch pipes; three lengths, 9, 18 and 36 inches, fitted at one end with thumbscrew, other end screws into No. 11. No. 14. Steel rods, three lengths, 9, 18, and 36 inches, sliding into No. 13; other end threaded with ¼-inch thread and screws into No. 12. (Nos. 11, 12, 13, and 14 make a brace, connecting the side members, and can be lengthened, adjusted, and fastened in any position of side members.) No. 15. Steel rod 24 inches long; slides through 10, 4, and 7; upper end fastened to No. 17. No. 16. Male thread of iron bench vise screw. No. 17. Female member of iron bench vise screw, fastened to No. 15. No. 18. Swivel face plate to which foot is fastened by means of leather cuff, No. 24, or bandages. No. 19. Drop forged crank handle, 4-inch size. (Same object can be accomplished cheaper with an L-shaped steel rod 4 inches long inserted into hole bored through end of No. 16.) No. 20. Thumbscrew for fastening extension rods. No. 21. Bench or box for shoulders and head. No. 22. Sacral rest padded for comfort. No. 24. Leather cuffs fitted with harness bolt snaps, fastening ankle to No. 18.

It will be seen from the above that outside of the special table clamps (which can be obtained at a cost of $5 per set), the entire apparatus is made of stock parts, none of which cost over 25 cents, and few of which have to be greatly altered or machined. The plans of the side members are identical, excepting that one side carries No. 11 and pipes No. 13, while the other has No. 12 and rods No. 14. This combination makes a very firm brace and prevents all wobbling. Nos. 13 and 14 are made in three lengths, so that the apparatus may be braced even when the side members are separated by a distance of six feet. By oiling all threads the apparatus may at any time be unscrewed and packed into an ordinary 36-inch telescope suit case; its weight is about 25 pounds. It is capable of many modifications and uses, and of unlimited improvement. The author would welcome any suggestions to increase the simplicity and usefulness of this simple and cheap extension apparatus.

SUCTION DRAINAGE—A NEW FORM OF AIR-PUMP WHICH WILL SIPHON.

By Nathan G. Bozeman, M.D., Ph.B.,
New York.

It is a well-known fact that water which divides in falling from a reservoir down a narrow tube carries air along with it; if there are apertures in the side through which air can enter this is also carried along.

A device to divide the flow from an irrigator, and one aperture, a long branch judiciously made in a vertical tube, will accomplish the same thing, and fresh blood, pus, and secretions of the body coming in contact with this will in addition be carried away. I first applied and published,* in 1889, this principle of continuous suction for drainage, and the instrument by which it is done is unique and original with me. In my experience in draining vesico-vaginal fistulas and operating when suction replaced the swab for removing blood, and evacuating sinuses and pus cavities, it has been satisfactory. It is my desire to bring it again before the profession, omitting the irrigating features, because there has been some interest manifested in it of late.

The glass reservoir of any capacity is a bottle by means of which a constant flow of water is obtained, the velocity depending upon the vertical distance between the lower end of the open tube *T*, one-half an inch or more, and the level of the aperture *a* (diameter 0.0649 inches)† in the side; when this tube, which passes through a stopper, is pushed down below the level the flow ceases. The bottle being filled with water and the stopper introduced, the glass tube is then pulled up to the desired position, flow begins into the vertical tube *B*, filling it with water above the diaphragm at *b*, in which there

*"A New System of Continuous Irrigation and Drainage," *New York Medical Journal*, June, 1889. "A Self-Exhausting Irrigating Catheter," *The Medical News*, March 22, 1890. "An Air and Water Irrigator and Drain for Prolonged Douching in Deep Cavities," *New York Medical Journal*, May 27, 1893. "Recto-Abdominal Fistula Following Laparotomy; Treated by Improved Double-Current Irrigation," Medical Record, August 22, 1891.

†This orifice being a small circle in thin-walled vessel, the quantity of efflux can be computed.

is a pinhole puncture, diameter 0.0325 inches; this column of water, eight inches or more, is always maintained between *a* and *b*, and the pressure of it forces fluid drop by drop into the pump—three closely coiled glass tubes, connected one under the other, vertically suspended, and a pure rubber tube between 4 and 5 mm. lumen, the limits of capillarity (Jurin's law), 3/16 of an inch caliber. These coils fill, and when in unstable equilibrium suddenly discharge small columns of water which have a rapid downward motion, the whole tube is filled with cylinders of air and water, the exhaust takes place through the orifice in the side.

The capacity of the pump to rarefy air depends

Dr. Nathan G. Bozeman's Suction Pump.

upon the minimum quantity of water used, and when the vertical outflow tube is long enough it produces a fairly complete vacuum; the water then is used up quicker and more is supplied by slight increase of the pressure at *a*, also the column of water between *a* and *b* by means of a longer tube.

A convenient portable form is a bottle fitted out inexpensively by George Tiemann & Co., holding one pint, which is held in the hand five feet from the floor; it will suck up fluid the height of two and a half feet in twenty seconds and maintain that degree of exhaustion for fifteen minutes, until all the water has run out at the rate of one ounce per minute. Connections are made with the orifice of the pump according as one wishes to aspirate directly, and also siphon, or indirectly into a receiver.

67 West Forty-ninth Street.

Medical Items.

The Lungs in Cardiopathies of Children.—Hutinel says that the pulmonary symptoms to be observed in children accompanying cardiac disease differ markedly from those of the adult. If we get edema it varies in location and appearance from the adult; if there is congestion it is not located as in the adult. One will get very loud murmurs in the child, but rarely arrhythmia. In spite of the gravity of the heart symptoms the lung is generally immune. There is rarely edema of the lungs, or serosanguineous expectoration. Hydrothorax from blood stasis is infrequent. Râles are less marked. The difference of affections often lead to errors of diagnosis. The signs may appear to indicate pleurisy, bronchopneumonia, or tuberculosis when neither of these is present. The lymphatics of the pleura and pericardium are largely connected and affections of one serous membrane are easily propagated from the other. The thorax of the child is small in proportion to that of the adult, and when the heart is enlarged it presses on the middle portion of the lungs and causes it to become compressed, the circulation to be interfered with, and atalectasis to occur. This condition simulates the dullness and bronchial breathing of tuberculosis.—*La Presse Médicale.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended April 7, 1911.

SOME PRESENT DAY HEALTH ACTIVITIES.*

BY WALTER WYMAN, M.D.,

WASHINGTON, D. C.

SURGEON-GENERAL U. S. PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

THE basic principle of the twentieth century is the achievement of the maximum result with the minimum expenditure of human energy—the utilization of the forces of nature and the conservation of the powers of man. There is no department in the endeavors of the race which has not been permeated by this guiding thought—no recent undertaking of mankind which does not rest upon the fundamental idea of the liberation of the human species from the drudgeries of life.

Other centuries have witnessed a similar reaching out after safety and comfort, but heretofore the movement has been groping, discoveries have been largely accidental, and the result of observation rather than the product of accurately aimed research work. With the development of intensive methods of investigation and inductive reasoning, all the details of a problem are submitted to careful analysis and the element of chance subducted. Is an engine to be built or an edifice erected, the structural materials are tested by stress and strain and torque; the industrial laboratories of the shop, the forge, and the drafting-room are put in requisition, each approaching the question from its own particular angle. Similarly, the report of each deals with one specific portion of the inquiry, and when correlated by the engineer, the facts obtained by such a study become the foundation upon which the building rests or the stability upon which the engine depends and in the final analysis react to the husbanding of human strength.

Every aim and purpose of the world to-day springs from the desire to replace the bondage of the past with the mental freedom of the present. The waters of the earth have been harnessed to heat and light the home of man, and bear his burdens and to be his handicraftsman; the mountains have been robbed of their rich stores to create engines and ships and the power to drive them; time and space have been set at naught by the use of ethereal waves, and even the air itself conquered to become the great highway for mankind. Sunlight is driving engines; the wind which once but served to ripple the farmers' ripening grain now generates the power which propels the mower; the stubborn fields produce more and better food for man, and in every industry metal is being substituted for the brawn of humanity, and the forces of nature for those of man. Machines, reflecting the cunning ingenuity of their inventors, shear the sheep, cleanse the wool, spin the yarn, weave the cloth, cut the garment, bind the seams. The output from many factories reaches the consumer without having been touched by human hands after the raw material entered the machine, the operative acting entirely as the superior guiding force.

Unconsciously, this substitution of the mental forces of man for his physical strength in the performance of work has contributed in no small degree to the advancement of public health. Where are the aneurysms which filled so much space in yesterday's works on surgery? With the introduction of labor-saving devices the strain once borne by the heart and arteries of man was transferred to inanimate metal, and aneurysms are becoming progressively rarer. The ventilation of mines to reduce the danger of gas and dust explosions has simultaneously lessened the occurrence of miners' asthma, and the sesquisulphide process of making matches has made one of the most horrible of occupational diseases a thing of the past. To be sure, there still exist many industrial diseases which are wholly preventable, and many workmen are being needlessly maimed or killed by modern machinery. This is in part due to ignorance, both on the part of the operative and the operator, and will be remedied when both come to the realization of the commercial value of human life. The bringing about of such a realization is one of the most important labors of the health activities of the present day.

But it is not only in the workshop and the mill that labor-saving devices are acting indirectly for the improvement of hygienic conditions. The principle of the conservation of human energy has entered the home as well, and many of the housewifely tasks are now performed by machines; the horrors of washday have been eliminated and the making of bread reduced to the mere turning of a crank. The automobile will in time banish tetanus from our cities and suburban rapid transit solve the housing problem, just as the linotype has abolished type-setters' palsy and the introduction of mechanical counters has saved the eyesight of many workmen.

The progress of this age is not local, national, or racial. It is universal. All the world is contributing to this forward movement, a forward movement which is in reality one of the evolutionary processes of mankind. No narrow jealousy limits the scope of the different fields of research. The interchange of ideas and ideals is international, and the student of to-day seeks facts wherever he can find them, ransacking the world's storehouse of knowledge, disregarding no science or no tongue which may aid him in his quest. The discoveries

*Read before the New York Academy of Medicine, March 16, 1911.

of a botanist[1] mold the science of eugenics; a chemist's[2] study of a disease of silkworms points the way to the study of the diseases of men; the researches of a physician[3] revolutionize the science of zoology; the labors of a physicist[4] make human flight a possibility. A Russian student of medicine[5] experiments with fleas, his results are applied to the plague campaign in America; an American electrician[6] invents a lamp of great actinic power, it is utilized in the sterilization of sewage in Paris; a young English chemist[7] makes a dye from coal tar, and a bacteriologist[8] in Berlin uses it to stain bacteria.

Part and parcel of the great scheme of things for lightening the burden of existence are the public health activities of the present day, a conservation movement of the truest sort having for its object the saving of that highest expression of energy, human life.

Beginning with simple tribal customs, made necessary by more and more artificial conditions of life, a few simple rules, half understood and cruelly applied, constituted our elemental health laws. The origin of disease being obscure, it was but natural that the remedy or the prophylactic should be equally hazy and erroneous, hence we find our ancestors importuning the gods, exorcising devils, consulting the astrolabe, and evolving fantastic chemical theories, all to the end that the plague that stalketh in the darkness of ignorance might flee before the light of knowledge. Gradually out of the mists a few dearly bought facts stood forth as beacon lights on the course to knowledge. The plague of rats was followed by the plague of men, therefore the cat, the rat-catcher, was deified; the dung-beetle, the foe of Egyptian anemia, became the sacred scareb, and the brazen serpent was lifted in the wilderness to teach the method of extracting the guinea-worm. The communicability of disease was recognized, quarantines were evolved, fumigation was practised, and fomites destroyed. Each incursion of plague or cholera acted as a fresh stimulus to preventive methods, and gradually it was seen that the problem of the preservation of the public health was a medical one; that, to quote Butler's Hudibras,

> "A wise physician, skilled our wounds to heal,
> Is more than armies to the nation's weal."

and our profession was charged with the care of the mass as well as of the individual.

The invention of the microscope, the researches of Pasteur, the discoveries of Koch, of Laveran, of Ross, of Yersin, of Reed, all blazed the trail which has led us from the smaller field of remedial measures into the limitless expanse of preventive action. No longer are the wraiths of disease combated in the darkness of fear and uncertainty, but are fearlessly met and repulsed in the broad daylight of knowledge. What was formerly considered as a visitation from God is recognized as the penalty for man's ignorance and carelessness, and, instead of waiting in the apathy of fear for the coming of frost to abate a pestilence, disease is boldly eradicated before it has an opportunity to establish a firm foothold. No longer does the leper, bell in hand, cry out, "I am unclean; I am unclean," nor is the coming of the plague announced by carters calling in the night, "Bring out your dead; bring out your dead." Segregation has banished the former and the studies of Yersin, Thompson, and Blue have drawn the fangs of the latter.

Coincident with the growth in the knowledge of disease processes was a corresponding development in the other departments of learning. We are too apt to think of medicine as having made its progress independently of the other branches of science. As has been shown, there is a correlation between all the sciences, and medicine more than all the rest is debtor to all the divisions of human understanding. The chemist discovers formaldehyde, the sanitarian employs it; a milkmaid notes the prophylactic value of cowpox, the physician utilizes the observation; a charlatan exploits mesmerism, a psychologist perfects hypnotism. We must, therefore, consider the expansion of the public health ideal, not as a thing by itself, evolved by a public spirited profession, but as one of the manifestations of the great uplift which mankind is undergoing. As a corollary it may be added that if we are to best discharge our duty as soldiers of the common good we must keep step with the great forward moving army of humanity. We must hold our place in the line, neither pressing ahead of the band nor lagging with the rear guard. And such victories as may be won must be accorded, not alone to any one corps or individual fighter, but to the army as a whole and to the great Chieftain who leads us all.

And now having passed the milestones of sanitary theology, demonology, charlatanism, and pedantry, by the signpost of the medical period, we are now entering into what may be called the medico-economic era.

We have recognized that the wardenship of the public health is a task of infinite magnitude and intricate detail, touching every angle of existence and reaching to the very core of life itself, and as our vision expands to meet the ever widening view we see that the problem is one of medical economics, that every science has some bearing on the question, and that the sanitarian must coordinate the efforts of the physician, the chemist, and the engineer, the statistician, the economist, and the administrator. Every industry, every walk of life, every environment, must be studied in all its hygienic aspects in order that we may know all the phases of the field of inquiry. Disease is protean in its etiology; sin and ignorance and greed all enter into the soil in which it grows; it is nurtured by uncharitableness and reaches its fruition in the miseries of human wretchedness. Until we are thoroughly familiar with the conditions in which disease is bred we cannot hope to successfully cope with it, therefore the work which lies immediately before us is the study of such conditions from the viewpoint of medical economics.

As we study we must teach, because, after all, the great field of sanitary usefulness lies in the education of the general public. Such instruction must be given wisely and by competent teachers, half-truths being almost as dangerous as lies, and we would do well to emulate Chaucer's poor parson of the town.

> "This noble ensample unto his sheep he gaf,
> That ferst he wroughte and after that he taughte."

Education will banish those foci of disease and crime, the city slums; temperance and venereal prophylaxis will empty our insane asylums, and the

disease of destitution will be eradicated by the dissemination of knowledge; the lethal common drinking cup and the deadly roller towel, the open privy and the fly-breeding stable will become as obsolete as those other instruments of human destruction, the glaive, the mace, and the cross-bow.

As an expression of the expansion of the conservation ideal, we have the birth and gradual growth of the national public health agencies. Beginning with the simple tribal sanitary observances, which became law, the movement was at first local. Then, expanding, it comprehended the shire, the duchy, the principality, the kingdom, and finally the empire. Nothing was created *de novo*, springing, as it were, from the forehead of Minerva fully formed, but the structure has been laboriously raised stone by stone, custom by custom, law by law, and the rate of progress has been in direct proportion to the education of the general public regarding the prophylaxis of disease. This is an important fact which many truly altruistic members of our profession have overlooked. No matter what the form of government may be, in the final analysis it is the people who decide what health laws they will obey and what they will not, and any great movement in such matters comes from them.

The health movement is one which can be hurried only by education, and which is hampered by the impatience of idealism. In the words of Senator Knox, now Secretary of State, "Sometimes a portion of the people, strong by reason of their numbers, or by reason of their zeal and activity, and interested in the accomplishment of laudable aims, become impatient and restive under the checks and balances and boundaries which control and harmonize our system, and may, therefore, oppose what they want through the methods they propose."

Each of the great nations of the world has gone about the erection of its public health machinery in its own way, has by a process of evolution and elimination produced that which was for the time being best suited to its own particular needs, always with the realization that the ideal is not necessarily the practical and that what is best to-day may be supplanted by a better to-morrow. In each case geographic conditions, temperamental characteristics, and form of government had to be taken into consideration, and each nation has evolved a system to meet its own requirements. It is, therefore, difficult for us to comprehend fully the public health organizations of other countries, and it is equally impossible for us to make an accurate comparison between systems which, though they may have the same general aim, differ in their application. Each country may learn from the other, may borrow methods and modify them to suit existing conditions, but to transplant them without proper pruning is to invite speedy wilting. It is certain that we should have a thorough knowledge of what we have at home before we attempt to exchange it for what we know less about abroad.

There are, however, a few broad general divisions upon which a rough basis of comparison may be made, and it may be interesting to consider under these broad heads the national public health systems of England, France, Germany, and the United States. It should be borne in mind that the comparisons are only approximate, that there are modifications of custom and environmental conditions which require almost a lifetime of practical observation for complete comprehension, and that it is not necessarily the nation with the most elaborate laws on its statute books which has the most efficient public health system.

At the outset we are struck with the fact that none of the countries under consideration has a national department presided over by a minister and devoting its entire attention to the care of the public health. In England, the central health authority is the Local Government Board, which corresponds roughly to the United States Department of the Interior, and has, in addition, certain legal and financial functions. In both France and Germany the central health organization is a bureau under the direction of the Minister of the Interior. The central health authority of the United States is the Public Health and Marine Hospital Service, a bureau under the Secretary of the Treasury. In none of these countries is the minister necessarily a physician, and in all of them the brunt of the execution of most of the health laws falls on the local authorities. The central organization is largely clothed with advisory powers, but certain executive functions, such as the administration of the quarantine and the control of epidemics which interfere with commerce between the States, are delegated to it in the United States.

The prime requisite to advice is knowledge, hence scientific research is one of the important functions of the central health body. England and France each maintain a small laboratory for such purposes, the former depending upon the employment of experts for such investigations. Germany, on the contrary, maintains two large, well-equipped laboratories for scientific research. This is the strong point of Germany's health administration. The Hygienic Laboratory of the Public Health and Marine Hospital Service, in its organization, compares favorably with the laboratory maintained by Germany, although, at present, it is not so large and extensive in its operations. Its organization is such that, with natural development, it should equal in all respects the laboratories of any other country. It is much superior to those of England and France. It should be borne in mind that these remarks apply only to the official laboratories of the general governments in question.

In England there are two systems for the collection of vital statistics, one by the registrars who establish their districts on the Poor Laws Union Unit, the other by the local medical officers of health on the sanitary area unit. It may be noted in passing that these units do not necessarily coincide. It is but natural that the modern science of vital statistics, which had its birth in England, should there reach a high degree of efficiency, and as the basis of intelligent, accurate state action in the field of preventive medicine, they form one of the strongest points in England's public health system. In France the collection of vital statistics is dependent on voluntary registration, there being no general law for the collection of vital statistics and a lack of uniformity in the local laws relating thereto. There is, however, a general law relative to the reporting of contagious diseases. The national vital statistics of Germany, while full and complete, are not collected under any general law, and their contribution to the general government is voluntary on the part of the States. In the United States such morbidity and sanitary statistics as are available are collected under the acts of February 15, 1893, and July 1, 1902, by the Public Health and Marine Hospital Service, with the voluntary cooperation of the several States and Territories. These statistics are

published weekly, together with other sanitary information of similar character collected abroad. Through an understanding, and in order to avoid duplication of work, mortality statistics are collected by the Bureau of the Census and published annually. Such statistics relate only to the registration area, however, which comprises 18 States and 54 cities in other States. It is thus evident that neither our mortality nor morbidity statistics are complete, and in some States the laws relating to these matters are very defective. Progress is being made, however, and there is indication of increasing uniformity of legislation relating to vital statistics.

The central health authorities of England and France issue annual reports, regulations, and sanitary statistics. In addition, England prepares a weekly confidential report of contagious diseases for the use of its local medical officers of health. The publications of the German Imperial Board of Health are very excellent and include many valuable scientific memoirs. In the United States the Public Health and Marine Hospital Service issues a weekly publication, as noted above. In addition to articles dealing with sanitary problems of current interest, this service also issues valuable research bulletins dealing with certain phases of investigative work, the bulletins of the Yellow Fever Institute, and the annual report of the service. There is one important difference between the American bulletins and those issued abroad, *i.e.* ours are issued free of cost, while in foreign countries a small charge is usually made. This naturally depletes our appropriation more rapidly than if there was some income from the publications, and with more money our national public health service could accomplish much more in this regard.

In England the maritime quarantine is almost entirely a local matter, administered by the port sanitary authorities. The customs officers board incoming vessels, and upon the discovery of disease notify the sanitary authorities of the port, who then visit the vessel.

France has a national quarantine system administered by the Department of the Interior. The republic is divided into seven maritime districts under the Bureau of "Prophylaxie et Epidemies." Each of the districts, or "circonscriptions," is in charge of a "Directeur de la Santé." His district is divided into departments, each of which is under an "agent principal." The system would appear to American eyes as somewhat cumbersome, although efficient.

Germany has no national quarantine system. Only four of her twenty-six states are affected by maritime quarantine, and in each of these the organization and administration of the quarantine is a local matter. For purposes of uniformity, the quarantine services of these four states have organized themselves into a "bund," or union.

In the United States the quarantine functions of the general government are discharged by the Public Health and Marine Hospital Service. The minimum requirements at all ports, whether guarded by a national, State or local quarantine, are set by regulations promulgated by the Secretary of the Treasury under the authority of the act of February 15, 1893.

As an additional precaution the United States is kept informed of foreign health conditions through its officers stationed abroad, and it is in this way that the Public Health and Marine Hospital Service has been able to carefully follow the course of the present pandemics of cholera and plague, which now threaten us on both the Atlantic and Pacific coasts.

Beginning in 1893-4 in the Yunnam province of China, plague has spread to every continent on the globe. Its appearance on our Western coast was a serious menace, but fortunately, as a result of the combined efforts of the Federal and State authorities, it is now under control, though the infection still persists among ground squirrels in rural communities. A new danger has arisen, however, with the recent reappearance of plague in pneumonic form in North China and Manchuria, on the west of us, and in the County of Suffolk, England, on the east of us.

Within the last year cholera, which, in recent years, has confined itself to Japan, China, the Philippines, and Russia, spread into Germany, Austria-Hungary, and Italy, and is now as close to us as the Madeira Islands, about seven days by sea from New York. Cases have occurred on vessels en route to New York, and also at the quarantine station of the same port, as well as at Quebec, Canada, and at some of the South American ports. Cholera also threatens us from the west, having recently made its appearance in Honolulu, five or six days from San Francisco.

We are thus menaced on all sides by plague in the bodies of rodents, and cholera in the persons of chronic spirillum carriers. The utmost vigilance is being exercised to prevent the embarkation of these diseases for American ports, and to apprehend them should they appear on our frontiers. Never more than at the present time have the necessity and usefulness of our quarantine system been more apparent. During the fiscal year ended June 30, 1910, 7,271 vessels were inspected, and 407,569 persons inspected, at the national quarantine stations of the United States, while at the insular quarantines (the Philippines, Hawaii, the Canal Zone, and Porto Rico) 3,072 vessels and 421,953 persons were inspected.

There is no better example of the evolutionary processes of public health machinery than in the history of the growth of the national quarantine system of the United States. During the pre-Revolutionary period the Colonies had their own quarantine regulations, and from the formation of the Union until 1803 this function was relegated to the States, and by them to the counties, or municipalities, as the case might be. All national quarantine legislation up to 1893 specifically provided that the measures enacted were in the aid of State and local authorities. The leaving of the quarantine power to the local governments was an invitation to a lack of uniformity which was a serious burden on commerce. This fact had long been recognized—in fact the matter was taken up by the First Congress—but a definite change was not made until 1893. When it came it was but natural that the United States Marine Hospital Service should be chosen by the legislators to discharge this important function. Having maintained the Marine Hospitals for nearly a hundred years, its officers had become familiar with exotic diseases and the administrative details of government work and from this small beginning sprang the great system which now guards 5,450 miles of coast line of the continental United States, to say nothing of the quarantines on the Canal Zone in Porto Rico, Hawaii, and the Philippine Islands.

Going a step further, having learned how to sanitate ships, it was but natural that the control of

disease on land should follow, and this duty was imposed by law. As a further step, the Congress which has just closed has recognized as public health hospitals of the truest sort the marine hospitals by including in the law providing for their maintenance the following clause:

> "* * * there may be admitted into said hospitals, for study, persons with infectious or other diseases affecting the public health, and not to exceed ten cases in any one hospital at one time."

This will afford an opportunity to study at close range pellagra, amebiasis, anterior poliomyelitis, and many other diseases whose etiology is not entirely clear at the present time. Already arrangements are being made to utilize the opportunities thus offered, and investigations as to the coexistence of amebiasis and uncinariasis will be undertaken at the U. S. Marine Hospital at Wilmington, N. C., at an early date.

In England, France, Germany, and the United States questions of local sanitation and hygiene are largely left to the local authorities, the central health authorities discharging a more purely advisory function. The prevention of disease had its birth in the home and it is there that we must begin to-day any movement for the betterment of the race. Hence, all administrative measures of the public health have as their foundation the household, and their execution naturally rests upon the local health officer. He is the vital point in all public health systems, the base upon which all the administrative fabric rests. He is at once the strength and the weakness of the entire system, and the degree of efficiency of the whole machine is determined by him. We hear a great deal about the superiority of foreign health systems. If it exists it is in the superior qualifications of its local health officers. English health laws require that health officers shall be trained sanitarians with a diploma of public health which can be obtained only after special study and training. We have in this country only a few universities in which such training can be obtained and until the salaries paid to state and municipal health officers are better there will be little incentive to take such training. It is but natural that such conditions should obtain in this country. American civilization is of comparatively recent establishment, and we have been too busy exploiting our national wealth to pay much attention to our national health. Man as a mere hewer of wood and drawer of water was a relatively cheap animal, but as the director of the inanimate forces of nature he has acquired a greatly increased value. When the price of men was low no one took great pains to study the saving of them *en masse*, and it is only recently that the enhanced appraisement of humanity has created a demand for highly trained local sanitary officials. This demand, like all others, will be satisfied in time.

In this connection it is interesting to note the experience of the British authorities in their recent plague outbreak. The following quotation from an article by a special correspondent on the subject of "The Rat Plague in East Anglia" appeared in the London *Times* for December 22, 1910:

"The case is one for direct government intervention. The danger, so far as it exists at all, is national, and the money to be expended should be furnished by the nation. England is the only country in the world which has not made an outbreak of plague a national question. It is unreasonable to expect small rural authorities, or even important boroughs, to pay for and to direct an elaborate technical inquiry, extending over many administrative areas, into a question which really affects the whole country. Many small communities have already been hard hit because they can no longer find a ready sale for their produce. They have spent considerable sums on preventive measures, which are more or less useless until the precise extent of the mischief has been ascertained. The local authorities on the whole have done exceedingly well. Various medical officers of health have given much of their time to the inquiry, but they necessarily lack experience of plague, and they have their normal duties to perform. The able inspectors of the Local Government Board have been extremely energetic, but they can only advise and have no spending power. The system of public health administration in England was not planned for such an emergency. We are dealing with new conditions, and new methods must be devised. Unless the Cabinet intervenes, there is actually no machinery in England by which large expenditures can be ordered upon the kind of investigation suggested. The duty of spending money upon measures of health is in the hands of a multitude of local authorities. The system works well as a rule, but it will not serve for the present instance. The organization of the local authorities should be utilized, but control and expenditure should be undertaken by the government."

In the United States there is much local law bearing on the subject of hygiene and sanitation, and there is also national authority for the prevention of the spread of infectious and contagious diseases, but there is a curious kink in American character which considers that when a law is enacted a condition of fact is altered, and unfortunately many good local health laws are not enforced. This is as the mass of the citizenship desire it, because no matter how many laws the legislative body may enact, or how many officers it may appoint to compel their obedience, when all is said and done it is the body politic which enforces them, and no law really achieves its purpose unless the people earnestly desire to obey it. But gradually there is an increasing interest in these matters, and good paving, good drainage, efficient sewerage, light and air for all, and a safe water supply are becoming issues in municipal politics. This spreading attention to matters of sanitation is also manifesting itself in civic betterment movements, church and social service, social centers, public play and social education, and in careful municipal study of city planning. School children with defective sight and hearing are no longer classed as stupid, but are given proper treatment for the ailments which are retarding them in their studies; we see open-air schools for tuberculous children, and special clinics for those afflicted with nose and throat affections; mouth hygiene is given special attention, and many a wayward, stupid child transformed into a tractable and studious pupil by the treatment or removal of its carious teeth. This is not only a means of immediate relief, but also a part of the propaganda of the spreading of knowledge regarding personal hygiene.

Much good along these lines may be accomplished by the labor unions, which are nearer to the great voting public than any other of the organized bodies in our cities. Similarly the Y. M. C. A. and kindred organizations might do a great work by the offering of free courses of lectures on popular sanitary subjects.

The English laws regarding water pollution are quite extensive, but their enforcement is largely delegated to the local authorities, the Local Government Board seldom entering into the question except in relation to finance or taxes. In France and in Germany there are no general laws dealing with the subject of water pollution, this important subject being regulated in both instances by local laws. The United States has no general law relating to the subject from a public health standpoint, and at present this very important function devolves upon the State and local health authorities. The Public Health and Marine Hospital Service has, however, taken up the matter of the pollution of the Great Lakes, and at the present time an investigation of this subject is being made from the Hygienic Laboratory.

The English local medical officers of health are largely responsible for the examination of milk and other foods, but the Board of Agriculture makes regulations regarding the food value and purity of milk, cream, butter, and cheese. In France the standards for milk and other foods are a matter of general law administered by the Minister of Agriculture, while in Germany there are comprehensive imperial laws on the subject. These are enforced by the local authorities. The Pure Food and Drugs law in the United States is administered by the Bureau of Chemistry, located in the Department of Agriculture. This is a commercial law relating to mislabeling and applies only to interstate commerce. Many of the States have rigid pure food laws, but these, of course, are only active within their borders.

This discussion of the present day health activities has not endeavored to deal with details, but with the broad underlying principles of which these activities are a result. The army of mankind is on the march, decrepit age and vigorous life, and blooming youth and helpless infancy, pushing forward toward the ever-receding goal of perfect understanding, some on crutches, some in the pride of strength and health, some in the full blush of promise, and some at the mere dawn of life; the laggards and the weaklings fall by the wayside; the craven and unknightly are dropped from the rolls: but to the loyal and the steadfast, the faithful and unswerving, comes the victory of duty honestly performed, the benediction of having made the world a little better, safer place to dwell in. No blaring, tawdry triumph waits the sanitarian returning from the conquest of disease. For him a real triumph is given in the depths of his own heart, far better than most fulsome praise and richer than rewards of princes. Ours is the great privilege of living in an age unequaled in the number and character of these victories; one by one the noiseless messengers of death and pain have been vanquished, and, though the battle is far from won, we have the inspiration of a supreme confidence in the successful outcome of the war for the health of the nation and the safety of the home.

Poliomyelitis and Rabies.—Landsteiner and Levaditi note the striking analogy between these diseases. The propagation of the virus along the nerve trunks, its affinity for the nerve centers, its behavior with regard to desiccation and the action of glycerine, its filterability through porcelain, are facts common to both diseases. But monkeys that have been rendered immune to poliomyelitis are nevertheless susceptible to rabies.—*Annales de l'Institut Pasteur.*

ON THE TREATMENT OF EPITHELIOMA, LUPUS, ETC., WITH THORIUM PASTE.*

NEW YORK,

PHYSICIAN TO THE NEW YORK SKIN AND CANCER HOSPITAL, CONSULTING PHYSICIAN TO THE NEW YORK HOSPITAL, ETC.

For a number of years there have been treated in several clinics of Europe, Paris, Vienna, and London cases of epithelioma, lupus, etc., with thorium, one of the radioactive substances, and the reports which have come to hand in regard to it are most satisfactory. Accordingly early in September I offered the facilities of the New York Skin and Cancer Hospital to Dr. C. B. Semerak, who had been using it abroad, for the trial of a certain combination of it on patients here. The results which have been observed there and also on some private patients have been so eminently gratifying as to warrant a presentation of them. The exact preparation which we have employed is not yet on the market, and thus far Dr. Semerak has prepared it himself and has attended personally to its application at the hospital almost daily and also lately in my office.

This new preparation is called thorium paste and is composed of thorium, protoxide and sulphate of lead, sulphuric acid, and a small amount of hydrochloric acid. It is in the form of a semiliquid paste, which is applied to the affected part with a camel's hair brush after thorough mixing. It forms a thin, white pellicle, which remains adherent for a week, ten days, or perhaps longer, and when it falls off or is gently removed it is evident that there has been an effect on the diseased part, which, of course, varies according to the nature and stage of the lesion.

The action of the paste is moderately destructive on diseased tissue, but the amount of destruction can be regulated at the will of the operator, according to the degree of dilution employed; it has also the peculiar property of modifying cell growth and accelerating the proliferation of healthy cells. It is interesting to watch the changes taking place after each thin crust has fallen, which are, of course, different in different conditions of disease.

In epithelioma the first application will cut down the disease materially, and sometimes leave a raw surface; sometimes it will be dry. With renewed applications healthy tissue replaces the deranged epithelial cells, all induration is removed, and the surface becomes normal, with very little if any scar, much as in the use of the *x*-ray.

In lupus vulgaris, as the skin exfoliates after the application, there is seen less of the lupus tissue, and after a few applications the brownish deposits cease to be visible with the diascope, and a smooth, supple cicatrix results.

In lupus erythematosus the skin simply regains its normal condition more and more after each application, and the disease may disappear without a scar. In some cases of nævus pigmentosus the lesion has melted away and an almost normal skin of good color has replaced the diseased tissue after a few applications of the thorium paste.

It would be too early to pronounce definitely in regard to the full value of this method of treatment were it not for the unqualified testimony in writing of physicians of standing in Europe who

* Read and cases presented before the New York Academy of Medicine, Dermatological Section, February 7, 1911.

have observed its use during the past seven years, and for the collection of photographs which Dr. Semerak has brought with him. The testimony is that these cases have remained well after treatment, and after watching the progress of the cases treated here, and seeing some of them repeatedly after treatment has been suspended, I am convinced that we have in this paste a valuable addition to our means of combating a number of cutaneous conditions which often prove very rebellious.

It is difficult to give briefly any adequate statement as to exactly the cases to which the thorium paste is applicable, or directions as to its employment in all possible conditions. We have applied it satisfactorily to some cases of epithelioma of considerable size, also to lupus of large extent, also to small new lesions. Commonly it can be painted on in full strength, but in some extensive cases it is well to begin with repeated compresses of one or two per cent. or more in water. As the lesion shrinks under these, single points can be painted with the pure paste. In some instances an ointment, ten per cent. in lanolin, serves well to melt away the diseased tissue.

In some cases of recurrent epithelioma after operations the thorium paste has been of remarkable service. In one patient, a woman about 40, there was a raw patch one inch by two inches at the root of the neck, in the center of much scarring from a former operation. This entirely healed under a few applications of the diluted thorium paste. Also in one or two cases where there were postoperative epithelial tumors, they melted away, leaving healthy skin.

From my present experience in some dozens of cases and from a study of a large number of reports of cases cured in Europe, furnished by Dr. Semerak, I am still unable to state just the conditions in which the thorium paste is *not* applicable, for thus far the results observed have all been satisfactory. We have, of course, lost sight of some patients, as is inevitable in public practice. In the majority of the cases of epithelioma the lesions have been small and comparatively recent, but some others have been quite extensive and long standing. The lupus vulgaris cases have been mostly of long duration, often very extensive, and which had been previously submitted to the most varied treatment. Some more recent, smaller lesions have disappeared with a few applications; in some of the older cases it is far too early to judge from them, except in the manifest improvement of certain portions. But the written reports and pictures of cases treated in the Hôpital St. Louis, Paris, show certainly that this remedy can remove the lesion perfectly. The same is true in regard to lupus erythematosus. There are also written reports in regard to the satisfactory treatment of other skin lesions, but investigation in regard to these must be deferred to a later date, as my observations relate mainly to the diseases mentioned.

Little can now be said in regard to the mode of action of the remedy under consideration, except that the close application of the slightly radioactive thorium seems to have a modifying action on cell life, similar to that from radium and the *x*-ray. I do not think that the other ingredients mentioned in the paste can have much share in the recuperative process, although they have some caustic action in reducing the diseased tissue. It may be a little interesting to mention the very recent notices which have appeared in the secular press regarding mesothorium, extracted from thorium, which Prof. Rutherford says is quite as good for medical purposes as radium and much cheaper. Thorium is a common commercial product and the material from which it is extracted is abundant in many countries.

In conclusion, I regard the thorium paste as beyond the stage of experimentation, as it has been in use successfully for seven years in the Hôpital St. Louis, Paris, and in various dermatological clinics abroad. A large number of cured cases were shown at the Medical Congress held in Lemberg in July, 1907; all had been previously treated with various caustics, *x*-rays, etc., and one lupus patient had had 1,400 séances of Finsen light. While I would not advise it to the exclusion of all other methods of treatment, I am convinced that in it we have a valuable addition to our means of combating some of the most rebellious forms of disease which may occur in the skin.

A few illustrative cases out of many may be briefly reported. I may add that these cases were all carefully watched during the progress of treatment by very many members of the clinical staff of the New York Skin and Cancer Hospital and many of them were shown, during treatment, at my clinical lectures at the hospital.

Case I.—On November 2, 1910, we saw Rebecca M., 42 years of age, born in Russia. Diagnosis, epithelioma on right shoulder, large ulcerated lesion. The patient was operated on two years ago for the removal of a cyst. Several months later recurrence, and in April, 1910, another operation was necessary. Shortly after this second surgical intervention the scar began to become ulcerated, the borders were much inflamed, elevated, and hard. There was a disagreeable odor. Several caustic remedies were applied with no result.

The thorium treatment began November 2, 1910. A 20 per cent. aqueous solution of thorium paste was applied on the hard edges, and the patient was directed to apply wet dressings every night of 1 per cent. solution of thorium paste in water. November 11 the crust on the borders which was formed by the thorium paste fell off without very much change in the general appearance, but the odor was not so strong. Second application of 20 per cent. solution on borders and wet dressings continued.

November 18, crust fallen off on edges. Lesion looks less inflamed and healthy granulations disseminated all over the surface. November 23, nearly all ulceration had disappeared, no odor, lesion is smaller. November 25, lesion healing rapidly and closing on both sides, but still one small ulcerated point at one end. November 28, washed the whole lesion with a 20 per cent. aqueous solution, the wet dressings still being continued every night. December 1, the whole lesion entirely healed, the scar presents a normal skin, and the borders are soft. The patient is discharged.

Case II.—Magdalene D., September 14, 1910, age 66 years. Diagnosis, epithelioma on region of right temple, hard and protruding, the size of a hazel-nut, duration three years. February 5, 1908, she was submitted to *x*-ray treatment for several months with no effect whatever. On September 14, 1910, the first application of pure thorium paste was made. September 16, epithelioma not protruding, it is even with the general surface. Second application of pure thorium paste applied October 15. The crust was torn off by accident, the lesion was bleeding, washed it with a 10 per cent. aqueous

thorium paste solution to stop the bleeding and heal up the sore. When the patient presented herself at the hospital, November 30, the lesion was entirely healed; there was only a very little inflammatory reaction. She was directed to rub it gently every night with lanolin, and on December 9 the scar was normal, the skin movable, without any inflammation. The patient was discharged.

Case III.—Mrs. Frances T., age 74 years, born in Ireland. Diagnosis, epithelioma on tip of right ear. The lesion was moist and crusted and the whole upper part of the ear rigid and very painful. The patient had been treated previously for two years in different dispensaries with silver nitrate, nitric acid, etc., and for several months she had received the *x*-ray treatment with little effect. On September 20, 1910, pure thorium paste was applied. The crust fell off on October 14 and there was great improvement, but the ear was still stiff, rigid, and painful, and the place where the lesion originated was bleeding slightly. A 10 per cent. mixture of thorium paste in lanolin was given to her, with directions to rub it on every night. On December 21 all the lesion was healed entirely, except the original point. The skin was smooth and the ear was normally elastic again. The patient suffered no more. Pure paste was then applied to the remaining hard place; this formed a very thick and hard crust, which fell off January 16, 1911, and there was hardly a visible scar left. The entire lesion was healed. The patient is still under observation.

Case IV.—Ida I., 51 years of age, born in Finland. Diagnosis, epithelioma on bridge of nose. Exuberant and deep-seated lesion with inflammatory borders, duration seven months. On November 18, 1910, pure thorium paste was applied. November 29, the crust fell off, leaving an excavated and slightly ulcerated scar. Borders still inflamed. Second application of the thorium paste. December 11, crust fell off, no ulceration, but still inflamed. A 10 per cent. mixture of thorium paste in lanolin was given to the patient to apply on the lesion every night, and on January 16 the lesion was healthy in appearance, there was no inflammation, and the excavation was filled normally. The patient was discharged.

Case V.—Mr. C. K., seen December 4, 1910, age 93 years. Born in the United States. Occupation, engineer. Diagnosis, epithelioma on right side of nose. Duration, six years. Epithelioma protuberant on upper side of nose; at the lower end the ulceration reached deep into the cartilage. It had elevated and hard edges. On December 4, 1910, the first application of 50 per cent. aqueous thorium paste solution was applied on the edges and the protuberance. January 3, 1911, the edges and protuberance disappeared, but the entire lesion was ulcerated and there was a good deal of inflammation. The patient was given a 3 per cent. aqueous solution and he was directed to wet the dressings with this solution every night. January 27 the lesion was not ulcerated, there was no inflammation, the parts that were ulcerated were filled and the whole lesion was covered with a healthy skin. February 15 the patient was perfectly well and the nose was normal.

Case VI.—Wm. H. C., age 83 years. Diagnosis, rodent ulcer. About the middle of the left cheek there is an ulcer extending from the middle of the cheek to the side of the nose where it joins an ulcer running from margin of nostril up in fold between the nose and cheek to within one-quarter inch of top of nose. Ulcer has clean cut walls, fairly deep. Very little induration at edges and in base, base covered with small amount of pus. Some parts have crustings. In neighborhood of ulcer on cheek there are several small, congested masses, one-quarter inch in diameter, which have appeared recently and which are becoming very active. Process began about ten years ago, but had been active only about eight months, the ulceration extending rapidly in all directions and becoming deeper. On cheek the ulceration extends well down into the subcutaneous connective tissue, and on nose the cartilage has become involved and in one place the ulceration has extended nearly through it. October 26, 1910, thorium paste, pure, applied to portion on cheek. October 30, 1910, thorium paste applied to portion on nose. November 2, 1910, thorium paste, pure, applied to whole diseased surface. November 7, thorium paste applied to edges, general condition much improved, dry crust forming over the entire ulcer. November 11, injured nose and the crust over part of ulcer involving it had become loosened and had fallen off. Paste applied again. November 16, crust had fallen off of nose and partly off of ulcer on the cheek. Nose better and the cheek very much improved. Paste applied again. November 21, condition about the same, crust still on nose and new one on cheek. Paste applied on sulcus of crust on nose and lower end of ulcer on nose. November 25, condition seems much better. Paste applied again as on November 21. December 2, condition seems improved. December 7, crust off of nose and cheek, entirely healed, scar scarcely noticeable. No puckering or infiltration.

Case VII.—George K., a schoolboy, age 13 years, was born in the United States. Diagnosis, lupus vulgaris on right cheek. Duration since earliest childhood. Two circular lesions each three-quarters of an inch in diameter. Previous treatments, carbon dioxide (snow), caustics, and *x*-ray. No improvement. On October 17 pure thorium paste was applied. On October 29 crust fell off and lesion looked paler. Second application of thorium paste made November 13, one spot nearly well, leaving only three little disseminated tubercules. Third application of thorium paste made. On November 25 both lesions looked normal and there was only a very little inflammation. The patient was told to come back in a week. He did not return until December 30, when both lesions were very much inflamed and swollen and there were a large number of hard tubercules. After cross-examination, the boy admitted that he had been treated since by his family doctor. Thorium paste was applied again January 11, both lesions improved. January 30, improvement continued, both lesions are paler. February 14, both lesions well, no inflammation, and no tubercules visible.

Case VIII.—Mrs. A., age 35, born in the United States. Diagnosis, lupus erythematosus. Duration, three years. Typical butterfly lesion on nose and cheeks. Previous treatments: For one year the patient was treated with *x*-rays and carbon dioxide, etc., with good results, but immediate and extensive recurrence one and one-half years ago. October 29, first application of thorium paste diluted in water 50 per cent. November 13, lesion improved. The second application of 50 per cent. dilution of thorium paste. November 25, a large region in the center healed. Third application of thorium paste (pure) on the borders. December 17, the lesion was

half its original size. Fourth application of thorium paste (pure). December 29, the skin on several places had a normal appearance and there was no inflammation. Fifth application of thorium paste. January 15, 1911, the lesion on the left cheek looked perfectly healthy, though slightly lighter than the normal skin.

Case IX.—Ludwig Z., 21 years of age, born in the United States. Diagnosis, lupus erythematosus. Duration, five or six years. He had been treated for several years in different dispensaries with caustics, x-rays, etc., without any result. The lesion spread very fast until it covered all his face. The skin was hard and tight. On October 11 the thorium treatment began, a two per cent. aqueous solution was given him, and he was directed to apply dressings wet with this solution every night and keep them on until morning. January 30, there was a remarkable change, most of the face was normally white and skin soft, and there were only separately disseminated little spots which should have been treated with the thorium paste full strength, but the patient, not being able to come to New York, was directed to continue the same treatment for some time, until he was able to come to the dispensary.

Case X.—Walter B. (negro), age 15 years, born in the United States. Diagnosis, lupus erythematosus. Duration, one year. Five extensive coin-shaped lesions scattered over both cheeks, involving both ears; they were very hard and often bled. November 21, 1910, application of thorium paste (pure) was applied on the five lesions and a 10 per cent. solution of thorium paste in lanolin was given the patient to rub the ears with. On December 5 the coin-shaped lesions were paler, the ears remarkably improved and very soft. The same treatment was repeated. December 19, more improvement, the same treatment continued. December 30, one spot under the ear was entirely healed, the other spots were improving, the same treatment continued. January 11, 1911, no induration on ears, lesions healed up a great deal, there were only some little hard points disseminated. Same treatment continued and also an application of 50 per cent. aqueous solution on the hard points on the ears. February 5, three other spots that were on the cheeks were entirely cured, the same treatment was continued.

Case XI.—Margaret O'C., age one year, born in the United States. Diagnosis, nævus araneus, under left eye. Duration, two months. December 16, thorium paste was applied. On December 30 the lesion seemed to be entirely destroyed, leaving no scar at all.

Case XII.—Margaret S., age 53 years, born in Germany. Diagnosis, large verruca on left side of nose. January 9, pure thorium paste was applied. On January 28 the verruca had entirely disappeared, leaving no scar.

THE TEACHING OF SCHOOL HYGIENE.

By JAMES BURNET, M.A., M.D., M.R.C.P.E.

EDINBURGH, SCOTLAND.

LECTURER ON PRACTICAL MATERIA MEDICA AND PHARMACY; REGISTRAR, ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH, ETC.

The school hygiene movement was never so marked as it is at the present time. All over the American and European continents a service of school doctors has been inaugurated. In America, Boston was the first to initiate the movement, when in the year 1894 some fifty medical examiners were appointed to inspect the various schools in that city. Three years later New York selected nearly three times as many doctors to carry on the work of the examination of schools and scholars. At the present time the system of school inspection has extended all over America. While the greater part of the work has been entrusted to medical men specially appointed for the purpose certain portions are left to be carried out by the teachers themselves, who are asked to report upon the vision and hearing of the scholars under their charge. The question as to the advisability or otherwise of allowing laymen to discharge such an important duty is outside the scope of the present article, but we may state that we doubt very much the ultimate value of vision tests carried out by anyone but an ophthalmic surgeon or by one who has had some definite medical training.

The fact that so many medical men are now employed in examining school children at once raises the question as to the special training which these medical examiners should possess. In the first place they should have had considerable experience, either before or after graduation, in the examination of children. A certificate of such experience should be demanded of every candidate for such an important post as that of school doctor. Then, again, they should have some knowledge of diseases of the eye, ear, nose, and throat. Finally, they must have been carefully trained in the principles of school hygiene. In fact, an ideal course of instruction in school hygiene, such as we shall attempt to outline, ought to enable any medical man who has had some experience in the methods of examining children to qualify as a school doctor.

At the present moment the teaching of school hygiene is either nonexistent or at the best imperfect. It too often forms only a meagre portion of a not too perfect course of public health. This is not as it ought to be. At the very outset it should be kept in mind that hygiene must be based on physics and physiology. The earlier portion of the course on school hygiene should, therefore, embrace the principles of these subjects insofar as they relate to hygienic science. Thus, with regard to physiology the lecturer should devote some time to the consideration of the eye, ear, nose, teeth, and throat; while in respect to physics the rudiments of heat and light must at least be dealt with. It is all very well to presuppose that every student of school hygiene has already passed a satisfactory examination in physics and in physiology; but it does not by any means follow that he has retained the facts regarding these subjects with which he was at one time familiar. Hence the great necessity for making certain that he does possess a sufficient knowledge of these two branches of science before he proceeds to take up the study of school hygiene proper.

Coming to the actual teaching of the subject of school hygiene we would emphasize the fact that, as a rule, too much attention is paid to unimportant matters, while others of great and everyday value to the school doctor are passed over. The personal hygiene of the scholar should first of all be carefully dealt with under the headings of Cleanliness, Clothing, and Condition of the Teeth. Cleanliness of the skin and of the scalp should be specially emphasized and diseases due to neglect described, such as pediculosis, impetigo, and scabies. The value of school baths and lavatories, with details of their construction and management, should

be referred to. The clothing of the school child as regards its suitability, cleanliness, or otherwise might be considered at some length. The dangers of tight clothing, and of garments made of inflammable material should be indicated. The evils arising from improperly fitting boots will also call for remark. Due attention must be devoted to the teeth, and the causes of dental caries. The prevention of the latter is not always difficult of attainment, and the general principles underlying the proper hygiene of the mouth and teeth should be laid down.

Errors of vision and the causes of deafness are two very important subjects, and when these have been duly considered the methods of examining for errors of refraction and of testing the auditory power should not only be explained but actually demonstrated to the students by means of cases drawn from the various school clinics where these exist, or otherwise from the special departments of some hospital or medical school. Defective speech, such as stammering and lisping, might form the subject of at least one lecture. This might be followed by a description of the commoner types of mental defectives, such as mongols, cretins, simple primary amentias, hydrocephalic and microcephalic idiots, and so on. The special training of such children should be indicated, and every effort made to instruct the student in the principles on which the education of mentally defective children should be based.

A few lectures on the commoner ailments of school children, their recognition and proper management, might follow. Among these we may specially mention adenoids, enlarged tonsils, nasal catarrh, eczema, any other skin troubles, chorea, habit spasms, hordeolum, bronchial catarrh, headache, enuresis, and so-called "growing pains." The various infectious diseases must also be taken up very carefully, with special reference to the period necessary for the exclusion of infected children from school. The important subject of school closure in relation to infectious diseases must not be overlooked. The mode of disinfecting schools and classrooms would form an appropriate subject for the closing lecture at this section of the course.

As tuberculosis is so prevalent among children of school age, at least a couple of lectures might well be devoted to the teaching of this subject. The symptoms and physical signs specially presented by children should be emphasized, and care taken to indicate the frequency with which the bronchial glands are invaded. The method of detecting such involvement by physical examination should be practically demonstrated. The importance of enlarged cervical glands in relation to tuberculosis of the lungs should be referred to, and the importance of having these attended to early must be impressed upon the student.

A few lectures might be added on such subjects as foods and dietaries, sleep, exercises and games, postures, and moral training. The concluding lectures in the course will deal with choice of school sites, lighting, heating and ventilation, and with sanitary fittings as well as with subjects of a kindred nature which should readily occur to the lecturer who understands and appreciates the importance of the course he is giving. Such is merely an outline of a course of lectures on school hygiene which we consider would better enable the junior practitioner of medicine to fill the post of school medical officer with acceptance. If, after attendance at such a course of lectures a special certificate could be given which would be recognized as a *sine qua non* in applying for such posts, a distinct advance would have been made. In fact, we are strongly in favor of the institution of a special diploma in school hygiene, the following courses of instruction being necessary before the candidate is admitted to examination:

1. Practical instruction in children's diseases (three months).

2. Examination of the eye, ear, nose, and throat (three months).

3. School hygiene, as outlined above (six months), the course to include practical examination of school children under a specially recognized teacher.

The possession of such a diploma would be a guarantee that the candidate is practically qualified to act in the desired capacity. It would mean only a year's special training, and very little additional expense to the student. If such a diploma were instituted, and satisfactory instruction given in school hygiene, the standard of the school doctor would be raised and his money-earning power increased. His status would at the same time be considerably enhanced. At the present time there is no doubt that many school doctors are looked upon as little better than school teachers and paid accordingly. Our suggestions, if acted on, would prevent this, and compel school authorities to set a higher value on the services of the school medical officer.

THE SERUM TREATMENT OF PNEUMONIA IN INFANTS AND YOUNG CHILDREN, WITH GENERAL AND COMPARATIVE MORTALITY STATISTICS OF THIS DISEASE.*

By E. MATHER SILL, M.D.,

NEW YORK,

ATTENDING PHYSICIAN AT THE GOOD SAMARITAN DISPENSARY IN DISEASES OF CHILDREN; LECTURER IN DISEASES OF CHILDREN IN THE NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL.

Pneumonia has been proved to be a bacterial infection of the lungs, and statistics from numerous cities and States have shown that the death rate from this disease has steadily increased during the past forty years, while the mortality of tuberculosis of the lungs has been nearly stationary for the past twenty years and its ratio to population decreased. The United States census of 1900 gives the total number of reported deaths from pneumonia, during the census year, as 105,971, which is a death rate of 106.1 in every 1,000 deaths from all causes, in other words, more than one-tenth of all deaths in the country were due to pneumonia.

The total number of deaths in the United States registration area (51.8 per cent. of total population) from tuberculosis of the lungs for the year 1908 was 67,376, and the corresponding death rate was 149.6 per 100,000 population, while during the same period there were 61,259 deaths from pneumonia, or a death rate of 136 per 100,000 population. This was a falling off of 6,061 from the year 1907, which had a rate of 161.2 per 100,000. During the same

*Read before the City Hospital Alumni Society, December 14, 1910; and before the Section on Pediatrics, Medical Society of the County of Kings, Brooklyn, February 24, 1911.

year (1907) the mortality from tuberculosis of the lungs per 100,000 was 158.9. In other words, nearly as many and possibly more on an average are dying at the present time from pnuemonia as from tuberculosis of the lungs. In certain cities the mortality from pneumonia is much greater, as has been shown, than it is in the registration area of the United States as a whole. In 1908 there were in the registration area 691,574 deaths from all causes, 87 per cent. of which were due to pneumonia; in other words, there were 87 deaths from pneumonia in every 1,000 from all causes.

In 1907 there were in old New York and Brooklyn combined 9 deaths from smallpox, 1,614 from diphtheria and cramps, 718 from measles, 742 from scarlet fever, 355 from whooping cough, making a total of 3,438 deaths from these acute contagious diseases. During the same year there were 11,037 deaths from pneumonia, or more than three times as many deaths from this cause alone; and we who stop to consider know that a large proportion of measles and whooping cough cases really die of secondary bronchopneumonia, but, of course, are not recorded under that heading.

In 1907 there were 8,545 deaths from pulmonary tuberculosis, or 2,492 less than the number of cases dying of pneumonia. Osler declares pneumonia to be the most fatal of all acute diseases. While, according to Wells,[1] the deaths from pneumonia in Philadelphia have steadily risen from 5 per cent. of the total mortality in 1861 to 12.5 per cent. in 1902, and statistics from old New York (Manhattan and Bronx) and Brooklyn combined show pneumonia was 6.3 per cent. of the total mortality in 1868 and 14.9 per cent. in 1907. In 1904-5 more than one-eighth of the deaths in Chicago were due to pneumonia.

The following tables give the decennial death rate from principal causes and from pneumonia, pulmonary tuberculosis, diphtheria, measles, whooping cough, scarlet fever, cerebrospinal meningitis and smallpox in the former City of New York (Manhattan and Bronx) and former City of Brooklyn (Borough of Brooklyn), combined, during the years 1868 to 1907, inclusive:

DECENNIAL RATE PER 1000 POPULATION.

Years.	All Causes.	Pneumonia.	Tuberculosis of Lungs.	Diphtheria Croup.	Measles.
1868–1877	27.17	2.02	3.76	1.54	.28
1878–1887	25.27	2.27	3.58	1.70	.37
1888–1897	23.62	2.84	2.76	1.30	.31
1898–1907	19.12	2.71	2.24	.53	.20

	Whooping Cough.	Scarlet Fever	Cerebro-spinal Meningitis.	Small-pox
1868–1877	.37	.91		.48
1878–1887	.31	.74	.11	.07
1888–1897	.25	.39	.10	.03
1898–1907	.12	.20	.17	.02

This table shows that for the period 1868-1877 for every 10 deaths from pneumonia there were 18 deaths from pulmonary tuberculosis, while during the period 1898-1907 (40 years after) for every 10 deaths from pneumonia there were only 8 deaths from pulmonary tuberculosis and a steady increase in the mortality from pneumonia. The mortality of all the other diseases in the table has decreased with the exception of cerebrospinal meningitis; namely, diphtheria and croup, measles, whooping cough, scarlet fever, and smallpox.

Taking the different census periods of old New York City (Manhattan and Bronx) and the mortality of pneumonia and pulmonary tuberculosis of children under 5 years of age, we obtain the following figures:

TOTAL UNDER 5 YEARS.

Year.	Census.	Pneumonia.		Pulmonary Tuberculosis.	
		No. Cases.	Mortality per 1,000.	No. Cases.	Mortality per 1,000
1870	942,292	939	1.00	152	.16
1880	1,206,299	1311	1.09	171	.14
1890	1,573,501	2038	1.35	151	.10
1900	2,050,600	3327	1.60	116	.05
1905	2,384,326	2899	1.21	138	.06

This table of children under 5 years of age also shows an increase in the mortality from pneumonia for the past 35 years and a decrease in the mortality from pulmonary tuberculosis per 1,000 population, but the difference is not as marked as in the previous table, which includes all ages.

Any remedy which theoretically gives promise of an advance in therapeutics in this particular direction, even though it may be in the experimental stage, has arrested our attention. I, therefore, about a year ago, became interested in the polyvalent serum for use in pneumonia. The serum which was used is a polyvalent composite serum, that is to say, obtained from diphtheria-immune horses that have been subjected to a prolonged and progressive immunization with a mixed culture of the pneumococcus taken from several strains of pneumococci from a number of cases of pneumonia in different stages and of different degrees of severity. The reason the serum is obtained from diphtheria-immune horses is that it has been shown that the presence of diphtheria antitoxin in antibacterial serums adds very much to their efficacy; this is probably due to the fact that the antitoxin favors leucocytosis and thus increases phagocytosis, which is a condition to be desired in pneumonia, since it favors the destruction of pneumococci in the blood current and tissues, as it has been shown by Rosenau[2] that in pneumonia there is always a pneumococcemia. Rosenau examined the blood of 175 cases of pneumonia and isolated the pneumococcus in 160, or over 91 per cent. It is well known that a high leucocytosis is a favorable sign in pneumonia and it has been shown that the higher the leucocytosis the fewer the pneumococci found in the blood.

The serum was injected subcutaneously in doses of 10 c.c., at varying intervals, depending upon the symptoms and the effect it had on the patient. In some cases one injection seemed to be sufficient to relieve the symptoms and check the disease, while in others repeated injections of 10 c.c. were given every day or at longer intervals, although not always with favorable results. I think, perhaps, in these latter cases if larger doses had been given or the serum had been injected at more frequent intervals it might have made a difference and given a more im-

[2] *Journal of the American Medical Association*, March 18, 1905, page 87.

mediately favorable result. In all, 12 cases were treated by means of the serum—8 males and 4 females. Their ages ranged from 5 months to 3 years; all but two were under two years, and 3 of these were under 1 year. There were 3 cases of lobar pneumonia and 9 cases of bronchopneumonia. Two cases died, 1 of complicating empyema and 1 of extensive double pneumonia, marasmus, and cardiac failure. (Mortality 16.6 per cent.) Two other cases besides those that died were not helped by the serum, but the other eight cases were all more or less improved, and in some of the cases the effect of the serum seemed marked.

In glancing over the temperature charts it will be seen that there was not infrequently a negative phase, as shown by a rise of temperature following the injection, this being followed by a fall in temperature and improvement of symptoms. Those cases in which the serum was given early in the disease seemed to be most benefited by its use.

Dr. L. Emmet Holt has shown recently, by means of a great number of cultures taken from the bronchial secretion of babies having pneumonia, and also from the lungs of babies that died of pneumonia, that a large majority of cases are mixed infections. He has also shown that the same bacteria are found in the bronchial secretion in bronchitis as in pneumonia, which fact has hitherto not been appreciated, and this sounds a note of warning that pneumonia is only a step further on in the extension of inflammation and solves the reason why simple cases of neglected bronchitis in infants frequently terminated in pneumonia.

The post-mortem findings under the supervision of Dr. Holt corresponded with the clinical findings by sputum cultures. Thus the growth from the lungs of 76 pneumonia cases showed *B. influenzæ* alone, 2; pneumococcus alone, 4; streptococcus alone, 1; *Staphylococcus aureus* alone, 8; *B. influenzæ* and pneumococcus, 5; *B. influenzæ* and streptococcus, 5; *B. influenzæ* and staphylococcus, 7; pneumococcus and streptococcus, 1; pneumococcus and staphylococcus, 11; pneumococcus and catarrhalis, 5; staphylococcus and streptococcus, 10. The remaining autopsies showed various other combinations of the above organisms, or of them with *pyocyaneus, B. diphtheriæ, or B. coli communis*, but not more than two cases of any one variety.

Cultures showed that the *B. influenzæ* played an important part in diseases of the respiratory tract during the winter and spring months, being next in frequency to the pneumococcus. With all the above information so thoroughly worked out by such a careful observer as Dr. Holt it is evident that in the majority of cases of pneumonia in infants we are dealing with an inflammation caused by several varieties of bacteria, consequently, in order to combat this disease by means of a serum or vaccine effectively we should use theoretically a polyvalent serum or vaccine made by means of the varieties of bacteria above mentioned in Dr. Holt's table, according to the combinations that are found in the cultures grown from the bronchial secretion from each individual case. This, however, is not always possible; therefore, the next best serum to use would be one made by means of the bacteria that are most commonly found in the majority of cases, and these we find to be pneumococci, since, in Dr. Holt's table, out of 59 cases where cultures were taken from the lungs, in 26 the pneumococcus, either alone or more frequently together with other varieties of bacteria, was found. In another table of life cultures (bronchial) Holt gives the following figures:

Pneumonia—124 patients, 333 cultures. *B. influenzæ,* patients, 47; cultures, 93; pneumococcus, patients, 94; cultures, 200; streptococcus, patients, 63; cultures, 120; *Staphylococcus aureus,* patients, 116; cultures, 257. Thus it will be seen that the pneumococcus and *Staphylococcus aureus* predominate. Most of the cases examined were primary pneumonias of the broncho type.

Conclusions.—1. It would seem that in finding a specific or cure for pneumonia the path is more or less definitely mapped out; that is, by the use of a polyvalent serum (or vaccine).

2. This serum should be made in a concentrated form to prevent serum sickness, which has previously been the drawback to the animal serums.

3. Extensive culture examinations from the bronchial secretions of pneumonia cases during life and from the lungs of pneumonia cases after death have shown that pneumonia is generally a mixed infection, but in the majority of cases the pneumococcus is present and the prevailing organism.

4. The polyvalent composite serum, while it has not given brilliant results in all cases, is at least an advance in therapeutics in the right direction, and apparently in a number of cases limited the disease.

5. To obtain the best results from the serum treatment of pneumonias of mixed infection the serum should be obtained from horses, not only immunized to the pneumococcus, but also to the other germs which are commonly found to be present in these cases.

6. It is important that in pneumonia the child be injected early in the disease with good sized doses of a concentrated serum.

7. In comparing the bacteriology of lobar and bronchopneumonia we find that the lobar type of the disease is more apt to be due to the pneumococcus alone than in the broncho type; this explains why such good results have followed the use of serum obtained from horses that have been immunized with the pneumococcus in lobar pneumonias.

8. Why is it not just as plausible to use a serum for the treatment of pneumonia as for diphtheria and meningitis?

9. We have heard a great deal of late of the destruction of humanity by the "Great White Plague." It is time for us to awaken to the fact that pneumonia is just about as bad a scourge, and that the death rate from this disease is not decreasing as is that of other diseases, but, on the contrary, has markedly increased in the past 40 years.

Case I.—Jennie S., 9 months. First seen January 5. Acute general bronchitis; child sick 3 days. Temperature 103°, respiration 50. January 8—Bronchopneumonia left lobe. Temperature 102.8°; respiration 54. Received 10 c.c. pneumolytic serum. January 10—Temperature 104.4°; respiration 60, pulse 150. Both bases consolidated; fine, crackling, crepitant râles. Received 10 c.c. pneumolytic serum. January 11—Temperature 100.6°; respiration 70, pulse 120. Physical signs same as yesterday. Child looks bright. Pneumolytic serum, 10 c.c. given. January 12—Temperature 100.5°; respiration 40, pulse 120. Child seems bright. Signs at left base disappearing rapidly. Small area at right base. Bronchial breathing, fine subcrepitant râles. January 13—Temperature 99.4°; respiration 44, pulse 120. Still fine râles on left and right lung and coarse râles over entire chest. Child seems bright. Coughs a great deal; somewhat cyanosed. January 15—Temperature 100°; respiration 36; both lungs practically clear. Child seems well. Slightly diminished breath sounds and voice sounds at right base. January 18—Lungs cleared up. Temperature 99.4°.

Case II.—Hyman L., 1 year 11 months. First seen March 2. Lobar pneumonia. March 3—Fine crackling râles, bronchial breathing at left base posteriorly, large area of urticaria over liver resembling erysipelas, also over face and back. Tongue heavily coated. Ten c.c. pneumococcus vaccine (40,000,000 bacteria) given. March 4—Urticaria has disappeared. Diminished voice sounds over base. Bronchophony and bronchial breathing about middle of left lung. One c.c. pneumococcus vaccine (40,000,000 bacteria) given. March 5—Temperature 99.4°; respiration 24; bronchial breathing heard over middle of left lung. Pneumococcus vaccine, 2 c.c. (80,000,000 bacteria), given. March 8—Temperature normal, left lung rapidly resolving, bronchial breathing. Bronchophony of left apex still. March 9—Temperature 101°, respiration 28, physical signs marked over right lung. Pneumolytic serum, 10 c.c. given. March 10—Temperature 100.6°. Child feels better. March 11—Temperature normal.

Case III.—Jennie K., 1 year 6 months. First seen August 25. Bronchopneumonia upper left lobe. Temperature 101.5°; respiration 40. Bronchophony, bronchial breathing, and bronchial voice. Ten c.c. pneumolytic serum given. August 29—Temperature 102.2°; 10 c.c. pneumolytic serum given. September 3—Temperature 102.6°, respiration 46. Physical signs same. September 6—Child improved in every respect, lungs clearing. Temperature 100.6°. September 7—Temperature 101°; child improved. September 8—Temperature 102.2°. Lungs clearing rapidly and child is gaining. Ten c.c. pneumolytic serum given. September 13—Physical signs of pneumonia almost disappeared. Child still has a general bronchitis. Temperature 100.2°. September 15—Child is improving, appetite is good. Temperature 99°. Lungs all cleared, with exception of bronchitis.

Case IV.—Louis B., 1 year 4 months. First seen August 30. Bronchopneumonia principally on left side; had whooping cough two weeks, fever ten days. Temperature 103°, respiration 60. Received 10 c.c. pneumolytic serum. August 31—Temperature 103°, respiration 60. Bronchial breathing over both lungs, fine crackling râles heard. September 2—For one day after injection was unable to see patient. Mother reports child felt better, temperature lower, 102°. September 3—Temperature 102.2°, respiration 50, lungs much clearer and in better condition. Received 10 c.c. pneumolytic serum. September 6—Temperature 99.6, respiration 54. Lungs clearer, child looks brighter, coughs less. September 15—Temperature 99.8°, respiration 40. All sign of pneumonia has disappeared. Child has a general bronchitis. Whooping cough is better. September 17—Temperature is normal, 98.4°; still has bronchitis, lungs are clear and child is very much better in every respect.

Case V.—David D., 1 year 1 month. First seen January 7 with bronchopneumonia. Fine and coarse râles heard in both lungs. Respiration 40, temperature 104.4°, pulse 150. Fine crackling râles and bronchophony about center of right lung posteriorly. Increased voice sound on left side and prostration. Received 10 c.c. pneumolytic serum. Respiration labored. January 18—Temperature 101.2°, respiration 36; child seems very much brighter, coughs less. Lungs are clearer, full of coarse râles; pneumonic signs practically disappeared. No serum given. January 19—Temperature 99°; child much better. Large moist râles all over chest.

Case VI.—Willie G., 2 years old. First seen September 19. Bronchopneumonia right base. Temperature 104°, respiration 50. Ten cubic centimeters pneumolytic serum given. September 20—Temperature 102°, respiration 40. Child has general bronchitis. Consolidation of right base apparently resolving. September 21—Temperature 99°. Lungs clear with exception of slight bronchitis. September 22—Temperature 98.4°. Child much better. Lungs practically clear.

Case VII.—Nathan K., 1 year 5 months. First seen February 5. Bronchopneumonia. Temperature 102.2°, respiration 48, prostration; exaggerated breathing on right side, diminished on left side, almost absent on lower left side. Heart's apex beat displaced to right of sternum one inch. Dry râles on left side. February 8—Temperature 102.8°. Amount of fluid just about the same. February 9—Temperature 102.4°, respiration 48. Physical signs same. Bronchopneumonia at right base. Ten cubic centimeters pneumolytic serum injected. February 10—Temperature 101°. Child seems better. Physical signs on right side disappearing rapidly. February 11—Temperature 103.4°, respiration 48. Fluid taken from chest: 400,000,000 staphylococcus mixed given. *Staphylococcus albus* found in culture growth. February 20—Sent to hospital to be

operated upon for empyema. Child was operated upon three times. Seven weeks after last operation child died.

Case VIII.—David K., 1 year 5 months old. First seen September 9. Lobar pneumonia and whooping cough. Temperature 101.8°, respiration 54, exaggerated voice sounds and breath sounds at both apices. Diminished voice sounds and breath sounds over both bases, especially left base, with flatness over left area. Ten cubic centimeters pneumolytic serum given. Child has fever and is continually moaning and crying. September 10—Temperature 102°, respiration 60. Diminished voice sounds and breath sounds left base, exaggerated voice and breath sounds right apex posteriorly. Received 10 c.c. pneumolytic serum. September 12—Bronchial breathing and bronchophony right apex. Temperature 103.4°, respiration 60. Consolidation right apex. Ten c.c. pneumolytic serum given. Child did not return for treatment and was lost sight of for the time but afterward recovered.

Case IX.—Louis F., 11 months. First seen March 15. Bronchopneumonia. Temperature 103°, respiration 46. Pneumonia left base; bronchophony. Received 10 c.c. pneumolytic serum. Also right apex involved. April 9—Temperature 101.6°. Received 10 c.c. pneumolytic serum. April 11—Temperature 101.6°. Lung somewhat improved; 40,000,000 pneumococci given (1 c.c.). April 12—Physical signs same. Temperature 100.4°; 40,000,000 pneumococci given (1 c.c.). April 13—Temperature 102°. April 14—Temperature 101.6°. April 18—Temperature 100.2°, respiration 60. Physical signs same, also small patch at right apex. Grunting and sighing. Ten c.c. pneumolytic serum given. April 19—Child slept four hours and feels much brighter to-day. Mother says child has no fever. April 20—Temperature 99½°, respiration 50. Lungs clearing. April 21—Temperature 100.8°, respiration 50. Cyanosis; 1/200 gr. strychnine q. 3 h. Pulse 150. April 22—Temperature 101°, respiration 50, lungs better. April 23—Temperature 100.2°, respiration 52. Lungs clearing. Child has good appetite. April 25—Temperature 99.6°; lungs better. April 26—Temperature 100.2°; physical signs same. April 27—Temperature 100°, respiration 56. Physical signs same. Great difficulty in breathing. Cyanosis 10 c.c. pneumolytic serum. Was not seen April 28 and 29. April 29—Child died.

Case X.—Rose B., 1 year. First seen August 26. Bronchopneumonia. Child sick with fever and cough. Temperature 103°, respiration 72. Marked prostration. Ten c.c. pneumolytic serum given. Left base principally affected. September 2—Mother says child felt worse immediately after injection, but felt better afterward. Left lung consolidated, right lung slightly affected. Temperature 103.2°, respiration 70. September 17—Child better. Temperature 99.5°, respiration 54, child restless. Nearly whole of the left lung is involved. Bronchial breathing. Bronchophony and dullness over left lung. Ten c.c. pneumolytic serum given. Lung is resolving. Child has general bronchitis. September 19—Temperature 101°, respiration 46. Whole left base consolidated. Bronchial breathing, bronchophony, large area of swelling and inflammation about the point where the pneumolytic serum was injected. Needle infection with cellulitis and abscess formation. September 21—Temperature 99.6°, respiration 60. Ten cubic centimeters pneumolytic serum given. Physical signs practically same. Small area about the size of a twenty-five-cent piece of consolidation on right side, lower half of left lung consolidated. September 22—Temperature 101.6°, respiration 50. Child restless, physical signs same, chest râles are larger. September 23—Temperature 100.8°, respiration 50. Physical signs about the same. Still considerable congestion and swelling at the point where injection was given. September 24. Temperature 101.6°. Physical signs same. Considerable swelling over abdomen where injection was given. Respiration 60. Combined vaccine (1 c.c.) given. September 26—Temperature 99°, respiration 46. Left lung resolving. Coarse râles heard over both chests. Child acts brighter and better. Bronchophony, bronchial breathing still present. Considerable edema present at the point where serum was injected. One c.c. combined vaccine given. September 27—Temperature 99.2°, respiration 40. Left lung resolving. Child has general bronchitis and feels brighter and has good appetite. September 28—Temperature 99°, respiration about 60. Lungs clearing rapidly. Still bronchophony. Child looks well. Still considerable edema at the point of injection. One c.c. combined vaccine given. September 29—Lungs clearing rapidly. Still bronchophony. Child feels better. Temperature normal. Edema of the abdomen disappearing. October 1—Temperature 102.6°, respiration 60. Left lung resolving. Still has bronchial voice. One c.c. combined vaccine given. October 4—Temperature 99.6°. Child has general bronchitis. Left lung is practically resolved. Still slight bronchophony. Child feels much better. Appetite good. Edema of abdomen disappearing. Combined vaccine given (1 c.c.). October 5—Temperature 99½°. Child looks brighter and feels better. Bronchophony over left side. Lungs clearing rapidly. Respiration 40. Abscess on the left side in the abdominal muscles—result of needle infection. Abscess opened and small amount of dark jelly-like fluid removed. October 6—Temperature 99½°, respiration 36. Lungs practically clear. Child has slight bronchitis.

Case XI.—Rose S., 3 years old. First seen February 23. Lobar pneumonia (relapse or reinfection). Temperature 102.6°. Few râles and slightly diminished voice sounds on left side, posteriorly, some thickening of the pleura. Had pneumonia three weeks ago on the left side, not entirely resolved. Fine crackling râles on left side posteriorly. Dullness, exaggerated voice sounds over all left lung. Respiration 40. Ten c.c. pneumolytic serum given. February 28—Temperature 101.8°. Needle inserted into left side. Small amount of pus withdrawn. Culture and smear taken. March 1—Temperature 100.2°; 40,000,000 pneumococci given. March 2—Given 400,000,000 staphylococcus mixed. Culture growth shows *Staphylococcus albus*. March 3—Temperature 104.3°, respiration 40. Ten c.c. pneumolytic serum given. Fine râles, bronchial breathing at upper border of lower left lobe near spine. March 4—Physical signs same, extremely restless. Cries a great deal. Temperature 104.5°, respiration 72. Ten c.c. pneumolytic serum given. March 5—Temperature 105°, respiration 70. Physical signs same. Ten c.c. pneumolytic serum given. March 7—Temperature 105.2°, respiration 48. March 8—Temperature 99.6°, respiration 36. March 9—Bronchophony over area of left side. Child feels much better. March 10—Physical signs same. Temperature 100°. Ten c.c. pneumolytic serum

given. Fine râles. Bronchial breathing. March 12—Temperature 101.4°. March 14—Temperature 100°. Bronchial breathing. Ten c.c. pneumolytic serum given. Bronchophony over left lung. March 15—Temperature 104°. March 17—Temperature 101.2°. Bronchophony over left lung. Ten c.c. pneumolytic serum given. Von Pirquet test made and was negative. March 19—Temperature 102°. Bronchophony over left lung. March 22—Temperature 101.4°. Bronchophony over left lung. March 25—Temperature 104.2°. Dullness and bronchophony over left apex. Ten c.c. pneumolytic serum given. March 28—Temperature 102.8°. Ten c.c. pneumolytic serum given. March 30—Temperature 101.5°, respiration 40. Physical signs same. March 31—Temperature 101.2°. Pneumococcus vaccine given, 1 c.c. or 40,000,000 bacteria. April 23. Temperature 101.3°. Fine crackling râles. Bronchial breathing. Dullness at apex of right lung posteriorly. September 13—Lungs clear with the exception of a slight bronchitis over the large tubes. Mother says that the child got much better after the last injection of pneumococcus vaccine and fever stopped.

Case XII.—Izzy B., 5 months. First seen January 23, 1910. Bronchopneumonia. Temperature 101.8°, respiration 40. Two weeks sick. Consolidation of right base. Bronchophony, dullness, fine crackling râles over same area. Persistent hacking cough. Slight stiffness of neck. January 24—Temperature 99.2°, respiration 36. Van Pirquet test negative. Ten c.c. pneumolytic serum given. January 26. Temperature 99°. Physical signs practically the same. January 27—Temperature 102.2°. Physical signs same, dry hacking cough. January 29—Temperature 100.5°. February 1—Temperature 98.4°. Physical signs same. February 3—Temperature 99.4°. February 10—Child is all well. Baby weighs fourteen pounds.

NOTE ON TREATMENT OF DIABETES MELLITUS, WITH TABLE OF CARBOHYDRATE EQUIVALENTS.

By HERBERT SWIFT CARTER, M.D.,

NEW YORK,

ASSOCIATE IN MEDICINE, COLUMBIA UNIVERSITY; ATTENDING PHYSICIAN TO THE LINCOLN HOSPITAL; CHIEF OF MEDICAL CLINIC PRESBYTERIAN HOSPITAL DISPENSARY.

Whatever the opinion may be as to the value of various drugs in the treatment of diabetes mellitus, and their legitimate field is small and almost entirely symptomatic, it is generally conceded that the only real success comes through a proper dietary regulation, and as the chief symptom, glycosuria, is dependent on the incomplete metabolism of carbohydrates, any plan for efficient treatment must center about the proper training of the organism to reacquire, to some extent, the lost power of properly burning the carbohydrates. In other words, it is the partial reeducation of the individual to the proper digestion of starch and the sugars, power which has been lost through some defect in the physical economy of the secretions, notably the pancreatic internal secretion.

In all but the most severe cases, where glucose is manufactured out of protein, and fat, (?) some degree of tolerance can almost always be reacquired, provided only proper attention is given to details. The greatest stumbling block is not, as a rule, the lack of ability to bring the organism into condition to do this, but the fact that it means the entire readjustment of a person's dietetic habits of a lifetime, something which it seems too difficult for many patients to accomplish, and unfortunately one meets many victims of this disease, particularly in its milder grades, who, because they do not feel ill, find it difficult to grasp the *absolute necessity* of getting rid of the sugar output. They also fail to realize, and this is often the medical man's fault, that the disease is most apt to progress unless properly treated, besides exposing the patient to all sorts of intercurrent infections, since hyperglycemia furnishes the most excellent conditions for the development of numerous microorganisms, notably the tubercle bacillus, which gains rapid headway in glucose saturated tissues, to say nothing of the gangrene, dental caries, neuralgia, etc., that are such frequent concomitants of diabetes. All of this can often be entirely avoided and the patient live out his or her days in good health, always with the probability that as time goes on their tolerance for carbohydrate food can be considerably increased, so that the rigid dietary necessary during the earlier months of treatment no longer maintains, and one is enabled thereby to return more nearly to a normal dietary, although probably never being able to return to an unstinted use of this class of foodstuffs.

There is no intention in this communication to go into all the details of the proper management of a case of diabetes, and one is referred especially to von Noorden's writings for this, but the main object here is to show the use of the accompanying table of carbohydrate equivalents and the method of using it.

Given a mild or moderately severe type of the disease, the first object to be gained is the establishment of the degree of the individual carbohydrate tolerance, which is best done by putting the patient on von Noorden's standard diet or at least restricting absolutely the intake of carbohydrate food to 100 gms. per day in the form of white bread.

If, after two days of this diet, sugar is still being excreted, the amount of bread is reduced to 50 gms. and in every instance the day's supply is divided equally between the three meals. If sugar still appears after two days of this (a twenty-four hour specimen is always necessary for all these analyses), the daily quantity is reduced one-half again, *i.e.*, to 25 gms., and so on down or up to the point at which sugar just appears in the urine, the last changes being made with small amounts, *e.g.* 5 gms., increased or decreased until this point is reached. The amount of white bread just below this point, *i.e.* the largest amount which can be taken without sugar appearing, is taken as that particular patient's point of carbohydrate tolerance. Take for example a case in which 60 gms. of white bread represents the tolerance, the plan then should be to put this patient on a diet with full protein ration, but not excessive on account of the disadvantage of this to the kidney functions, the fats being given in large amounts to supply the necessary calories, after taking into consideration the value of the carbohydrate to be given. This should not be over one-half the tolerance, viz., 30 gms. in this particular case. The carbohydrates are kept at this low level for from two to three months, at the end of which time it is usually possible to raise the limit considerably and if the point of tolerance should be again determined, as in the first in-

stance, it would be found that the amount of carbohydrate the individual was capable of metabolizing would be considerably higher. However, it is best not to go to the point of again producing glycosuria to determine this new point of tolerance, but a moderate increase may be made in the carbohydrates for another couple of months, when it may again be increased, watching the urine to be sure it remains sugar-free.

The chief reason for reducing the original intake of carbohydrate to one-half the tolerance is because, although the urine may become sugar-free rather promptly on the full amount, it does not mean that the hyperglycemia has also disappeared—as a matter of fact, it is usually not so, as this disappears much more slowly than the sugar leaves the urine, as proved by estimation of the percentage of glucose in the blood, a process too complicated for the routine care of these cases. The hyperglycemia does, however, diminish on the half ration of carbohydrate, after which it is safe to go ahead a bit further with the increase of this form of foodstuffs.

Of course these 30 gms. of carbohydrate in this particular hypothetical case we are considering represents a pitiful allowance of carbohydrate food and one upon which practically no patient can remain contented, hence it is necessary to increase the bulk of the food without actually increasing the amount of carbohydrate. It is here that the value of the accompanying table of carbohydrate equivalents becomes evident.

The idea of this table is frankly borrowed from von Noorden's work, although its detail is worked out rather differently here and adapted to an American dietary.

The articles in the list are taken for the most part from the table of food analyses of the Department of Agriculture Bulletin 28 (revised), and from analyses of so called "Diabetic Foods," by A. L. Winton.

The estimations are substantially accurate, although fractions are mostly omitted and the tables err if anything on the safe side, in underestimating rather than overestimating the percentage of carbohydrate.

White bread, with an average starch content of 60 per cent., is taken as the standard, as it is with this article that the point of carbohydrate tolerance is determined, and the other carbohydrate foods are tabulated in columns on the basis of white bread in amounts of ¼ oz. or 7.5 gms., ½ oz. or 15 gms., 1 oz. or 30 gms., 2 oz. or 60 gms., 2½ oz. or 75 gms., etc. By simple multiplication the quantities can be indefinitely extended. The metric table is used by preference as being much easier. A change can be made to the English table by dividing the number of gms. by 30, which will give ounces with fractions of an ounce.

The practical application in the use of this table in the case taken as an example, with 30 gms. (1 oz.) as the amount of carbohydrates to be given, is as follows:

EXAMPLE NO. 1.

Say we take:						
Proto puff No. 1	45.0 gms.	equals	7.5 gms.	white	bread	
Potato	22.0 "	"	7.5 "	"	"	
Oatmeal	40.0 "	"	7.5 "	"	"	
Beets	33.0 "	"	3.75 "	"	"	
Peaches	25.0 "	"	3.75 "	"	"	
	145.0 "	"	30.0 "			

EXAMPLE NO. 2.

(If allowance is 45 gms. white bread.)

Potato	22.0 gms.,	equals	7.5 gms.	white	bread	
Oatmeal	40.0 "	"	7.5 "	"	"	
Corn bread	20.0 "	"	15.0 "	"	"	
Carrots	65.0 "	"	7.5 "	"	"	
Orange	40.0 "	"	7.5 "	"	"	
	187.0 "	"	45.0 "	"	"	

that is, we can give a varied carbohydrate diet with a bulk of 145 gms. of food worth just 30 gms. of white bread, which is our allowance, or in the second example, 187 gms. mixed carbohydrates equals 45 gms. white bread.

This is sufficient for an example, as the practical application to each case is simple and only a matter of detail and a little practice.

White bread	¼ oz. or 7.5 gms.	½ oz. or 15 gms.	1 oz. or 30 gms.	1½ oz. or 45 gms.	2 oz. or 60 gms.	2½ oz. or 75 gms.
Potato	22	44	88	132	176	220
Hominy (cooked)	25	50	100	150	200	250

Of course, the patient must weigh the food, there is absolutely no other satisfactory way. Sometimes after long practice one can become so familiar with the value of the equivalents that the eye is practically sufficient for measuring the amount, but it is never accurate and is never to be recom-

mended. In other words the patient must live by the scales, and when this principle is finally grasped and insisted upon the dietary treatment of this disease resolves itself into a routine easily accomplished. It is naturally advisable to weigh the protein and fat foods, but in busy America it is usually not possible to get the patients to do this for long periods nor is it quite so imperatively demanded as in the case of the carbohydrates, although it is well for them to train their eye for amounts and attempt to harmonize the portions, so sparing the kidney excess of work in the elimination of too large amounts of nitrogen.

REMARKS ON THE SPONTANEOUS DISAPPEARANCE OF MALIGNANT GROWTHS.*

By J. W. GLEITSMANN, M.D.,

NEW YORK.

My attention has been drawn to this important subject by a publication of Dr. Jonathan Wright, who also had the kindness to give me additional literary data. Dr. Wright,[1] whose article deals with the microscopic diagnosis of endolaryngeal tumors, says in his introductory remarks that there was no doubt that cases of carcinoma existed which, up to a certain period of their growth, not only showed the typical clinical picture, but which also were diagnosed as such by expert microscopists. Nevertheless the growth disappeared either without any or without a radical operation, and the patient remained permanently in perfect health. In such cases the clinician or surgeon may possibly doubt his own diagnosis, but is rather more inclined to believe in an error made by the microscopist.

Before I relate to you cases reported by different authors, I wish to refer briefly to the interesting experiments made recently in the Rockefeller Institute for Medical Research by Carrell and Burrows,[2] who made important biological observations bearing on the growth and the shrinkage of malignant tumors. The investigators found that cultures of different tissue of grown animals can be made to grow *in vitro* by inoculating a small fragment aseptically into a plastic medium taken from the same animal and placing it in an incubator. Glandular organs show growth already after two days; thyroid and kidney after four to five days. They also observed growth of sarcomatous tissue under similar conditions. They finally extended their researches to growth of sarcoma in different media and found that sarcoma grows rapidly in the plasma of the same animal, but that the plasma of a sarcomatous animal inhibits the growth of sarcoma taken from another animal.

This last observation bears some relation to the communication of the late Dr. Hodenpyl,[3] who treated a woman with carcinoma of the mamma, neck, and liver for four years, whose tumors finally disappeared spontaneously. The ascites existing at the time was frequently withdrawn and the fluid first injected into mouse and rat cancer, and after its succeeding necrosis and disappearance was also used in patients with cancer. In no case ill sequelæ resulted; in all cases the tumors decreased in size, and in several of them they had completely disappeared at the time of publication.

When quoting now a number of authors and their cases, it is by no means my intention to give a complete bibliography, as my sole aim was to call your attention to this important subject.

To my knowledge the first article appeared in the *Lancet*, 1899, by Powers,[4] under the significant title, "Vanishing Tumors," as not all his cases were of a malignant type. I shall relate only a few of them.

He describes the case of a boy, eight years of age, with cystic lymphangioma of the left side of the neck, often tapped; later excision of a part of it at the posterior angle of the neck. Two months later the lower part of the growth was very large, but five months later the boy had several attacks of lymphangitis, after each of which the tumor decreased and finally disappeared. After a trauma six to eight different tumors developed on the scalp of a man, the last one being examined under the microscope and pronounced as fibrosarcoma. In the discussion their appearance was called by Baker "withering sarcoma," and Guthrie said that there were authenticated instances of spontaneous disappearance of benign and malignant growths. He believes the cause to be the cutting off of the blood supply.

Dr. Greene of Alabama[5] reported, 1909, the case of a physician, 50 years old, who had a small, red growth of the size of a grain of wheat at the center of the left vocal cord, which increased in size within two weeks. Greene, as well as Dr. Ingals, made the clinical diagnosis of carcinoma, but excision of a specimen for microscopic examination was refused. When the doctor saw the patient, four months later, the tumor had disappeared without any treatment. It must be conceded that, from a strictly scientific point of view, the case does not furnish a positive proof.

Koschier[6] ventilates the question of certain benign features of some sarcomata and carcinomata and relates eight histories of patients of his own. He says that the growth of malignant neoplasms depends (1) upon the greater or lesser resistance of the tissues; (2) upon the locality and functions of the organ (greater frequency in woman on account of the disposition of the genital organs to the disease); (3) upon the quantity of fibrous tissue; and (4) upon the scarcity of lymphatic vessels (slow growth of cancer of the vocal cords). There is a difference in the virulence of some carcinomata; lymphorsarcoma disappears sometimes completely after a minor, certainly an incomplete, operation. Six of his cases of laryngeal and tracheal tumors had no recurrence for years after a non-radical proceeding; one of his two cases of carcinoma of the rhinopharynx, whom he had under treatment for nine years, showed still no cachexia.

Gould[7] speaks of the cancer problem in the Bradshaw lecture, 1910, in a concise, clear manner. Cancer is a disease that occurs in all vertebrate animals. Thousands of successful experiments have proven that cancer can be transferred from host to host; *e. g.* upon mice, rats, dogs. As to the etiology, he says: "Considering the fundamental law of multiplication and division of the fertilized human ovum, we find that cancer is the result of a breach or failure of the fundamental cell-law; that it is not a disease attacking the body from without. Immunity against cancer is based upon (1) the power of the living cell to conform to the law of normal development and to avoid that increased multiplication, defective differentiation, connoting cancer; (2) the opposition to the intrusion of cancer cells

*Read at a meeting of the German Medical Society of New York, March 6, 1911.

into and their development in heterogenous tissue; (3) inhibition of the growth of cancer, or destruction of living cancer cells."

In conclusion Gould gives histories of seven patients with undoubted cancer who were either entirely cured or practically well but in whom different therapeutic measures had been adopted. Of six women in three cophorectomy was performed; in three Röntgen rays were applied, the latter also in a man, who seven years later was still working as postman.

Although these brief remarks are only fragments of this great problem, they will have shown you the possibility and the occurrence of a spontaneous disappearance of malignant growths, and it is desirable that greater attention should be bestowed on this subject, also in the field of the other special branches of medical science.

A CONTRIBUTION TO THE DIAGNOSIS OF DUODENAL ULCER.

By M. GROSS, M.D.,

NEW YORK,

ATTENDING GASTROENTEROLOGIST TO THE HAR MORIAH HOSPITAL.

To attempt, even in the smallest degree, to add any further material to that already available as the result of the fundamental investigations of men like Moynihan, Mayo, John Munro, and E. A. Codman of Boston would mean carrying coal to Newcastle. To these men we owe a thorough insight into the origin, course, and termination of duodenal ulcer; to them we are indebted for the close observations of the pathological process in man; and, finally, the merit of harmonizing the well-described pathological changes with the clinical manifestations is theirs. In Europe, too, the classical examinations of these investigators are gradually being recognized by Chvostek, Kraus, and others. Codman, backed by a wealth of experience, is responsible for the following statement: "Duodenal ulcer is a common disease; it is at least twice as common as gastric ulcer, and nearly as common as acute appendicitis."

There are many transitions from cases in which post-mortem, and then mostly in microscopic cuts, traces of a healed ulcer can scarcely be detected to those cases in which at the time of operation "the uninflamed, quiescent, tiny, chronic, duodenal ulcers" are encountered, and to the distinct and extensive acute or subacute inflammatory conditions of the parts surrounding the ulcer in the stages of exacerbation. "This inflammatory and edematous exudate about an ulcer is absorbable, and varies from time to time in extent," and corresponds to the acute attack of a chronic ulcer which otherwise presents but slight manifestations. No doubt ulcers of the duodenum can in exceptional cases run a course without displaying symptoms, until hemorrhage or perforation discloses the nature of the affection. In the great majority of cases, however, the symptoms are of such a prominent nature that, in conjunction with a conscientiously established anamnesis, they can be relied upon for making an almost positive diagnosis.

Following a more or less characteristic alternating picture of well-being and ill-being, a "painful dyspepsia," the presence of which with short or long intermissions may sometimes be elicited from the history, the acute stage, the attack, may break out more or less suddenly, marked by violent characteristic paroxysms of pain: Moynihan's "hunger-pain," so named from its usual occurrence with an empty stomach 2½ to 3 hours after partaking of a meal. Ingestion of food, alkalies, even a little wine (Chvostek) will remove it (occlusion of the pylorus). Rigidity of the muscle in the duodenal region to the right of the parasternal line is likewise met with, as in appendicitis. A painful area can also be distinctly demarcated by hammer percussion. The acute attack is frequently accompanied by vomiting of yellowish-green mucous matter. Temporary and excessive dilatations (pylorospasms) are frequently found, and belong to the later stages of duodenal ulcer. Extensive hemorrhages and perforations are relatively rare, and should be regarded only as "accidental manifestations" of ulcer. The quantity of hydrochloric acid present in the gastric contents varies. It may also be below normal or entirely absent. Icterus as a sign of inflammation spreading by contiguity downwards is not of rare occurrence, but as a rule the jaundice of duodenal ulcer runs a much milder course than that occasioned by gallstones.

Occult hemorrhages in the stools were regarded as proving almost conclusively the diagnosis, provided they occurred repeatedly and other sources of hemorrhage could be excluded. No meat is allowed for several days before the examination for occult hemorrhages, and it is equally imperative to exclude hemorrhages from the nose, gums, esophagus, stomach, and other parts of the intestine; likewise inflammations, ulcers, zooparasites, hemorrhoids, etc. "Generally speaking, the absence of blood in the stools is not an exception, but rather the rule" (Codman). Examination for blood would furnish a more positive proof if it were possible to effect a *direct* demonstration of hemorrhage of a duodenal ulcer if such existed. Einhorn lets patients swallow a small bucket attached to a silk thread. Upon withdrawal of the thread, after ten or twelve hours, that part of it which lay contiguous to the ulcer is expected to have turned red. According to Einhorn, it is possible to determine not only the presence, but also the seat of an ulcer by the distance of the discolored part of the thread from the teeth. Aside from the fact that the desired passage of the small bucket through the pyloric ring may not always succeed, Einhorn presupposes that the thread will actually run across the ulcer, an expectation which may frequently be fraught with disappointment. N. W. Jones[1] reports his experience with the Einhorn duodenal bucket as follows: "This much I may say for the Einhorn test: In over thirty selected cases in which I have used it it has not been of any value in a single instance. Its findings are accidental and inconstant. In freshly bleeding pyloric ulcers it has been entirely negative, and again in the stomachs of comparatively healthy people blood stains have been obtained."

My method consists in letting the patient swallow the duodental tube devised by me[2] beyond the 60 cm. mark. This will cover the first third of the pars duodenale horizontalis superior, the most frequent site of the ulcer. I then remove the duodenal contents by aspiration. In four out of six suspected cases examined for duodenal ulcer I have found minimal but macroscopically visible blood particles floating on the duodenal contents[3] which, taken from the part mentioned, were still mixed with gastric contents. In the deeper parts of the duodenum the blood traces gradually disappear. In connection with these unmistakable findings the patients experience a slight susceptibility at the place where the tube rests in the duodenum, both during and a short time after the examination. Blowing into the tube is felt by nearly all patients, though not painfully, and, owing to the fact that the insufflathis experiment may likewise be utilized for determining the position of the duodenum. Pronounced sensibility in this respect, however, I have not found in any one of the special examinations, numbering over one hundred, made with the duodenal tube. This susceptibility, as well as the minute hemorrhage, observed in my cases disappears after proper ulcus treatment. In my opinion this disappearance may be regarded as a sufficient proof of the effected healing of a previously existing duodenal ulcer. In conclusion I may single out and describe one of the four observed cases.

H. K., thirty-eight, married, teacher, of moderate habits, had pneumonia at the age of seventeen. Has had "stomach trouble" for two years, pyrosis, acid eructations, occasionally violent spasms, especially after ingestion of certain articles of food; no vomiting. Appetite always good; constipation always present as long as he could remember. No material loss in weight. Six months ago he was bedridden for two weeks owing to violent "abdominal spasms," during which time he vomited several times. He never felt quite well since. I saw the patient for the first time August 13, 1910. Patient complained during the last few days of increased pain in the epigastrium, with radiation upward to the right, the painful paroxysms occurring with a certain regularity toward 10 o'clock in the morning and about 5 o'clock in the afternoon, sometimes in the middle of the night. When he purposely brings on vomiting there is relief, and this is also the case after ingestion of a little warm milk. By hammer percussion it is possible to distinctly demarcate a small area to the right of the parasternal line, corresponding to the position of the duodenum. The superimposed rigid muscle prevents deeper palpation. The same morning the stomach tube was introduced at random, 1½ hours after the ingestion of a glass of milk, "surprise test," and aspiration brought up watery matter mixed with slight food remnants (light stagnation). Congo +, free hydrochloric acid 30, total acidity 50, no blood. August 14, 1910: Empty stomach; about 3 ounces of gastric contents mixed with little food remnants. Congo +, no blood. Microscopic: starch, yeast cells, myelin, numerous epithelia. August 16, 1910: Ewald's testmeal. Well emulsified, little mucus, distinct hypersecretion, free hydrochloric acid 70, total acidity 90, no blood. August 20, 1910: Introduced duodenal tube half an hour after the ingestion of 250 c.c. of "test-milk" (half milk and half water) down to the 65 cm. mark. Aspiration 20 minutes after insertion. Contents of very light green color, suspended milk casein. Congo +, and above all a few blood dots observable; the presence of blood can also be demonstrated chemically. At a depth of 70 cm., as marked by the tube, 35 minutes after insertion, the contents were clear, light green, fluorescent, alkaline, no blood traces. Otherwise the examination of the duodenal contents showed approximately normal conditions. Specific gravity 10053, steapsin clearly present, trypsin present, amylopsin considerable traces, mucin above 5 per cent. Following the examination duodenal lavage with bismuth (15 to 250) was instituted. The patient was now subjected to rigorous ulcus treatment. The duodenal tube was inserted a second time twelve days after the first introduction. There was no blood, and the susceptibility for the tube had almost completely disappeared. Bismuth lavage. There have been no subjective complaints from the end of the third week to the present time.

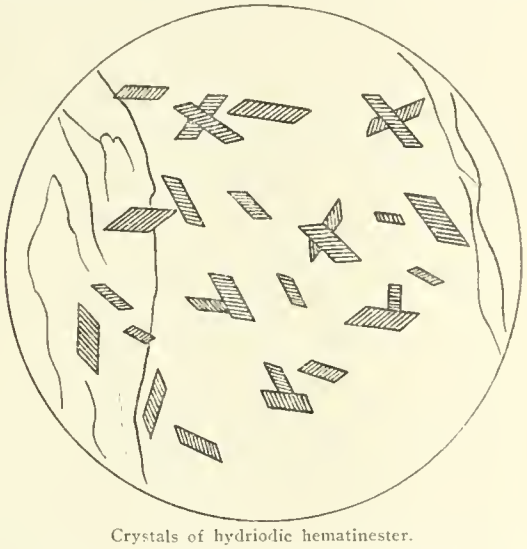
The idea might suggest itself that this was a case of trauma occasioned by the small ball attached to the end of the tube, but this is contradicted, first, by the absence of similar findings in my numerous other examinations of the duodenal contents; second, by the impossibility of causing a lesion owing to the fact that the small silver ball is enveloped on all sides by the soft tube; this must of necessity produce a slighter interference than the insertion of the much stiffer stomach tube. I therefore consider this new symptom, even if it be the only one present, an unmistakable sign of the presence of duodenal ulcer.

I have had occasion to observe eight further cases suspected of ulcus ventriculi, and to find my above results fully corroborated. In these cases, too, there were the characteristic clinical symptoms: "painful dyspepsia," which had existed for years, interrupted by violent attacks of so-called "hunger-pain"; regurgitation, rarely vomiting, of acid masses; abatement of these symptoms after ingestion of food or alkalis; usually hyperchlorhydria and hypersecretion. Gastric irrigations in stagnations, bland, semifluid diet, and alkalis have always been followed by prompt and favorable results, not only removing the pain and stagnation in a short time, but also relieving the pylorospasms, a fact of which I have been able to convince myself by the increased facility with which my duodenal tube could now be introduced.

The diagnosis of "pyloric spasms" is rather uncertain. The question of the existence of "idiopathic" spastic contractures of the pylorus is by no means definitely decided. If they should exist, pylorospasms alone would not lead to stenotic manifestations according to the experience of Schuetz and my own. On the other hand, organic processes of the pylorus cannot always be excluded. Nor would it be feasible to completely identify the two ostia of the stomach which perform totally different functions and are subject to somewhat different affections. It would, therefore, not be an easy matter to decide upon mechanical interference with the pyloric ostium by way of analogy. The "stretching" of the pylorus, as is done by Einhorn, constitutes mechanical interference in the dark. Even theoretically this mechanical interference would not be justified, because favorable results could only be expected by a more "permanent stretching" of a definite place—the affetced part, which would be an impossible proceeding from purely technical considerations. I therefore have advised and am using a "valve arrangement" in the leading ball of my duodenal tube. By means of this modification we are

able to insufflate and aspirate just as well; although I do not use this modified tube for "dilating" purposes.

In all my eight new cases I have found the above described macroscopically visible, little blood points floating on the fluid which had been aspirated from the duodenum. But the local susceptibility to the duodenal tube, which I have described above, does not seem to be equally constant in all cases, since I succeeded only in four of my eight new cases in finding the same clearly established. A further new experience consists in the fact that, in spite of the macroscopically visible little blood points, a chemical examination for blood was in most cases negative. Lyle and Kober called my attention to the probable cause of this remarkable fact, they being of the opinion that a series of so-called "inhibitors" were responsible for the same, which would interfere with the ordinary chemical blood examination, but the nature of which would yet have to be discovered. Where the aloin and guaiac tests failed I was in one case able to obtain a positive result with the benzidin test, which I applied in accordance with a modification personally communicated to me by Paul Cohnheim. The method is as follows: Place a little benzidin powder (Merck) in a dry test tube and shake it up with about ½ c.c. of glacial acetic acid; add 2 c.c. of H_2O_2; then carefully place on the surface the fluid which has to be examined and which has previously been boiled. The green tint of the resulting ring permits also of certain quantitative conclusions to be drawn.



Crystals of hydriodic hematinester.

The phenolphthalein test for blood, mentioned first by I. H. Kastle,[4] more recently tested by Lyle, and modified by Boas,[5] seems to be destined to supplant all other blood tests, owing to its certainty, rapidity, and keeping qualities of the solution. But in order to positively convince myself whether the floating little points were really blood I applied the microchemical method (Teichmann's hemin crystals), using an easy modification introduced by Stozyzowski.[6] One of the little blood points, if possible without any duodenal admixture, is placed on a slide, slightly dried, and covered with a small cover glass. At the margin of the latter 1 to 2 drops of the following mixture is placed: Alcohol, water, glacial acetic acid, of each 1 c.c., and 3 drops of hydriodic acid (if possible undecomposed, of a specific gravity of 1.5). The specimen, being surrounded by this solution, is boiled for about ten seconds over a small spirit flame, which should be so small as to be hardly visible. The loss sustained by evaporation should be constantly replaced. The preparation is best inspected by objective 7, ocular 3. If the little particle is blood there will be found numerous rhomboid prismatic crystals of a blackish color (see cut), which consist of hydriodic hematinester.

Since the blood findings just described are seen with great constancy in cases suspected of duodenal ulcer, while they are practically never present in all the other cases, I am ready to assert once more that even in cases where the clinical symptoms are not very pronounced the positive blood findings may be a sufficient proof of a pyloric ulcer. On the other hand, one solitary negative blood test would not definitely exclude the presence of a momentarily not bleeding or incompletely healed ulcer.

REACTIONS TO TUBERCULIN.*

By LOUIS C. ROUGLIN, M.D.,
ATLANTA, GEORGIA.

The subject of this paper will be confined to such reactions only as occur as a result of tuberculin used for therapeutic purposes and will not take into consideration nor give any description of the purely local reactions that occur as a result of the local tuberculin tests as the ophthalmic, Morro, or von Pirquet.

At the present time we have three methods of giving the tuberculin for therapeutic purposes: Wright's, or the opsonic index method; the reaction method and the tolerance method. Wright's method, based upon the value of opsonic immunity in general produces neither reaction nor toxic tolerance—two of the most important factors in the conception of tuberculin immunity of to-day—and later studies have proved the opsonic index as a guide to the interval of dosage inaccurate and impracticable, so that from our present conception of tuberculin therapy, this method must, at least, for the present, be superseded by the reaction and tolerance method.

Sahli and Denys consider the highest degree of toxic tolerance as the only object to be gained, while Trudeau, White, Graham, Van Norman and Klebs believe that mild reactions are of value, but in the absence of any definite means of control, toxin tolerance is the safest and best method of tuberculin treatment. By this method the initial dose is very small—far below that expected to produce reactions—the interval and increase of doses being regulated by condition of the patient, the physician being guided by the tolerance of the previous dose as manifested by the patient's condition.

From the above it is manifestly evident that the study and recognition of reactions in tuberculin treatment is of the utmost importance to the phthisiotherapist, as this is his only guide at present indicative of tolerance, and Lebor has proven that the greatest production of antibodies occurs from reaction dosage of tuberculin and little or no production of antibodies from smaller doses.

*Read before the Fifth Congressional District Medical Society December 17, 1910.

Definition.—A tuberculin reaction may be considered any subjective or objective change occurring in the condition of a tuberculous patient as a result of a tuberculin injection, provided such change of condition is not due to other causes.

Causes of Reaction.—The cause of the tuberculin reaction has not been fully explained by any of the theories yet propounded. Koch first promulgated the idea that tuberculin caused the death of the cells composing the tubercle; Buchner considered it due to a "latent fever instability" existing in tuberculous subjects; Hueppe considered it as the normal disease process freshly excited by tuberculin; Liebmann considers chemotaxis as an explanation of the local reaction; Arloing assumed the tubercle to be weakened by tuberculin, permitting the poison to escape and thus causing a general reaction; Kohler and Westphal held that tuberculin formed a new compound with the products of the bacilli initiating the tubercle; Klebs considered that tuberculin exerted a transforming action on the tubercle tissue, restoring it to normal conditions. Owing to the discovery of agglutination or precipitation phenomena in tuberculous serum, Behring thinks that the smallest arterioles near the tubercles secrete antibodies (precipitins), causing intravascular coagulation by encountering the toxin as soon as the antibodies appear. This leads to extravasations and other phenomena of the local reaction. The general reaction is less specific and due to free toxin. In favor of this explanation is the gradual return of tuberculin reaction susceptibility after the cessation of injection and the accompanying decrease in precipitation power. Whether or not there is always a slight increase in toxin absorption from the foci, due to more rapid blood or lymph flow, is not known, as the fever is not infrequently obtained from a small dose of tuberculin without evidence of local disturbance. The reason for this susceptibility and its relation to tuberculin is not yet fully understood. Klebs assumes that the tuberculin acts as an "enzymogen" which in time sets free from the cells about the tubercle sufficient toxin of digested tubercle baccilli to produce the reaction.

It is perhaps due to the introduction into the system of a foreign toxin, although of a similar nature, but not attuned to the condition of the system, which excites by its intrusion an increased activity and irritability of the toxin already attuned to or tolerated by the system, this excitability producing an increased amount of antibodies (agglutinin and precipitins), also more or less toxic absorption, hence the fever. This would explain why tuberculin would prove injurious to an acute case already overwhelmed by toxin and also explain the irritability of the mucous membrane to tuberculin as manifested by local reactions.

Tuberculin reaction may be purely local, as manifesting itself by increased congestion of the part, as in lupus, laryngeal tuberculosis, or tuberculosis of the eye or at the site of injection, manifesting itself by the usual local sings of inflammation, such as heat, redness, swelling, etc. More or less local pain is always present in local reaction.

The reaction may be general, manifesting itself by any or all of the following symptoms: Headache, pain in the limbs and joints, malaise, faintness, giddiness, insomnia, drowsiness, fatigue, nervousness, vomiting, chilliness, fever blisters, enlargement of glands, rash, increased cough and expectoration, hemorrhage, pleurisy, shortness of breath, loss of strength and weight, loss of appetite, rapid pulse, etc.

A typical reaction usually occurs from eight to twenty hours after the injection. The patient begins to feel feverish, sometimes chilly, or a marked chill may usher in the reaction followed by fever, patient feeling heavy and dull, experiencing lassitude, and seeking his bed. All symptoms become rapidly aggravated, pain occurring in the back, legs and head, often very severe, oppression is felt in the chest, cough and expectoration become increased, fever rises to 103° or even 105°, and the patient may even be delirious—the symptoms resembling a severe case of grip. These symptoms usually persist from eight to twelve hours, the next day the patient feeling a little weak, otherwise all right.

In nervous persons the reaction may occur within two or three hours after the injection. In one of my cases, in a nervous young girl, a sharp reaction occurred on a few occasions within two hours and even less after the injection of tuberculin. Her temperature would rise to 103° or more, followed by all the usual symptoms, all of which would entirely disappear in the course of four to six hours.

A reaction may be mild, the patient not feeling sick enough to go to bed, temperature not going over 100°; diarrhea or constipation is common with mild reactions. A reaction may be delayed from sixty hours to eight days, occurring then with all the severity of a sharp reaction. In these cases an increased pulse rate may usually be detected before the onset of the reaction proper.

Rash occurs only after severe reactions and may be nothing more than the ordinary fever blisters, but may simulate any of the exanthema. In one case a rash appeared which had every appearance of smallpox, but disappeared entirely within three days.

Any of these conditions may occur without any appreciable rise in temperature, and so must be considered as a much more delicate and earlier indication than fever. The pulse rate usually corresponds to the temperature, and no more stress should be laid upon it than on fever. Neuralgias are common, and in cases where the teeth are bad, toothache is a very painful as well as an annoying complication.

Reaction should be avoided, but under our best present method of administering tuberculin, unless every precaution, watchfulness and diligence is used severe reactions are bound to occur; and their careful study, observation, and early recognition is of the utmost importance to the welfare of the patient, to the physician, and to the proper administration of tuberculin.

757-758 Candler Annex.

Radiotherapeutic Treatment of Angiomata.—E. Albert-Weil advocates the treatment of all angiomata by means of the *x*-rays. He finds that all kinds of angiomata may be cured by this means, whether they be raised above the skin, or depressed with deeply seated prolongations, or mere port wine stains. For the red marks are substituted white marks that are much less noticeable. It is necessary to produce an inflammation in order to remove the growth, but the surrounding skin should be protected by lead shields. Hard tubes are to be used and the full strength of rays, alternating with irradiations with an aluminum shield in place. The author has obtained a cure in fifteen cases of angioma by these applications.—*Paris Médical.*

DR. FINLAY AND THE YELLOW FEVER MOSQUITO.

ON August 14, 1881, Dr. Carlos J. Finlay, a Scotch physician practising in Havana, read a paper before the Royal Academy of that city in which he propounded the novel theory that yellow fever was propagated through the agency of mosquitos. Naturally, a proposition so at variance with the popular and professional belief in fomites was received with incredulity, and the author of the new theory was the object of more or less good natured ridicule. Nothing daunted, however, with true grit he continued his observations on the remarkable coincidence between the prevalence of yellow fever and the temporary increase in the numbers of mosquitos; studied the anatomy, the manner of breeding, and the habits of the mosquitos, and also continued his inoculation experiments. These were begun in July, 1881, at which time he "obtained a well marked attack of yellow fever following a bite by a contaminated mosquito." In a paper published in the *American Journal of the Medical Sciences* in October, 1886, Finlay described the mosquito which he regarded as the agent in the spread of yellow fever. It had a dark-colored body with ventral surface coated with thick skin and marked with gray or white rings; on each side of the abdomen was a double row of white spots; its most striking feature was five white rings on the hind legs, present but less marked on the anterior and middle legs; white spots were visible on the sides of the thorax and front of the head, while the corselet presented a combination of white lines in the figure of a two-stringed lyre; the wings when closed did not cover the body. The female laid her eggs singly—not in a boat-shaped aggregate like the night mosquito. It was diurnal and crepuscular in its habits, flying and biting early in the morning, between 9 and 10 A.M., and in the afternoon until night. It was called *Culex mosquito* and later *Culex fasciatus,* and was the same mosquito that was afterward named *Stegomyia fasciata,* and is now known as *Stegomyia calopus*—the yellow-fever mosquito.

In the same article Finlay argues with much acuteness in support of his theory, and he concludes with the following passage, which we quote at length since it sets forth so clearly the views as to the spread of yellow fever that are universally held to-day: "From the evidence adduced in the preceding pages," he writes, "I conclude that while yellow fever is incapable of propagation by its own unaided efforts, it may be artificially communicated by inoculation, and only becomes epidemic when such inoculation can be verified by some external natural agent, such as the mosquito. The history and etiology of yellow fever exclude from our consideration, as possible agents of transmission, other blood-sucking insects, such as fleas, etc., the habits and geographical distribution of which in no wise agree with the course of that disease; whereas a careful study of the habits and natural history of the mosquito shows a remarkable agreement with the circumstances that favor or impede the transmission of yellow fever. So far as my information goes, this disease appears incapable of propagation wherever tropical mosquitos do not or are not likely to exist, ceasing to be epidemic at the same limits of temperature and altitude which are incompatible with the functional activity of those insects; while, on the other hand, it spreads readily wherever they abound. From these considerations, taken in connection with my successful attempts in producing experimental yellow fever by means of the mosquito's sting, it is to be inferred that these insects are the habitual agents of its transmission."

The mosquito theory is again set forth with all detail in an article running through several numbers of the *Edinburgh Medical Journal* in 1894, and in a paper published in the MEDICAL RECORD, May 27, 1899, before the U. S. Army Commission had taken up the work which proved the correctness of Finlay's theory beyond the possibility of denial, he thus foreshadows the measures necessary to exterminate the disease and prevent its recurrence. "Why," he says, "should not the houses in yellow fever countries be provided with mosquito-blinds, such as are used in the United States as a matter of comfort, while here it might be a question of life or death? The mosquito larvæ might be destroyed in swamps, pools, privies, sinks, street sewers, and other stagnant waters in which they are bred, by a methodical use of potassium permanganate or other such substances, in order to lessen the abundance of mosquitos; but the most essential point must be to prevent those insects from reaching yellow fever patients, and to secure a proper disinfection of all suspicious discharges, in order to forestall the contamination of those insects. Well ventilated hospitals should be built upon high grounds, with no stagnant waters nor marshes in their vicinity; doors and windows protected by mosquito blinds; a good system of drainage and sewerage; and facilities for destroying any mosquitos or larvæ which might be found within the building. Only the upper stories should be occupied by the sick, and none but yellow fever patients and such malaria patients as are considered immune against yellow fever should be admitted. The examination for admission might be carried out in a separate building, and a separate department devoted to the suspicious cases under observation. With such hospitals at hand, and an efficient board of health that would see to the

proper arrangements for patients who could be left at their homes, and general sanitary improvements within and around the principal cities, there can be no doubt that yellow fever might be stamped out from Cuba and Porto Rico, and malaria reduced to a minimum. It would then be the business of the port and quarantine officers to prevent the introduction of fresh germs."

When the United States Army occupied Havana, Finlay saw his opportunity and went to the sanitary authorities with his mosquito and his theory and urged them to investigate the subject and prove the theory which he knew to be a fact. He was received with polite toleration, but without great enthusiasm. He persisted nevertheless in season and out of season, and in fact made such a nuisance of himself that an investigation was finally decided upon, his confidence arousing a suspicion that he might, after all, be on the right track. The results of this investigation are well known. Major Reed and his associates, Agramonte, Carroll, and Lazear, took Finlay's mosquito and his data and by a series of experiments, the equal of any in the annals of scientific investigation, established beyond cavil the mosquito doctrine of yellow fever transmission. Some of his views were shown to be erroneous, which is not surprising when one considers the disadvantages under which he labored single-handed, but his basic idea was found to be absolutely correct. Making a practical application of this doctrine, and perfecting the measures outlined by Finlay in his MEDICAL RECORD article, the genius of Gorgas converted the two notorious pestholes, Havana and Panama, into health resorts.

This is all ancient history, but for that very reason it is in danger of being forgotten. Even such a master of medical history as Osler forgot it in an address on the transmission of disease through the agency of blood-sucking insects, which he delivered before the London School of Tropical Medicine last spring. In this address he omitted all mention of Finlay's work, and only when he was reminded of it by a letter from Guiteras of Havana in the *Lancet* did he apparently recall the great part which this pioneer had taken in the establishment of the mosquito doctrine. We would not in the least belittle the brilliant experimental work of Reed and his associates or the practical application of the results made by Gorgas, which is the admiration of the world, but in the interest of truth and as a matter of pure justice to the originator of the theory, credit and full credit should be given to Finlay. Reed himself would have been the last to refuse such credit, and indeed he did acknowledge freely the debt which mankind owes this acute observer. In an article on "The Propagation of Yellow Fever," published in the MEDICAL RECORD, August 10, 1901, Major Reed generously says: "To. Dr. C. J. Finlay of Havana must be given full credit, however, for the theory of the propagation of yellow fever by means of the mosquito, which he proposed in a paper read before the Royal Academy in that city on August 14, 1881. From that date to the present time, Finlay has made a number of valuable contributions to the origin and mode of transmission and the prevention of yellow fever." The MEDICAL RECORD has always, from the time it first called attention to the theory in January, 1884, to the present time, acknowledged Finlay as the originator and, short of indisputable scientific demonstration, the prover of the theory of the transmission of yellow fever through the agency of the mosquito. In common with all Americans we are proud of the achievement of Reed and his associates and of Gorgas, for without their labors yellow fever would in all probability still be the curse of Havana, and the Panama Canal would be naught but the mosquito-breeding ditch abandoned by the French twenty years ago; but it may be doubted whether their work would even yet have been done—it certainly would not have been done so soon—had not the way been pointed out by Charles J. Finlay.

PATHOLOGICAL DOCUMENTS FROM ANTIQUITY.

PROGRESS is still possible in this direction, despite the fact that prehistoric skeletons have long been preserved in medical museums, while at least sixty years ago mummies were eagerly studied with the microscope. The subject of the antiquity of this or that affection was long ago seized upon by the copy-maker, and we have had numerous monographs written *pro* and *con* as to the antiquity of syphilis and leprosy, which by their very controversial quality have readily made converts among those who do not care to hear both sides. Why matters of this sort should be treated polemically is incomprehensible. The writers on such themes as the antiquity of a given disease should by rights not traverse the domain of facts and should leave the matter of personal opinion to the reader. Yet such noncommittal writing evidently does not make good copy and is not in demand with the public.

At a recent meeting of the Leipzig Medical Society (*Münchener medizinische Wochenschrift*, March 7) Sudhoff covered the entire subject of ancient pathology as revealed by household utensils and other commemoratives preserved in stone or clay, and in the progress of our knowledge of actual human survivals—bones, mummies, etc. His work is largely confined to Egypt and Asia Minor. He seems to express a deep-seated contempt toward recent writers who have made of syphilis an American disease pure and simple, but touches only lightly on this subject. He states that at least 10,000 mummies have now been examined, and that with such large material nearly every tissue in the body is accessible to histological studies.

As a result it is discovered that all kinds of concretions were common among the old Egyptians, including biliary, renal, vesical, and salivary calculi —also arteriosclerosis and aneurysm. Osteoarthritis of a deforming character seems to have been very common, and was, perhaps, connected with the rise and fall of the Nile, which necessitated much wading, etc. The same affection is common to-day. Tuberculous bone and joint disease seems to have been common. Although dental caries *per se* was evidently rare, ulcerated teeth were often in evi-

dence as a result of attrition. No evidence whatever is found of leprosy in old Egypt, a most striking fact, for the disease is believed by many to have originated there. The absence of any traces of it would seem to be confirmatory of the opinion that the leprosy of the Bible was a totally different disease from the affection called by that name today.

The Health Officer of the Port.

The term of service of Dr. Alvah H. Doty as chief quarantine officer of the port of New York expired several weeks ago, and it is probable that his successor will soon be appointed. The names of a number of aspirants to the position have been mentioned, but the Governor should have little trouble in selecting the right man, for however worthy the other candidates may be, none is so qualified by experience and proved capability as Dr. Doty himself. The office is one of enormous responsibility, since the man who fills it is charged with the protection not only of this city but of the entire country from the invasion of epidemic diseases. Smallpox, cholera, cerebrospinal meningitis, the plague, and other scourges are ever knocking at our door, and the slightest error of judgment or relaxation of vigilance on the part of the quarantine officer might result in an epidemic costing hundreds of lives and the loss of millions of dollars to the commerce of the port. No man, however capable and earnest he might be, could be free from the chance of error of judgment, lacking experience, and there is none who has had the experience of the present quarantine officer. It is nearly as essential that commerce be not interfered with by the unnecessary detention of a ship as it is that the health of the community be not endangered by the passing of a ship with epidemic disease among its passengers, and an inexperienced quarantine official might work almost as much harm by excess of zeal as by lack of vigilance. Dr. Doty has won the unanimous approval not only of the sanitary authorities but of the importers and the steamship companies as well, and they would all view the appointment of any other man as health officer of the port with great misgiving. We do not know that he is willing to continue in this arduous position, but it is his duty to do so, the city needs his services and the nation needs them, and we hope the Governor will, in his wisdom, see the expediency and the necessity of ignoring political considerations and of appointing Dr. Doty to succeed himself as chief quarantine officer of the port of New York.

Arteriosclerotic Myalgia.

Painful muscular cramps occur at almost all ages and under a wide range of circumstances, so that hardly any one is immune to them. They may be produced almost at will by overflexion or overextension of the limbs—in a word, by excessive contraction of certain muscles. They occur especially in the anemic and in fatigued states. Even the general public attributes muscular cramps to poor circulation, which may mean almost anything—for example, a spasm of the arterioles of the muscle. A score of years ago, if a physician complained of a muscular cramp, a colleague would jestingly feel of his pulse to see if arterial rigidity was present. He would perhaps add, "that is the latest," referring to the tendency of the period to make arteriosclerosis the sum and substance of pathology. At a meeting of the Dresden Society for Science and Medicine held recently (*Deutsche medizinische Wochenschrift*, February 23) Rohde discussed the subject of arteriosclerotic muscular pains. The same dualism that prevades all arterial pathology is present here. In addition to marked structural changes in the vessels, a functional spasm is superadded. We see a structural and functional type of intermittent limp, for example, and both may be conjoined in a single case. There are structural and functional types of stenocardia, and the two may occur in a single subject. There are structural and functional types of Raynaud's disease. Rohde's paper is not speculative in character, but is devoted to showing what cases of muscular cramp may be set down to arteriosclerosis and how these may be relieved. It is especially worth noting that in these cases the diagnosis is often, if not invariably, made by the nature of the palliative remedy. For example, if a cramp is present, involving a vasomotor spasm, the blood-pressure is raised, while nitrites relieve the spasm and the pain and lower the blood-pressure. There is nothing here to show the nature of the process; but in the elderly, arteriosclerosis is to be suspected, and this suspicion may be readily confirmed or at least justified by a careful examination of the patient. Cramps alone, however, do not warrant a diagnosis of arteriosclerosis. If these cramps constitute a distressing feature the patient is placed in complete rest, dieted, and, in a word, given the benefit of all hygienic measures.

The Bayne Antivivisection Bill.

If we were under the dire necessity of giving support to either of the antivivisection bills now before the New York Legislature we would favor the Pollock rather than the Bayne bill, for the reason that an open enemy is preferable to a secret one. The framers of the Pollock bill are frankly opposed to animal experimentation and the bill is designed to put every restriction possible, short of absolute prohibition, upon it. The framers of the Bayne bill are ostensibly open-minded inquirers seeking the truth. But the real sentiments of those behind the measure are well known and no one with any knowledge of the facts can doubt as to what the finding of the necessarily partisan committee of investigators would be. The expenses of the inquiry are to be met, not by the State but by private individuals or societies. The money will not be contributed by those already convinced of the value of animal experimentation, but will of course be supplied by the antivivisectionists. The commission will therefore be in the employ of fanatics, and will naturally start with a bias in favor of those whose money they are spending. But even if they were so superhuman as to see things as they really are and to report that there was no cruelty in the practice of animal experimentation, the principle would remain bad. As well might the Christian Scientists demand the passage of a bill for an investigation of hospital surgeons in order to determine whether their operations are justifiable. There are malpractice laws and there are laws preventing cruelty to animals. If surgeons cut up their patients unnecessarily they are answerable to the malpractice laws; if experimenters inflict cruelty upon animals they can be punished by the existent laws. The Bayne bill should be defeated. It is pernicious.

News of the Week.

Civil Service Examination.—The United States Civil Service Commission announces an examination on June 7, 1911, to secure eligibles from which to fill a vacancy in the position of medical interne in the Government Hospital for the Insane, Washington, D. C., at $600 per annum with maintenance. As considerable difficulty has been experienced in filling vacancies in the position of medical interne in the Hospital Service during the past few years owing to the limited number of eligibles available, qualified persons are urged to enter this examination. Further particulars may be obtained from the United States Civil Service Commission, Washington, D. C.

The Marie Feodorovna Prizes.—The American Red Cross announces that the Marie Feodorovna prizes will be awarded at the time of the International Conference of the Red Cross which will be held at Washington, D. C., in May, 1912. These prizes represent the interest on a fund of 100,000 rubles which the Dowager Empress of Russia established some ten years ago for the purpose of diminishing the sufferings of the sick and wounded in war. Prizes are awarded at intervals of five years, and this is the second occasion of this character. These prizes in 1912 will be as follows: One of 6,000 rubles; two of 3,000 rubles each; six of 1,000 rubles each. The subjects decided upon for the competition are: (1) Organization of evacuation methods for wounded on the battlefield, involving as much economy as possible in bearers. (2) Surgeon's portable lavatories for war. (3) Methods of applying dressings at aid stations and in ambulances. (4) Wheeled stretchers. (5) Support for a stretcher on the back of a mule. (6) Easily portable folding stretcher. (7) Transport of wounded between men-of-war and hospital vessels, and the coast. (8) The best method of heating railroad cars by a system independent of steam from the locomotive. (9) The best model of a portable Roentgen-ray apparatus, permitting utilization of *x*-rays on the battlefield and at the first aid stations. It rests with the jury of award how the prizes will be allotted in respect to the various subjects. That is to say, the largest prize will be awarded for the best solution of any question irrespective of what the question may be. Further information may be obtained by addressing Major Charles Lynch, Medical Corps, U. S. A., Chairman Exhibit Committee, American Red Cross, Washington, D. C.

Deaths from Diarrheal Diseases.—During the first three months of 1911 there were 508 deaths due to intestinal disorders among the children in New York City, as compared with 348 for the corresponding period of 1910. An investigation by the Department of Health shows that this large increase occurred almost entirely among the children in institutions. In Manhattan Borough, for example, there were, during the first three months of 1910, 77 such deaths reported from institutions and 129 from private families, while during the same time in 1911 there were 200 deaths in institutions and 127 in private families. Of the 200 deaths, 86 occurred in the New York Foundling Hospital, the children in which are of course practically all of low vitality.

Spitting Nuisance.—The Board of Health has recently had made a tabulation of the number of arrests, and the disposition of the causes, for violation of the section of the Sanitary Code prohibiting spitting in public places. The figures are as follows:

	Manhattan.	Brooklyn.	Bronx.	Queens.	Richmond.	Total.
Arrests	171	153	73	27	10	434
Fined	137	59	61	22	..	279
Discharged	32	..	12	..	..	44
Sentence suspended	2	94	..	5	10	111
Amt. of fines	$166	$79	$142	$27	..	$414

Endorse Action of Health Board.—At a meeting of the New York Urological Society, held at the Academy of Medicine on April 5, a resolution was passed endorsing the action of the New York City Board of Health declaring the sanitary control of venereal diseases to be necessary for the protection of the public health, and directing its Medical Advisory Board to formulate a definite and comprehensive plan for the control of these diseases.

Gifts to Charities.—By the will of the late Mr. Bernard G. Amend the German Hospital in this city receives a bequest of $2,000.

The Methodist Episcopal Hospital of Brooklyn receives $5,000 under the will of the late Wr. William A. Lawrence of Goshen, N. Y.

A jury in the Supreme Court on April 11 returned a verdict sustaining the will of the late Edward O. Kindberg of New York by which his residuary estate, about $100,000, was left to the Presbyterian Hospital. A later will in which the hospital was not mentioned was declared invalid on the ground that the testator lacked testamentary caapcity when it was signed.

Mount Sinai Hospital, New York, receives a bequest of $500 under the will of the late Max Jacoby, who died on April 8.

A number of charitable institution are beneficiaries under the will of the late Samuel Meyers of New York. Among them the Ellis Hospital, the Physicians' Hospital, and the Children's Day Nursery of Syracuse, and the Hebrew Orphan Asylum of New York receive $5,000 each.

The Supreme Court of Missouri recently rendered a decision upholding the will of the late Robert A. Barnes of St. Louis, by which a sum of about $3,000,000 was set aside for the erection, maintenance, and endowment of a nonsectarian hospital in St. Louis.

The Mount Zion Hospital of San Francisco has received a gift of $20,000 toward its building fund from Mrs. M. S. Grinbaum as a memorial to her husband, and also a gift of $100,000 for the same purpose from Mr. I. W. Hellman.

Sale of Red Cross Seals.—The State Charities Aid Association announces that by this year's sale of seals in the State, outside of New York City and Buffalo, $31,160 has been raised for the antituberculosis work. This is $9,500 more than was raised in the same territory last year.

Plague at Caracas.—The State Department at Washington was advised on April 13 of the appearance of a case of bubonic plague at Caracas, Venezuela.

Notable Patients.—Dr. Lewellys F. Barker, professor of medicine in Johns Hopkins University, Baltimore, underwent an operation for appendicitis at the University Hospital on April 10. Dr. Henry Clarke Coe of New York, professor of gynecology in the Bellevue Hospital Medical School, was operated on for the same disease on April 6. The latest reports in both cases promised speedy recoveries.

Against Bronx Hospital.—The New York State Board of Charities at a recent meeting disap-

proved the articles of incorporation of the Bronx Hospital which Dr. Abraham Jacobi and a number of his associates proposed to establish in that borough. The plan had met with considerable opposition from certain physicians of the Bronx, who considered it as an invasion of their territory by Manhattan doctors.

Fresh Aid in Tuberculosis Fight.—Mr. James A. Patten of Chicago by a generous gift to the Northwestern University has made possible the establishment of a new chair in the Medical Department of the University to be known as the Chair of Experimental or Research Medicine. It is understood that the first concern of the new department will be an investigation having for its aim the discovery of a cure for tuberculosis.

Rush to Sell Blood.—A short notice in the New York newspapers stating that the Har Moriah Hospital would give $25 to the man who would submit to an operation for blood transfusion to save the life of a patient in the institution brought forth an unexpected response, over 100 candidates presenting themselves long before the hour set. As the suitability for such an operation is usually in inverse proportion to the need for $25, most of the applicants were rejected after a superficial examination; but one was finally selected for the operation, which was successfully performed. The patient, a woman suffering from purpura hæmorrhagica, was reported as greatly improved.

The American Society of Sanitary and Moral Prophylaxis.—A meeting of this society will be held in connection with the regular meeting of the New York County Medical Society at the Academy of Medicine, Monday evening, April 24, at 8.30 P.M. The general subject for discussion will be: "The Health Department Control of Venereal Diseases."

Deutsche Gesellschaft für Urologie.—The appointment of Dr. Victor Blum as secretary of the German Urological Society, in place of the late Dr. Kapsammer, is announced. All correspondence relating to the next congress should be addressed to Dr. Blum at Wien, VIII, Alserstrasse 43.

Canadian Medical Association.—The annual meeting will be held in the building of the Medical Faculty of McGill University, Montreal, on June 7, 8, and 9, 1911. The Section of Medicine will include a symposium on acute poliomyelitis, and, in connection with the Section of Preventive Medicine, a discussion on water supply and its relation to disease. Dr. Edward Archibald of 160 Metcalfe street, Montreal, is the general secretary of the association.

American Proctologic Society.—The thirteenth annual meeting of the society will be held in Los Angeles, Cal., at the Hotel Alexandria, on June 26 and 27, 1911, under the presidency of Dr. George J. Cook of Indianapolis, Ind. The secretary of the society is Dr. Lewis H. Adler, Jr., of Philadelphia.

The Fifteenth International Congress on Hygiene and Demography will be held at Washington, D. C., on September 23 to 28, 1912, by invitation of the President of the United States which was authorized by a joint resolution of Congress passed in February, 1907. The Governor of each State also has been officially invited to participate in the Congress. The Congress is divided into nine sections: I. Hygienic Microbiology and Parasitology; II. Dietetic Hygiene; Hygienic Physiology; III. Hygiene of Infancy and Childhood; School Hygiene; IV. Industrial and Occupational Hygiene; V. Control of Infectious Diseases; VI. State and Municipal Hygiene; VII. Hygiene of Traffic and Transportation; VIII. Tropical, Military, and Naval Hygiene; IX. Demography. Active membership in the Congress is open to persons interested in public health or vital statistics upon payment of a fee of $5.00. Inquiries and application for membership should be made to the Secretary-General of the Fifteenth International Congress on Hygiene and Demography, Army Medical Museum, Washington, D. C.

Jewish Maternity Hospital.—The annual banquet of the medical staff of the hospital was held on Saturday, April 8, at Murray's Roman Gardens. Addresses were delivered by Dr. Clifton J. Edgar, Dr. Ralph Waldo, Dr. Howard Lilienthal, Dr. Abraham Mayer, Dr. Leopold Jaches, and others. Dr. Nathan Ratnoff acted as toastmaster.

Illinois State Hospitals Medical Association.—The first annual meeting of this association, which is composed of members of the medical staffs of the Illinois State Hospitals for the Insane and other State charitable institutions, was held at the Elgin State Hospital on April 12 and 13.

The Society of Ophthalmologist and Otologists of the District of Columbia gave its annual banquet at the Arlington Hotel, Washington, on April 8. The address of the evening was delivered by Dr. George E. de Schweinitz of Philadelphia.

Logan County (Arkansas) Medical Society.—At the annual meeting on April 5 the following officers were elected for the ensuing year: *President*, Dr. J. S. Shibley, Booneville; *Vice-President*, Dr. R. A. Haskins, Ratcliffe; *Secretary-Treasurer*, Dr. A. R. Hederick, Booneville.

Butler County (Nebraska) Medical Society.—The following officers were elected at the annual meeting held at David City on April 5: *President*, Dr. T. J. Vanderhoof, Rising City; *Vice-President*, Dr. E. D. Banghart, David City; *Secretary-Treasurer*, Dr. H. E. Marselue, Octavia.

Florence County (South Carolina) Medical Society.—At the annual meeting held in Florence on March 17, the following officers were elected: *President*, Dr. D. H. Smith; *Vice-President*, Dr. R. P. Covington; *Secretary*, Dr. W. S. Lynch of Scranton.

Tenth Councilor District (Arkansas) Medical Society.—The following officers were elected at the annual meeting held at Rogers, Ark., on March 21: *President*, Dr. John Young, Springdale; *Vice-President*, Dr. Epler, Fort Smith; *Secretary*, Dr. D. R. Dorente, Fort Smith; *Treasurer*, Dr. O. M. Bourland, Van Buren. The next meeting will be held at Fort Smith.

Titus County (Texas) Medical Society.—At the annual meeting, held at Mount Pleasant on March 23, the following officers were elected for the ensuing year: *President*, Dr. A. A. Smith, Talty; *Secretary*, Dr. W. H. Blythe, Mount Pleasant.

Edgefield County (South Carolina) Medical Society.—The following officers were elected at the annual meeting, held at Edgefield on March 29: *President*, Dr. Hunter of Trenton; *Vice-President*, Dr. George Walker of Johnston; *Secretary-Treasurer*, Dr. John G. Edwards of Edgefield; *Delegates to State Convention*, Dr. R. A. Marsh and Dr. S. Morrall.

American Medico-Psychological Association.—The sixty-seventh annual meeting will be held at the Brown Palace Hotel, Denver, Colorado, on

June 19 to 22, 1911, under the presidency of Dr. Charles W. Pilgrim of Poughkeepsie, New York. The program includes an interesting symposium on pellagra arranged by Dr. William A. White of Washington, D. C.

American Society for the Study of Alcohol and Other Narcotics.—The fortieth anniversary meeting will be held in Baltimore, Maryland, on April 19 and 20, 1911. This was the first medical society organized for the study of the drink and drug neurosis, its first meeting having been held in New York in 1870. Information regarding the meeting may be obtained from the secretary, Dr. T. D. Crothers, Hartford, Conn.

Obituary Notes.—Dr. Edward Patrick Stanley Hart of Jersey City, N. J., a graduate of the Long Island College Hospital, Brooklyn, in 1897, assisting visiting surgeon to St. Francis' Hospital, Jersey City, and a member of the New Jersey State and Hudson County Medical Societies, and the Physicians' and Surgeons' Club, died of pneumonia at his home, on April 10, aged 37 years.

Dr. Caine C. Godshaw of Louisville, Ky., a graduate of the Medical Department of the University of Louisville in 1874, died suddenly on April 3, from injuries accidentally received, aged 55 years.

Dr. William Edward Hibbard of Pasadena, Cal., a graduate of the New York University Medical College in 1889, and a member of the American Medical Association, the California and New York State Medical Societies, and the Los Angeles County Medical Society, died at his home as the result of an accident, on March 17, aged 47 years.

Dr. George C. Craig of Rock Island, Ill., a graduate of the Jefferson Medical College, Philadelphia, in 1869, a veteran of the Civil War, and a member of the American Medical Association and the Illinois State and Rock Island County Medical Societies, died at his home of pneumonia on March 12, aged 65 years.

Dr. Simon M. Brainin of New York, a graduate of the University of Dorpat, Russia, in 1881, and a member of the New York State and County Medical Societies, and of the German Medical Society, died at his home on March 31, after a long illness, aged 56 years.

Dr. Robert Rae of Portageville, New York, a graduate of the Medical Department of New York University in 1858, a member of the New York State and Wyoming County Medical Societies, and a veteran of the Civil War, died at his home on April 5, aged 78 years.

Dr. William C. Mason of Washington, D. C., a graduate of the Medical Department of Howard University, Washington, in 1886, died at his home after a short illness, on March 28.

Dr. Norman O. Greer, of St. Louis, Missouri, a graduate of the St. Louis College of Physicians and Surgeons in 1904, died at the St. Louis Baptist Hospital on March 30, of peritonitis following an operation for appendicitis.

Dr. Fenton L. Fulgham of Jackson, Mississippi, a graduate of the Kentucky School of Medicine, Louisville, in 1880, and a member of the Mississippi State and Hinds County Medical Societies, died at his home after a lingering illness, on March 29, aged 70 years.

Dr. Hiram Noble of Blair, Nebraska, a graduate of the Medical Faculty of Queen's University, Kingston, Ontario, in 1857, died at his home on March 22, aged 82 years.

Obituary.

CHARLES STEDMAN BULL, M.D.

NEW YORK.

Dr. C. S. Bull died on Monday of this week quite suddenly of disease of the heart. He was born in this city in 1845, was graduated in arts from Columbia University in 1864 and in medicine from the College of Physicians and Surgeons in 1868. After serving a term on the medical house staff at Bellevue Hospital he studied ophthalmology for a number of years in Europe. He was surgeon of the New York Eye and Ear Infirmary, visiting surgeon at the Charity Hospital, professor of ophthalmology at Cornell Medical College, and consulting ophthalmic surgeon at St. Luke's, the Presbyterian, and St. Mary's hospitals. From 1903 to 1907 he was president of the American Ophthalmological Society. He was a member of the New York County and State Medical Societies, the New York Academy of Medicine, the Practitioners' Society of New York, and the American Medical Association. Dr. Bull was one of the foremost ophthalmologists of the country, a careful and conservative practitioner, an acute observer, and a frequent contributor to the literature of his specialty.

Correspondence.

OUR LONDON LETTER.

(From our Regular Correspondent.)

HOSPITAL FINANCES, RE MEDICAL SCHOOLS—SUNDAY ENTERTAINMENTS AND THE SUNDAY FUND—SALVARSAN—OBITUARY.

London, March 31, 1911.

Two questions of hospital finance—both somewhat contentious—have occupied public attention this week. At the annual meeting of King Edward's Hospital Fund, on Tuesday, after the report which showed as prosperous a state as ever, the subject of payment by hospitals to school laboratories came forward. A committee which has been investigating this matter in reference to St. George's Hospital has found that such payments have been excessive, and inasmuch as they have worked out at about two and one-half times as much as the average of similar hospitals with schools, in London and in the Provinces, the conclusion cannot be contested. It is, however, complicated by considerations as to apportionment of rent, salaries, fees for analyses, and clinical and pathological research, so that the apportionment of expenditure between hospital and school may well give rise to differences of opinion. St. George's occupies one of the very finest sites in London, and the fair rental of such a position would be very high, and the other questions are as difficult to settle. Thus the amount spent on laboratories is very large. At a meeting this week at St. Mary's Hospital it was stated that the laboratory cost £600 a year. The committee made no effort to balance the various items, but decided on their general comparison that St. George's School should refund to the hospital the excess it had received for 1909.

The second question is much more controversial and may give rise to financial loss. It was raised at the Sunday Fund, which, as you know, depends on collections in churches and chapels. Some hospitals have participated in the profits of cinematograph shows held on Sundays. Consequently, some churches have ear-marked their collections for those

hospitals which refuse to share in such profits. It answers the purpose of the owners of these shows to open on Sundays and give the takings, less expenses, away. The County Council had sanctioned this and many charities, some very obscure, had agreed to such bargains. The counsel of the fund, while not expressing any opinion on the expediency of Sunday entertainments, proposed that in the event of the fund suffering diminution fairly attributable to this cause, the distribution committee should take that into consideration in making their awards. The Sunday Fund, differing from all other funds in that it was entirely dependent on Sunday collections in places of worship, the committee felt that circumstances must be considered. The opposite view was vigorously put forward, but after full discussion the proposal of the committee was carried with only seven dissentients.

Salvarsan, or 606, has a way of intruding into every medical conversation. Since I summarized the prevailing opinions here (Medical Record, Jan. 14 and 21) an animated discussion has been carried on at all sorts of casual meetings, and some more serious statements in point of opposing views. It is not possible to say that anything in the nature of a general conclusion has been arrived at. On the one hand, there is the same enthusiasm; on the other, an equal degree of doubt. Certainly, in the face of the numerous contraindications laid down, and of the admitted dangers, there is need for the strictest caution—especially when the drug is administered by transfusion into the veins, and this method seems to be growing in favor with those who have extensive experience.

Mr. C. F. Marshall is impressed with the risks of the remedy and the danger attending its use in a routine way. In his brief article in the *Medical Press,* as I reported to you in December, he showed himself an opponent, and in an expanded contribution to the *Lancet* he maintains his position. His conclusions may be stated thus: (1) No drug can replace mercury. (2) Salvarsan causes rapid healing of certain lesions, but this is temporary, and relapses have occurred. (3) There is no proof of an abortive effect. (4) It may be of use in those rare cases in which mercury fails, or cannot be tolerated; some resist both drugs. (5) The administration is not without risk.

At the London Hospital, as stated in my former letter, investigation has been carried out under strict precautions. The cases were under the care of Dr. Sequeira, and the laboratory experiments conducted under Dr. Bullock's authority by Drs. McIntosh and Fildes. The two last named have since stated their views in an article (*Lancet,* March 18), the tone of which might well have been less acrimonious. They begin by complaining of an undertone of criticism, and the suggestion that the drug has been "prematurely boomed," and proceed to attack Mr. Marshall for his "disparaging paragraph" in a journal and his longer article "in the *Lancet* itself." They go on to speak of expressions of disapproval as directly reflecting "upon the veracity, or scientific accuracy," of those who have previously described the effects of 606—a statement which appears unwarranted, and was perhaps evoked by the further remark that it included themselves. To lay down a dogma which must not be contradicted would put an end to progress in therapeutics, and even to all medical advance.

Drs. McIntosh and Fildes claim eight months' experience, and believe the results at the hospital of greater value than those, "if any, obtained by Mr. Marshall." This may very well be, but I would suggest to these two gentlemen that they are not really infallible, and that the "totally unfounded chorus of disapproval" which irritates them may possibly have some foundation in observation as careful as their own.

As you cannot give space to all their arguments against Mr. Marshall's views I will state the conclusions they feel justified in laying down:

1. On the average, if not invariably, 606 is far superior to mercury in syphilis.

2. In the earlier stages, and probably the later, at proper times, it will prevent the onset of symptoms with less inconvenience upon general health.

3. It will probably be used by the unskilled as subcutaneous or intramuscular injections for symptomatic treatment without danger.

4. The skilled will use intravenous injections in the hope, not without foundation, of realizing a therapia sterilans magna.

Mr. Marshall has, of course, replied to Drs. McIntosh and Fildes. In doing so he maintains in moderate terms the views he had put forward, and remarks that they are shared to a greater or less extent by a considerable number of experts. In fact, on the points at issue, he quotes Hutchinson, Buschke, Levy-Bing, Fischer, Finger, Stern, and others. But you cannot afford space for a fortification of opinions, in front of the additional literature that is accumulating on the subject.

Side by side with the article of Drs. McIntosh and Fildes summarized above is another in vivid contrast with its tone. This is by Major Gibbard and Captain Harrison, two officers of the R. A. M. C. at work in the Military Hospital, Rochester Row. They have also had assistance, cordially acknowledged, from Major Beveridge, who undertook a large number of chemical analyses for this investigation. The inquiry so far has been carried out on 150 cases, and of these almost all will continue under the observation of the authors for some time longer. The method of administration, the dosage, the immediate after effects of the remedy, and its influence on the clinical signs, as well as on the parasites, were all subjected to careful examination. So, too, was the effect on the Wassermann reaction. The question of relapses was also considered. In the early cases the subcutaneous and intramuscular methods of administration were tried, but they were discarded for transfusion into the veins, the important point as to this being great dilution of the drug since a concentrated solution so given would be highly dangerous. A full account of the technique and a description of a convenient apparatus is added. To test the drug where mercury failed cases were sent to the hospital, viz., ten in which mercury properly given had had no effect; twenty-two where it did not prevent relapse, and one in which it could not be tolerated. In all but one of these salvarsan was followed by complete disappearance of active signs.

The authors only offer their experience as a contribution to the evidence for and against 606 not as a judgment as to the position it will eventually occupy. Indeed, such judgment, they think, would be entirely premature, but their results seem to them to justify these conclusions: 1. The drug has a very marked and rapid effect on the clinical manifestations. 2. This effect is due to its action on the parasites and is not simply a cloaking of symptoms, as shown by the disappearance of treponemata from

local lesions and the effect on the Wassermann reaction. 3. It is impossible to say at present if this consists in destruction of the whole or only part of the parasites or simply in suppression of their activity. 4. The risk in using it being so slight, no judgment against it will be justifiable till every method of administering it has been worked out.

Dr. Thomas Reid, who has died in his eighty-second year, was surgeon to the Glasgow Eye Infirmary and Waltonian lecturer on ophthalmology in the university, appointments which he only resigned last year after holding them some forty years. He was M.D. and Hon. LL.D. of the university and had received an order of the Crown of Italy.

Dr. William Paley, J.P., died on the 13th inst. in his ninety-fifth year. He was physician to the Peterborough Infirmary for thirty-six years and subsequently an "extraordinary physician." He was a London Hospital alumnus, qualified at College and Hall, 1837-9, and in 1842 took the M.D. of the then juvenile University of London. He was a grandson of the theologian who wrote the "Evidences of Christianity." He retired in 1894.

Dr. Thomas Dobson, another nonogenerian, the oldest practitioner in Leeds, died on the 20th inst. at ninety-three.

Dr. L. S. McManus, who worked in Battuse for twenty-five years, died on the 26th inst. at fifty-four. That he was much respected by his brethren is seen in that they elected him to the General Medical Council in 1907.

The Indian medical service has lost a distinguished officer in Lieut. Col. J. T. W. Leslie, M. B., D. P. H., who has been sanitary commissioner with the government of India since 1904 and who has died at the age of forty-nine. He was in the Burmese expedition in 1885-6 and received the medal and clasp. In 1889 he was appointed inspector general of prisons, Burma, and in 1890 civil surgeon at Rangoon. Afterward he was made a chemical examiner and a professor in the Calcutta Medical College and somewhat later secretary to the director general I.M.S. In 1909 he was made C.I.E.

Among deaths in the R. A. M. C. are: Lieut. Col. Simpson Powell, who joined the army in 1885 as M.R.C.S. and took M.D. Denham in 1896. He was serving at Burma at the time of his death.

Lieut. Col. James Hector, who has died at sixty-nine, had retired in 1887 after serving from 1864. In the Zulu war of 1879 he was mentioned in dispatches and awarded the medal with clasp.

Major A. F. Tyrrell, who served throughout the South African war, was only forty-five and has died after an operation in the military hospital, Millbank. He held the Queen's Medal with four clasps, the King's with two clasps, and the medal for operations on the northwest Indian frontier 1897-8.

BERLIN LETTER.

(From our Regular Correspondent.)

ANTIVACCINATIONISTS.—SCHOOL MEDICAL INSPECTION.—TUBERCULOSIS CLINICS.—STATISTICS OF THE ANTITUBERCULOSIS CAMPAIGN.

BERLIN, March 15, 1911.

THE revision of the medical and sociological statutes with which our legislators are at present busied brings the antivaccinationists again upon the scene. The newest petition of the latter no longer demands the repeal of vaccination laws, but asks the removal of the compulsion clause. They would have something like the "conscience-clause" of England, under which when an infant is four months old parents may secure exemption of their child from vaccination, alleging conscientious scruples. It has been shown that since the introduction of this law in England in 1893 the mortality from smallpox in that country has greatly increased. In Germany, with the proximity of Russia, Austria, and France, the danger of infection would be much greater than in England with its insular isolation. For this reason the Berlin Medical Society has sounded a warning. The following resolution introduced by A. Baginsky was passed: "With reference to the recent discussions in the Reichstag the Berlin Medical Society deems it imperative that the German vaccination law of April 8, 1874, should be retained, and that the introduction of the English conscience clause would expose the German people to the greatest danger." This resolution was passed unanimously without debate, for this subject is as undebatable as that of the need of antisepsis in surgery.

The report of the officers of the association for school physicians for the year 1909-10 has just been published. It contains facts regarding the beneficent work of this young but most important institution. The number of school physicians is now fifty; the number of public school children is 223,000. There are, therefore, to every school doctor 4,475 children, of whom 684 are beginners. On account of physical or mental incapacity 3,024 of the children or 8.76 per cent. are kept back, a slight reduction from the percentage of last year. During the past year 20 per cent. or 45,000 of the public school children were examined. For the first time the work of a dental clinic established in one of the schools is described. In ten months 8,400 children were treated at this clinic, gratuitously in the case of those unable to pay, while those who were able to pay were charged at the rate of 50 pfennigs (12½ cents) for each treatment or filling. One hundred and sixty-two classes have been established for defective children. This provision for backward pupils is an advantage to the remaining children inasmuch as the effort of the teachers is no longer concentrated on the defective pupils. One per cent. of all the public school children are enrolled in these special classes. Formerly these children were given a trial of two years in the regular classes. Now they are kept under observation in intermediate classes before they are sent to the special schools for defectives.

The report on the tuberculosis clinics of Berlin for 1910 presents many important results. In the six clinics the patients are instructed and particularly the danger of infecting their neighbors is emphasized. A total of 37,000 persons including 20,000 children were thus looked after. These figures represent an increase of 100 per cent. over those of the previous year. Among the 37,000 patients there were 1,100 severely ill with open tuberculosis. For the latter the services of the visiting nurses were most important: the latter helped to improve the hygiene of the home and to instruct the patients and their relatives. By this means of showing the family how to prevent the spread of the infection it can be hoped eventually to stamp out the disease? The hospital treatment can never excel this system of visiting nursing. During the past few years the hospitals have been requested to report to the visiting nurses' bureau all cases of open tuberculosis that are admitted in order that the nurses might visit the homes of the patients and instruct the relatives

of the latter as to disinfection of the premises and as to other hygienic measures. In addition to the cases in which the relatives provided for the disinfection themselves there were disinfected by the municipal sanitary authorities 351 dwellings of tuberculous patients and in 1,016 additional instances in which death occurred the nurses' bureau was notified. Donations of cash, lunches, milk, the provision of nurses, were all part of the program for the relief of the tuberculous. About 2,300 individuals were admitted to sanatoria, 2,000 were kept under observation by private practitioners and in polyclinics, and 367 were admitted to hospitals. There were seventeen visiting nurses who each made seven or eight visits every day. Since physicians and nurses are overburdened with this work increased funds and facilities for relief are imperative.

THE EIGHTH ANNUAL MEETING OF THE PHILIPPINE ISLANDS ASSOCIATION.

(From Our Regular Correspondent.)

(*Concluded from page* 690.)

MANILA, P. I., February 25, 1911.

THE third session of the Eighth Annual Meeting of the Philippine Islands Medical Association was held on the afternoon of February 23, 1911.

Owing to the fact that Dr. Richard P. Strong and Dr. Oscar Teague had proceeded upon very short notice to Peking, China, in order to take part in the international fight which is being made against the plague, three of the papers upon the afternoon's program suffered accordingly.

A paper entitled "The Use of '606' by the Intravenous Method in the Treatment of Syphilis" was read by William S. Shields, M.D., First Lieutenant, Medical Corps, U. S. A. The author confirmed the experience of other workers that the most satisfactory manner of employing "606" was by the intravenous method, and his results agreed with those which have already been so numerously recorded in medical literature.

A paper entitled "Treatment of Syphilis with Ehrlich's Salvarsan" was read by Dr. Donald Gregg. In this paper the author gave a series of thirty-five cases that had been treated both by the intramuscular and intravenous methods. A case of locomotor ataxia was reported in which rather alarming symptoms occurred. The heart's action was greatly depressed, the pulse at the wrist became almost imperceptible, and the patient lost consciousness for several hours. The results in cases of yaws were uniformly satisfactory, the lesions disappearing in every instance within a period of two weeks.

A paper entitled "Physiological Influence of Tropical Heat" was read by Dr. Hans Aron, Professor of Physiology, College of Physicians and Surgeons, University of the Philippines. This paper attracted probably more general interest than any that was read at the session, and gave an account of some experiments which the author had undertaken with monkeys and human beings for the purpose of showing the influence of heat upon the animal organism. The author showed that when a monkey was placed in the direct sunlight it frequently died within a period of fifteen minutes, while another monkey under similar conditions, except that it was put in the shade of an umbrella, was apparently unaffected. Another series of monkeys were placed in cages, with their heads exposed to the sun and their bodies shaded, and it was found that under these conditions the monkeys would survive several days, whereas monkeys entirely in the shade were unaffected. Another monkey was placed in the sun, but under the influence of an electric fan, and it was found that under this condition it survived.

An examination was then made of a number of Filipinos and Europeans, which showed that Filipinos sweat more evenly and uniformly than Europeans or Americans; in other words, the Filipinos' entire bodies were covered by a thin film of moisture which under the constant evaporation taking place kept their bodies in a cool condition. In the Europeans it was found that when they were placed in the sunlight they sweat profusely, large quantities of perspiration running to the ground, sweating being practically sectional; that is to say, certain portions of the body exuded large quantities of sweat, while other parts remained comparatively dry. From this it will be apparent that the cooling effect on the body is very much less than that in the Filipino. An examination of the skin showed that the Filipinos were provided with a very much greater and more evenly distributed number of sweat glands than the American or European. Again it was found that when the Filipino was placed in the sun he frequently had an elevation of one degree centigrade, but upon being placed in the shade he immediately resumed his normal temperature; whereas when the American or European was placed in the sun he had a similar elevation of temperature, which persisted for a number of hours after he was placed in the shade under more favorable conditions.

The fourth and last session began on the morning of February 24, 1911.

The first paper read was entitled "A Preliminary Account of Some Experiments Undertaken to Test the Efficacy of the Ipecac Treatment of Dysentery," by Edward B. Vedder, M.D., Captain Medical Corps, U. S. A., Member of the U. S. Army Board for the Study of Tropical Diseases. In this paper the author stated that he had made a large series of experiments upon cultures of amebæ which invariably showed that when ipecac was added, even in the dilution of 1 to 50,000, their growth was effectually inhibited. He mentioned many cases that had been successfully treated with the ipecac method and thought that his laboratory experiments furnished a satisfactory reason for the efficiency of this treatment in amebic dysentery.

In the next paper, entitled "A Comparative Study of the Amebæ found Microscopically and Culturally in the Human Intestine," by Dr. Walker of the Bureau of Science, the author stated that he was engaged upon a study to ascertain in a definite way whether pathogenic amebæ could be distinguished from nonpathogenic amebæ. His work had already proceeded sufficiently far to warrant him in stating that there were distinct biological differences in the two classes of amebæ. In the ordinary water amebæ, which were regarded as harmless, he found that the granules in the nucleus were arranged around the periphery, whereas in the other class found in the human intestine the granules were arranged centrally. The author stated that at this time he was unable to make a complete report, but he felt certain that raw green vegetables or water in the tropics were incapable of causing the disease unless they were previously contaminated with the stools of a case of amebic dysentery.

The next paper, entitled "Immunity Reactions with Amebæ," was read by A. W. Sellard, Assistant, Biological Laboratory, Bureau of Science.

The next paper, entitled "A Study of Intestinal Parasites Found in Cavite Province," was read by Dr. E. R. Stitt, Surgeon, U. S. Navy. In this paper the author gave a series of over 900 stool examinations made of sailors and residents of Cavite province. He found that but 2 per cent. were infected with hookworms, which is by far the lowest percentage yet reported in the Philippines. He found, however, a 35 per cent. infection with amebæ and explained that this larger percentage might be due to the fact that he had discovered that the percentage of amebæ found was very much greater when the examinations are made within a period of two hours from the time that the stool is passed. The same stool examined five or six hours after it was passed did not show amebæ. He found an ascaris lumbricoides infection of over 60 per cent. and also reported that the amebæ infections among the sailors had been kept under observation for a period of six months and none of them showed any symptoms of amebic dysentery.

The next paper, entitled "Hookworm Infection in the Philippines," was read by Liborio Gomez, Assistant, Biological Laboratory, Bureau of Science. In this paper the author gave a series of eleven cases of hookworm infection that had come under his observation. In the discussion which followed it developed that the influence of other parasites had not been sufficiently eliminated, and it was difficult to state to what extent the symptoms in his cases were due to hookworms and to what extent they were due to other intestinal parasites.

The next paper, entitled "Ascaris Lumbricoides Infestation of the Liver Causing Death, Report of Two Cases," was read by Dr. V. L. Andrews. This paper was of great interest in that it is among the first instances in which the seriousness of *Ascaris lumbricoides* infection was conclusively demonstrated. The author stated that in the text books on medicine of Osler, Wilson, Manson, Twentieth Century, and many other standard authors, there was no mention of the pathological importance of this parasite. The author exhibited a liver which was thoroughly riddled with adult round worms, which varied in length from a few centimeters to twenty centimeters. These had caused general abscess formation throughout the liver. He exhibited another liver from a child five years of age in which the diagnosis had been abscess of the brain. In this case the liver was filled with round worms, many of which penetrated the liver tissue to the periphery of the organ, which had caused abscess formation resulting in death.

The next paper, entitled "Studies in Balantidium Infection," was read by Fred. S. Bowman, Assistant, Biological Laboratory, Bureau of Science. The author gave the history of two cases which had resulted in death and stated that the prognosis in this disease was bad, even when treatment was begun early, and absolutely hopeless in the latter stages of the disease. He showed a series of lantern slides in which the organisms were shown by sections to be in the deeper layers of the intestinal mucosa.

The last paper of the session, entitled "The Fleas and Rats Concerned in the Transmission of Plague," was read by Dr. Carroll Fox, Passed Assistant Surgeon, U. S. Public Health and Marine-Hospital Service, Assistant Director of Health. The author gave a brief description of the anatomy of the *Pilex cheopis* and the distinguishing points between these and other fleas commonly found upon rodents.

At the business session which immediately followed, the following officers were elected for the ensuing year: *President*, R. E. L. Newberne, M.D.; *Vice-Presidents*, Major Henry A. Shaw, Medical Corps, U. S. A., Dr. Fernando Calderon; *Secretary-Treasurer*, Dr. Vernon L. Andrews; *Councillor for five years*, Dr. Richard P. Strong; *Councillor for four years*, Dr. Benito Valdez.

Progress of Medical Science.

Boston Medical and Surgical Journal.

April 6, 1911.

Some Observations on the Disorders of the Stomach and Duodenum with Especial Reference to Ulcers. W. J. Mayo.
Duodenal Ulcer. F. W. White.
Present Treatment of Gastric and Duodenal Ulcer. A Review of the Recent Literature on the Subject. C. Frothingham.
Indications from a Medical Standpoint for Operative Procedures in the Presence of Chronic Gastric Symptoms. M. V. Tyrode.
Sudden Death Following a Prophylactic Dose of Diphtheria Antitoxin. Autopsy Reveals Status Lymphaticus. S. F. McKeen.

Ulcer of the Stomach and Duodenum.—W. J. Mayo states that acute ulcers are usually toxic and the patient either dies or recovers within two or three weeks. Neither experimentally nor clinically have these acute ulcers been found to be responsible for the chronic calloused ulcers of the stomach and duodenum. Actual inspection through exploratory incision shows conclusively that both duodenal and gastric ulcers are more often found in the male sex, that chronic duodenal ulcer is more common than gastric, and, in the large majority of cases, only a single ulcer is present. Gastric and duodenal ulcers may exist for years. The disease usually begins in the young adult who develops a history of stomach trouble marked by bitter, sour, acid belching and regurgitation coming on from one to three hours after meals and relieved by taking food. With or without treatment the symptoms will abate and, in the early history, will disappear for months or years at a time, leading to the delusion that the ulcer is cured. These "spells" recur at closer and closer intervals until, in the later stages, obstruction supervenes and, as the acids then diminish and blood is sometimes present, the patient is thought to have cancer.

Duodenal Ulcer.—F. W. White believes that duodenal ulcer is a "coming disease," something like appendicitis twenty to thirty years ago. The symptoms are regular, definite, not easily mistaken, and have few exceptions. They are marked by their long duration. The majority have lasted three, five, ten, or fifteen years. The symptoms are intermittent, often completely so, the attacks lasting a few weeks or months. The large majority of the patients are males in middle life. The most striking and constant symptom is regular recurrent epigastric pain eased by food and alkalies and later returning two to four hours after a meal, the so-called "hunger pain"; after a light meal it appears earlier. The early diagnosis of duodenal ulcer from simple hyperacidity seems to be a matter largely of severity of symptoms and recurrences and of the presence of occult or gross bleeding.

Treatment of Gastric and Duodenal Ulcer.—C. Frothingham outlines the treatment as follows: Acute uncomplicated ulcer—medical means; acute ulcer complicated with hemorrhage—medical means; acute ulcer complicated with hemorrhage, chronic ulcer complicated with uncomplicated ulcer—medical means soon to be followed by surgical if former are unsuccessful; chronic ulcer complicated with hemorrhage, chronic ulcer complicated with perforation, chronic ulcer complicated with real stenosis—surgical treatment.

Indications for Operation in Presence of Chronic Gastric Symptoms.—M. V. Tyrode concludes that cases in which he orders immediate operation and refuses medi-

cal treatment after the test diet are those suffering considerable pain and having shown no marked improvement within two weeks. Cases for which he recommends operation and treats only conditionally, explaining risks, are those improved but not wholly cured by test treatment of few weeks' duration, showing some pain and local sensitiveness at either upper quadrant or at McBurney's point. Cases where, to his mind, question of operation does not enter are those in which the first attack is rapidly and completely cured in two weeks' test treatment: or in others where constitutional diseases form a contraindication to surgical procedures.

Death Following Prophylactic Dose of Diphtheria Antitoxin.—S. F. McKeen reports a case of death in a girl of seventeen following the injection of 500 units of diphtheria antitoxin. There had been a history of asthma associated with albuminuria and of a chronic watery rhinitis. Autopsy revealed the status lymphaticus.

New York Medical Journal.

April 8, 1911.

Address to the Training School for Nurses of the New York Hospital. G. L. Peabody.
A Contribution to the Study of Fats and Lipoids in Animal Tissue. —III. J. Wright.
A Series of Studies of Nervous Affections in Relation to the Adjustments of the Eyes. G. T. Stevens.

Ozone. M. W. Franklin.
Cacodylate of Sodium in the Treatment of Syphilis. O. L. Suggett.
Sodium Cacodylate in Syphilis. H. A. Schirrmann.
Rabies. J. A. McLaughlin.
Morphinism and Morphinomania. F. N. Bell.

Address to Nurses.—G. L. Peabody states that the training school idea which is so often erroneously attributed to Florence Nightingale, took its origin in Germany and was started not by a woman, but by Theodor Fliedner, who was a Protestant clergyman and philanthropist.

Fats and Lipoids in Animal Tissue.—J. Wright states that the tissue components of the tonsils exhibiting to the microscopist the presence of lecithin are shrouded in mist.

Adjustments of the Eyes.—G. T. Stevens states that the habitual pose of the head in relation to the general pose of the body furnishes a tentative explanation of the intimate relations between the anomalies of adjustments of the eyes and the functional affections, such as the mimeses and neurasthenia.

Psychoanalysis.—A. Gordon in summing up the discussion on the nature of psychoneurosis and hysteria states that their chief characteristics consist of a continuous conflict between the ideas of the conscious ego and the unconscious mental processes separated from the ego, which the latter could not assimilate, but instead submerged them, tried to forget them, and succeeded only in repressing them. Not being destroyed, they remain in an unconscious state and act as an irritant to the conscious ego. At one time or another they will produce various morbid manifestations in the psychic or motor sphere and organize symptom groups commonly observed in psychoneuroses and hysteria.

Ozone.—M. W. Franklin notes that ozone in consequence of its great oxidizing activity is a powerful and rapid disinfectant.

Cacodylate of Sodium in Syphilis.—O. L. Suggett states on the basis of an experience with ten cases that this remedy is of but little, if any, benefit in the primary or early secondary stages of syphilis, seeming to have an irritative rather than a resolutive effect.

Cacodylate of Sodium in Syphilis.—H. A. Schirrmann reports three cases treated with this drug with strikingly beneficial results.

Rabies.—J. A. McLaughlin states that the subject of rabies has reentered an old field, that of the veterinary practitioner. The laboratory has not "made good"; the Negri bodies are still on trial. Rabies is a common disease, its symptoms may be a pneumonia, an inflammation of the bowels, distemper, a cold, or one of many other manifestations.

Morphinism and Morphinomania.—F. M. Bell defines morphinism as the habit of taking morphine in small doses for the relief of pain and without any appreciable increase in dosage, except as necessity demands. Morphinomania, on the other hand, is a condition in which morphine is taken for pleasure or as a stimulant and in ever-increasing doses.

Trichiniasis in Italians Following the Eating of Raw Ham. M. Seymour.
Treatment of the Paralysis Following Acute Poliomyelitis. J. M. Berry.
Two Cases of Cesarean Section with Unusual Complications. C. Foulkrod.

Medical Education.—A. H. Ferguson points out the overcrowding of the profession in this country as compared with European states and sees in it not the survival of the fittest, but the survival of the unfit. The remedy pointed out is free medical education, which he thinks would insure a proficient medical profession, protect the public health, and educate the public on medical matters.

Antityphoid Vaccination.—J. P. Fletcher describes the method of administering prophylactic antityphoid vaccinations in the United States Army. In brief, the method used consists in making three subcutaneous injections at ten-day intervals of a killed culture of *B. typhosus* prepared in the laboratory of the Army Medical School at Washington, D. C., sent out in sealed ampoules and containing 1,000,000,000 dead bacilli per cubic centimeter. The injections are made in the posterolateral aspect of the arm. The first dose is 0.5 c.c. and the second and third doses 1 c.c. each.

Phosphorus Poisoning.—R. H. Ivy states that a local infection of the jawbone by the phosphorus through diseased teeth is the essential factor in necrosis. In view of the results of observations on 177 persons for periods ranging from six months to two and a half years, it is justifiable to conclude that the measures in operation at the present time are effectual in the prevention of necrosis in persons employed in the manufacture of matches from white phosphorus, and that the substitution of other less satisfactory materials is unnecessary.

Tying the Square Knot.—H. E. Castle and H. A. L. Ryfkogel state that the time consumed in tying sutures and ligatures during many surgical operations is too great in proportion to the time taken to do the rest of the work. The circumstances under which ligatures must be tied often render the work most difficult and unsafe when done in many of the ordinary ways. The authors describe an efficient and time-saving method of tying the square knot.

Innocent Gallstones a Myth.—W. J. Mayo states that every patient with chronic gastric distress should be questioned intelligently to obtain any former history of gallstone colic, since this may have escaped the patient's attention. Gallstone disease sometimes causes serious circulatory disturbances, such as endocarditis, which, though rare, is of a specific type and in its origin is coincident

with the gallstone attack. Subsequent attacks aggravate the heart action. While stones are the most common cause of cholecystitis, this is not always the case, but the patient still requires operative relief. It is usually in those cases accompanied by habitual tenderness in the region of the gall-bladder that colic is not so prominent. Complications were found in more than two-thirds of the patients operated on at Rochester. Stones were found in the common duct in 531 cases with an operative mortality of 6.5 per cent., while serious complications involving the liver, duodenum, transverse colon, etc., were the rule. Carcinoma was found in eighty-five cases (2.25 per cent.). In a number of the cases slightly advanced cases of carcinoma were accidentally encountered before they had advanced sufficiently for diagnosis, in removing thick-walled functionless gall-bladders, and five of these patients are still alive and well from two to six years after operation. Gallstones are foreign bodies and the author believes that one should not delay operation until complications ensue. Simple operation for uncomplicated gallstones has a mortality of less than 0.5 per cent., and this is due more to the condition of the patient than to the operation. While temporary palliation may be obtained with no non-operative measures, the patient can only be thoroughly cured through surgery.

Uncinariasis.—C. F. Strosnider points out the prevalence of uncinariasis in the southern part of our country. He classifies the disorder into four types: mild, medium, severe, and excessively severe cases. The first named have no recognizable symptoms as yet other than slight digestive disturbance and some possible discomfort. The medium cases are characterized by dirty yellowish complexion in whites, and slight pastiness in mulattoes, reduced perspiration, often excessive appetite, epigastric pain or uneasiness, slight dyspnea on exertion, palpitation, dizziness, headache, mental dullness, flabby muscles, and indisposition to work; joint symptoms, especially in the sternum, and slight rise of temperature are also often present. In the severe cases the same symptoms are present, only more marked, and there is decided mental depression. In about ten days after ground itch appears the patient usually develops a sore throat, a slight bronchitis, and a temperature ranging from 99° to 102° F. Swelling of the face may occur and the hemoglobin is apt to be between 45 and 70 per cent. In the very severe cases the symptoms are still more aggravated and death may occur at any time. Acute hookworm disease may occur primarily or may supervene on a chronic infection. One difference between acute and chronic cases is the waxy white skin with severe anemia in the former, whereas in chronic cases, with the same anemia, there is a yellower tinge. Insomnia and night terrors are common in hookworm disease and chronic somnolence is not rare. After administration of thymol the temperature frequently rises to 102° or 104° F., usually subsiding in twelve hours, which the author explains as probably due to the irritation of the worms causing them to excrete their toxin rapidly and at once.

Sanitation of Health Resorts.—H. B. Wood states that in maintaining state sanitary control there should be classed as health resorts all towns usually advertised or considered as resorts, hotels used by summer or winter visitors, pleasure or recreation resorts, parks and camps, the so-called watering places, medicinal springs, and localities or institutions advertised as sanatoria. The adoption of legislation putting all hotels under sanitary inspection and fixing a standard of efficiency is desirable. Mineral spring resorts should be placed under licensure, their value being determined by competent authorities, and frequent sanitary inspections made. The exaggeration of the curative qualities should be placed in the same category as misbranded nostrums.

Trichiniasis.—M. Seymour states that trichiniasis is more common than is generally supposed, being erroneously diagnosed as typhoid fever, muscular rheumatism, influenza, laryngitis, neuritis, nephritis, and many other diseases. The diagnosis is not difficult, if in every case of generalized muscular pain a differential count of the leucocytes is made, and, if possible, a bit of muscle excised for examination. More rigid examination should be made at the ports of entry of foreign meat products, especially those of pork. The eating of all raw animal foods—sausages, ham, smoked beef, and the like—should be condemned. Much can be accomplished by the physician who comes in contact with the Italians in pointing out the dangers of eating underdone or raw pork foods.

Poliomyelitis.—J. M. Berry discusses the methods of treatment of the paralysis following acute poliomyelitis. The electric treatment by the galvanic current is of much more value than that by the faradic, and is of value chiefly in the preservation of the nutrition of the paralyzed muscles until the return of voluntary control. It is useful, therefore, only in the early stages and not after the paralysis has become stationary. The brace treatment is useful in preventing deformity and preventing overstretching of muscles, but mild cases may do better without it and the weight and pressure of the apparatus are damaging in severe ones.

Cesarean Section.—C. Foulkrod reports two cases that illustrate well the success attained in some complicated cases by the use of abdominal delivery.

Some Experiments on the Inhibition of Tumor Growth in Rats and Mice, with a Suggestion for an Empirical Treatment in Man. H. S. Grünbaum and A. S. Grünbaum.

Ankylostoma Infection.—A. E. Boycott discusses the prophylaxis and treatment of this condition. He finds that thymol and β-naphthol are about equally efficacious in expelling the worms, one dosing (*i.e.* two half-drachm doses) of either killing on the average about 75 per cent. Thymol has the disadvantage that it costs about five times as much as β-naphthol, but after a lengthy trial the latter drug was eventually discarded in favor of thymol owing to the discovery that β-naphthol may set up a fatal acute nephritis in persons whose kidneys are already somewhat diseased.

Melancholia.—G. M. Robertson states that Kraepelin conceived the idea that mania and melancholia are different, but equivalent, manifestations of the same underlying disease process, just as the various phenomena of epilepsy are similarly related. The author concludes that the primary and fundamental symptom in melancholia is a feeling of depression or mental pain. The other mental symptoms appear to be secondary to it, and in all probability many of the physical phenomena are also secondary. It is believed that centripetal nervous impressions come from all the organs and tissues of the body, and these arise from the metabolic processes which occur in them during their functional and trophic activities. Although we are unconscious of these individually, yet these impressions in the mass are the basis of our feelings of well-being or of malaise as the case may be, and they form the background of our consciousness—the cœnesthesis. In melancholia it would appear that accompanying a sluggish and defective metabolism, with diminution in the pro-

duction of nervous energy, there is an organic feeling of ill-being, which is reflected in consciousness as a subjective feeling of misery or mental pain, without any exciting cause in the environment of a mental nature.

Diagnosis of Gallstones.—J. Sherren states that attacks of "colic" resembling those due to gallstones may be the result of movable kidney or of duodenal ulcer. It may be impossible to make a certain diagnosis without operation. In the majority of patients with gallstones "indigestion" is present for several years before the first attack of colic. This indigestion has certain features which often enable a diagnosis to be made, but is sometimes suggestive of gastric or duodenal ulcer. An attempt should be made to recognize the condition early, so that operation may be performed at the ideal time while the stones are still in the gall bladder.

A Case of Cor Triloculare Biatriatum.—J. I. Robertson states that the main anatomical peculiarities in this case of deformity of the heart are as follows: (1) dilated left auricle; (2) dilated sinus venosus; persistence of venous valves with marked hypertrophy of the right valve; (3) small right auricle; obliteration of tricuspid opening; presence of an interauricular foramen; (4) almost complete obliteration of right ventricle; (5) persistence of the bulbus arteriosus; presence of two interventricular foramina; (6) transposition of the large vessels, aorta in front arising from the bulbus arteriosus; pulmonary artery behind arising from the left ventricle; and (7) persistence of a patent ductus Botalli.

Thyroid Enlargement in School Children.—C. W. Hutt calls attention to the fact that slight general enlargement of the thyroid is fairly common in some school districts. The number of cases investigated does not warrant any very definite conclusions.

Fading of Microscopical Preparations.—A. C. Coles states that practically all substances of the nature of balsams, oleoresins, or cedar oil will sooner or later oxidize and become acid, and therefore are liable to cause fading of aniline stains. He has found that preparations may safely be mounted in liquid paraffine or parolein, which is absolutely neutral and will remain so.

Extensive Blistering in an Infant.—S. Bott reports a case of this condition in which the diagnosis was scurvy, modified by the tropical climate.

Inhibition of Tumor Growth.—H. S. Grünbaum and A. S. Grünbaum have found that in rats regression of inoculated growths may follow the injection of epitheliomatous horse serum and also of simple horse serum, and that this regression occurs in a greater proportion of treated than of untreated rats.

Note on the Therapeutics of Sugar. Sir James Sawyer.
The Cardigan Cancer Cures. G. M. Dawkin.

Acute Emergencies of Abdominal Disease.—B. G. A. Moynihan concludes that the catastrophes which occur within the abdomen are not, strictly speaking, "acute"; they are, on the contrary, usually the result of the abrupt transition from a quiescent to an acute phase in a disorder of long standing. An acute emergency can, therefore, be prevented by a timely recognition of the value and the significance of the early symptoms, so often ignored or misunderstood, of the chronic malady in which it is the final development. The occurrence of a sudden attack of intolerable agony in the abdomen, associated with tense rigidity of all the abdominal muscles, indicates that there is an acute lesion which needs immediate surgical attention. These two signs, and these alone, are an urgent warrant and compulsion to us to treat the case at once by operation. A differential diagnosis is generally possible if strict attention be paid to the details of the anamnesis, and if the firm abdominal wall be searched for a tender area of supreme resistance. Shock is not a symptom of perforation, for in the early hours after this disaster has occurred the pulse is very little altered in volume or in rate. In all cases of abdominal pain, especially in children, the use of aperients should be avoided.

Formation of Renal Calculi.—B. Moore states that the formation of renal calculi has for its basis a condition of diminished oxidation, in which there appear primarily calcium salts of incompletely oxidized bodies, such as calcium oxalate and calcium urate, associated with calcium phosphate. Further, such diminished oxidation, occurring locally or generally, is seen in many pathological conditions, such as calcium salt deposition in bone in old age, in tuberculous lesions, in gout, in arteriosclerosis, and generally in calcification processes in the body. The tendency toward such deposition increases with age, and is probably accompanied by an increased alkalinity of the body fluids.

Diagnosis of Smallpox.—A. F. Cameron approaches the subject of diagnosis from the point of view of the practitioner who may be called upon to examine, and perhaps forthwith to express his opinion on, a suspected case of smallpox.

Renography.—E. H. Fenwick describes his method of *x*-ray diagnosis of movable kidney. The diagnosis of movable kidney is not difficult when the kidney is palpable. But in the more important group, those kidneys which do not drop greatly but which rotate on an anteroposterior axis, and in doing so kink the fixed ureter and induce back pressure, it may not be possible to palpate the kidney. In this case radiography is of aid. It is easily done if an oxalate of lime stone chances to be in the pelvis, for its shadow rises and passes inward on forced inspiration. But if there is no oxalate of lime stone, if collargol is injected into the renal pelvis one will obtain a shadow. On the movement and the contour of that shadow in inspiratory effort, whether it opens out or becomes restricted in outline, whether it moves in and up or out and up, will be demonstrated the movements of the kidney. Pyelography will open up a hitherto closed book of problems in the causation of the pathology of surgical affections of the kidney, and its pages will surprise and charm the worker and render renal surgery more accurate, and therefore more beneficent, than has hitherto obtained.

Internal Anthrax.—W. Mitchell advocates the use in pulmonary anthrax, or woolsorter's disease, of injections of Sclavo's antianthrax serum. He believes that woolworkers acquire slight forms of anthrax which give them immunity.

The Infective Granule in Protozoal Infections.—A. Balfour has come to the conclusion that the endoglobular bodies in spirochetosis of Sudanese fowls represent a stage in the life history of the spirochete.

Therapeutics of Sugar.—Sir. J. Sawyer records that he has used cane sugar freely and frequently during the last ten years or so with success in a variety of morbid conditions. In wasting disorders, in various forms of anemia, in adynamic varieties of rheumatism, and especially in the neurasthenic manifestations of neurotic persons he has found the continued ingestion of cane sugar markedly beneficial, increasing weight and power, and appearing to act not merely as a nutrient but also as a tonic in the best senses of that word—namely, as a very valuable medicine,

the continued administration of which in debilitated and relaxed conditions of the body imparts strength and vigor without producing any sudden excitement, and as a corroborant gently stimulating the vital energies to an aroused action by a kind of mild stimulation, slowly produced and permanent in effect.

Cardigan Cancer Cures.—G. M. Dawkin states that in no case has he known an authentic and unquestionable malignant growth yielding to the Cardigan cure, and he thinks all the boomed successes are cases of warts, fibromata, and other non-malignant conditions.

Berliner klinische Wochenschrift.

March 27, 1911.

Renal Decapsulation and Allied Measures.—Zondek considers these operations in great detail. They have seemed to benefit and to save life, especially in eclampsia cases. But they are not proven yet to be wholly scientific, for there has been a great dearth of pathological and experimental work and there never have been any strict indications laid down for operating in individual cases. If merely relieving the tension of the renal capsule is in question this may be done by simple nephrotomy, scarification, or decapsulation. The precise indication cannot always be fixed. Even after nephrectomy we cannot always look back and say what course would have been better. Nephrotomy is used in diagnosis as well as for therapy, and a calculus or tuberculous focus may accidentally be brought to light. This operation is therefore a useful routine procedure, although evidently not of much service in a perfectly bilateral disease (medical as distinct from surgical kidney). Decapsulation for eclampsia, while seemingly successful in half the cases practised, has been subjected to a sort of deadly parallel which seems to show that the class of cases rescued by that operation have been saved to the same extent by the old competitive procedures. Let us take for example the so-called glaucomatous kidney, and we can understand how the prompt and thorough relief of tension produced by decapsulation might save life. But often the kidney is not tense, but pale and flabby. The operation was clearly not indicated, yet the patient has been apparently rescued. Zondek believes at the present that when anuria seems almost complete, eight or ten hours after delivery, we are justified in decapsulating for tensely swollen kidney, but should the latter be pale and flabby simple scarification or removing a strip of capsule should be sufficient. When severe acute parenchymatous nephritis is of a toxic origin the resemblance to eclampsia is so suggestive as to indicate one of the capsular operations. Two types may be mentioned at random, viz., sublimate poisoning and scarlatinal nephritis. To a certain extent this may hold good for any kind of acute nephritis in which anuria impends. In such cases scarification with or without the additional removal of a strip of capsule should suffice. Decapsulation might be employed as a later resort. We do not yet understand how these operations can overcome anuria. But Edebohl's contention was from the first that decapsulation held out some hope of recovery from chronic nephritis by leading to the formation of a collateral circulation. This is a much more serious question than the relief of anuria, as it concerns an affection which never recovers spontaneously. The direct way to settle its possibilities is to determine the results of ligation of renal arteries and thus learn of the limitations of collateral circulation. At present the results of animal experiment seem to show that such circulation is possible. The kidney should always be subjected to nephropexy after decapsulation.

Case of Fistula Between Gall Bladder and Appendix.—Tanaka of Nagasaki describes a case in an old woman in whom an anastomosis occurred between these two organs. The patient was badly diseased, having multiple tuberculous lesions; bilateral pyelonephritis (evidently from calculi); arteriosclerosis with resulting lesions (including an area of softening of the brain); cholecystitis, and so on. The number of lesions could be multiplied, but would only serve to confuse the reader. The main question was, "How could a fistulous communication be established between the appendix and gall bladder?" Simple tuberculous destructive processes could not alone explain it, and in any case the appendix was not tuberculous. The author then takes up the subject of anomalous position of the appendix. Many authors are quoted, but it does not appear that any regularity of findings occurs. The appendix may become adherent to a great variety of organs. It seemed evident that the appendix, in the author's case, was the first to be attacked and that there coexisted a cecum mobile with long mesentery. In such a case the appendix would have been first of all inflamed, while a periappendical abscess would have served to implicate the gall bladder. Conversely, with anomaly of arrangement a primary cholecystitis may have caused a pericholecystitis which could have set up a perforation-appendicitis. Every evidence shows that the process began within the gall bladder, but the rationale does not seem clear.

Münchener medizinische Wochenschrift.

March 28, 1911.

Syphilis in the Lower Animals.—Hoffmann sums up our results as to experimental syphilis as follows: If we inoculate the lower apes subcutaneously, we get at times insignificant evidences of secondary syphilis. But if we inoculate the same animals in the scrotum, we obtain after three months very characteristic generalized syphilis—papulous, pustulous, etc. Syphilis is found to be a local malady until the spirochetes enter the blood, but this occurs at so early a period that the malady may be termed constitutional from the start. It is an error to believe that rabbits, etc., are more susceptible to syphilis than the higher animals. The peculiar susceptibility of small laboratory animals to corneal and testicular inoculation is misleading in this direction. Nevertheless, corneal studies of inoculation in rabbits, etc., are full of interest. Double inoculation of the anterior chamber "takes" in nearly all cases. In about one-half the cases inoculation of one eye is followed after about two months by syphilis of the opposite eye. The corneal lesion, nominally a keratitis, is actually a syphiloma, but one which may resemble structurally a tuberculous neoplasm. However, it seems able to imitate almost any type of corneal disease. Thereby it differs wholly from the syphilitic keratitis of human beings, which is not only never a primary lesion, but also falls under a few definite types. The primary inoculated syphiloma of the cornea in animals remains a lesion *sui generis* and as such must be considered in pathology, with no reference to any other lesion whatever.

Serodiagnosis of Trichinosis.—As is well known, the echinococcus disease may be diagnosticated by a reaction analogous to the Wassermann procedure. The same fact has been demonstrated in connection with trichinosis, but the chemical application is more difficult. Antigens may be obtained in various ways, chiefly from the worm itself, but are very variable in action. Similarly antisera have often been prepared chiefly along the Wassermann lines. Thus antigens and antisera of all kinds have been combined into a formula, varied in many ways. Ströbel, the author, finds that in certain cases of trichinosis the Wassermann type of reaction is of use for diagnosis. Fixation of complement is necessary for its success. The reaction

is specific and shows no connection with the echinococcus reaction. The antigen formed in the one affection differs radically from that produced by the other. In this connection the Weichardt's epiphanin reaction may be mentioned. This is to be found in the *Münchener medizinische Wochenschrift,* 1910, No. 38. Both the author's and Weichardt's tests should be tried in all suspected cases of trichinosis.

On the Glyzyl-Tryptophan Test for Cancer of the Stomach.—Neubauer and Fischer recall their discovery that the gastric juice of a cancer patient often contains an enzyme which, unlike pepsin, is able to split up dipeptids such as glyzyl-tryptophan. They have followed up this kind of research and their conclusions to date are as follows: Normal gastric juice does not split up glyzyl-tryptophan, but the stomach contents of surely known gastric patients give the said reactions (84 per cent. in autopsies and 75 per cent. in clinical cases). Miscellaneous gastric diseases give a positive result in not over 12 per cent. of cases. Naturally, then, this test is favorable only in cases which present a particular history.

Lipogenous Diabetes.—Kisch states that obesity is the determining cause in all juvenile diabetes. That is to say, juvenile and inherited obesity are present as factors in a large class of such cases. In those who seem to take on fat late in life, but still from an inborn tendency, diabetes often develops, but in no greater proportion than in those who become fat from sedentary life and overfeeding. It is well known that those predisposed have a tendency to boils and carbuncles as well. Lipogenous diabetes is to be found also in those who become obese after some acute infectious disease, chronic alcoholism, syphilis, etc. The course of lipogenous diabetes tends always to be severe and rapid; and the only treatment in such cases is a strictly anti-obese regimen—in fact, that pursued in simple corpulence. Katabolism must be made as easy as possible for the tissue cells, as this affection is primarily katabolic.

Deutsche medizinische Wochenschrift.

March 30, 1911.

Decapsulation of the Kidneys for Uremia.—Apropos of Zondek's article in the concurrent number of the *Berliner klinische Wochenschrift,* we relate as a pendant the report of Gümbel, which concerns the relief of medical nephritis by surgical operation. Edebohls incidentally urged his procedure in cases wherein it was not strictly indicated, such as acute nephritis and eclampsia. In other words, uremia, irrespective of cause, was an indication. Edebohls had the merit of calling the attention of surgeons and physicians to the efficacy of his operation in acute uremia, as it is seen by surgeons and obstetricians. The author had thus broken into the domain of both physicians and surgeons. The physician's policy was "let alone," as far as surgical procedures were concerned; while the surgeons were concerned chiefly with conditions due to stone, etc., and mostly unilateral (surgical kidney). The author cites a case of acute toxi-infectious nephritis occurring in the course of rachitis in a child. Acute uremia was impending. He therefore practised decapsulation of the kidney on one side, it being necessarily a bilateral affection. There was rapid improvement, but no resolution of the underlying nephritis. Hence the intervention is in such cases a temporary one to avert impending uremia.

General Remarks on the Physiology of the Vegetative Nervous System.—Müller refers to the fragmentary character of our knowledge of this subject. Given that such a system of association exists, how would it be expressed under irritation? A peripheric sensory irritant would be required, such as is seen in the action of the light on the pupil, or of conjunctival irritation on the tear ducts. Instances of this kind of vasomotor reflexes are common enough in systematic works. Corresponding deeply placed ones which involve the bile ducts, ureters, etc., are known by inference only. We have no real knowledge of such reflexes, nor of those believed to reside in the heart. In addition, we have only a speculative knowledge of the action and products of alleged internal secretions. It appears probable that certain causes acting through the sympathetic systems upon ductless glands, etc., set free products which are in themselves powerful activators of organs. The sympathetic system is involved in some way in the production of pain. Thus during the latter the pupils dilate, the salivary glands secrete, the heart acts more rapidly, etc. Pawlow has shown that in or near the stomach pain causes abolition of gastric secretion. Surgical work on the peritoneal cavity shows that peristalsis may also be thus arrested. This inhibition seems to be accomplished through the splanchnic. Further the stimulus may come from a remote quarter—the skin, encephalon, etc. But in all such cases there need be no actual pain felt; *i.e.* the pain is subconscious. The spine is believed to be the intermediary in all such reflexes. Beyond these, certain sympathetic activities are due to the action of the encephalon alone. In these activities will and consciousness play no part, yet the cerebrum must be implicated. Here belongs the emotional sphere—blushing, pallor, crying, sweating on the brow, and many similar effects. This sort of physiology has been carried out in full for animals, from which every impulse is said to proceed from the brain alone (Bechterew). This view leaves no room for anything but purely cerebral activity, yet in mankind the facts seem otherwise. If we follow the analogy, we must conclude that there is a cortical center for the heart, and, in fact, for every part of the body. Independent spinal centers are, of course, well known, including the great number seated in the medulla. The double, antagonistic action of such centers is also well understood, and this double action is purely subcortical in character. It does not originate in the psyche, but the psyche may modify it. We naturally attribute to the encephalon what should often be ascribed to the medullary centers. Much of the double antagonism in physiology arises from these medullary centers. The pupil, salivary glands, etc., illustrate this duplex attitude. This applies also to certain antagonisms in the arteries and vasomotor nerves. The great problem at present is to determine when and how the psyche can modify all these subcortical centers. The body does very well upon an automatic, subconscious basis. To know the range of extent of the psyche over these processes would involve writing the history of the human race.

Functions and Utility of the Palatine Tonsil: Study of Its Physio-Pathology.—Gabriel Higuet considers from a scientific side the theories as to the utility of the palatine tonsils. The normal tonsil is one that has never been the seat of inflammation, and one will eventually atrophy. After repeated attacks of inflammation it becomes permanently hypertrophied and its utility is then questionable. After discussing the various theories of the tonsillar functions, some of them fanciful, others scientific, he gives two that are worthy of thought. One is that the tonsil is an organ of defense, by means of the formation of leucocytes which are continually carried to the surface by the lymphatic fluid in the vessels; this is applicable to the healthy. The other is that they are a cause of infection by absorption of tonsil poisons; his theory seems applicable only to the pathological tonsil. At present it is impossible for one to affirm or deny the utility of the organ.—*La Policliniquc.*

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Fifth Annual Meeting, Held at Albany, April 17, 18 and 19, 1911.

THE PRESIDENT, DR. CHARLES STOVER OF AMSTERDAM, IN THE CHAIR.

(Special report to the MEDICAL RECORD.)

HOUSE OF DELEGATES.

Monday, April 17—First Day.

President's Address.—Dr. CHARLES STOVER, in opening the meeting spoke of the great loss that the Society had sustained in the death of its President, Dr. Charles Jewett, and of four of its ex-Presidents, Drs. William S. Ely, Willis Goss McDonald, William Warren Potter, and James D. Spencer. He praised the work of the Committee on Legislation not only for their constructive work but for their care in guarding the public from legislation that in some instances could only be characterized as foolish. He spoke of the advantages of a nearby laboratory to the practitioner and urged to energetic effort in effecting and carrying out the plans for a system of county laboratories. He also recommended that funds be asked for to enable the Boards of Health to take over the tuberculosis dispensaries which had been started by the Charities Organization Society and other philanthropists.

Report of the Secretary.—Dr. WISNER R. TOWNSEND presented this report which showed that the membership of the Society was 6,370 on December 31, 1909 and 6,681 on January 1, 1911. The increase in membership in the County Societies in 1910 was small. It was hoped that renewed efforts would be made to bring into affiliation the large number of eligible physicians who did not as yet belong to any county society. The experience of five years since amalgamation had shown that each year the Society gained not only in numbers but in importance and influence.

Report of the Treasurer.—Dr. ALEXANDER LAMBERT submitted this report which had been certified by a public accountant and showed a surplus in favor of the Society of over ten thousand dollars,

Report of the Committee on Publication.—This committee reported that the expense of publishing the Journal had exceeded the revenue by $3,514. This was due to the dropping of advertisements of medicinal preparations not approved by the Council on Pharmacy and Chemistry of the American Medical Association.

Report of the Committee on Legislation.—This committee reported that during the year 1910 about two hundred bills relating to Medicine, Public Health, and Sanitation were introduced into the Legislature, nineteen of which became laws. In accordance with a resolution passed by the House of Delegates at its annual meeting in January, 1910, they had had laws of 1818 and 1819 relative to the incorporation of medical societies repealed.

Report of the Committee on Experimental Medicine.—This committee, of which Dr. J. D. BRYANT was Chairman, reported that in co-operation with the Committee on Legislation and with public-spirited men throughout the State they had labored successfully to prevent the passage by the Legislature of 1910 of two bills relating to experiments on living animals. There was no doubt that this contest would be renewed each succeeding year and every member of the profession should regard the controversy as a personal one. Each member could aid in a marked degree by explaining to his legislative representative the great importance of animal experimentation as related to the past, the present, and the future benefits to the human race.

Dr. SIMON FLEXNER made an appeal to the Society to do all that it could to prevent the appointment of a Commission for the purpose of investigating animal experimentation. While he did not think the sentiments of the antivivisectionists had aroused people generally, it should be remembered that many were credulous and easily influenced and it was the duty of every physician to enlighten his clientage on this subject and to explain the extraordinary exaggeration of these agitators. Dr. Flexner related how the British Parliament, thirty-five years ago, had been led to institute a commission for the purpose of investigation, and while the profession and medical students had been exonerated from the alleged charges of cruelty, the outcome had been a police surveillance that had hampered medical progress in that country. A commission must not be accepted; it would be the first piece of antivivisection legislation in this country and a blot on the State.

Report of the Counsel.—Mr. JAMES TAYLOR LEWIS, in his report said that the success of organized malpractice defense could not be better summarized than by the statement that in the beginning of this effort thirty cases were brought in one year. During the year 1911 but seventeen actions were begun. It was gratifying to know that the malpractice defense initiated in this State was daily gaining in national importance. Sister societies of various States were becoming imbued with the determined fight made against blackmail here, and the medical profession was fast coming to realize how important it was that its members should stand shoulder to shoulder in repelling these attacks. In Mr. Lewis's opinion the most important litigation during the year was relative to an action brought against two physicians alleging that because of their negligent and careless examination the plaintiff had been committed to the insane asylum. The case resulted in a verdict of $25,000 against the physicians. After the verdict had been rendered the papers were transferred to the State Society and its counsel for appeal. The main question tried by the jury was whether the patient *was insane* or not, while Mr. Lewis believed the only question which should have been tried was whether or not the doctors *had properly examined* the patient. An appeal argued before the Brooklyn Appellate Division resulted in a decision setting aside the former verdict and granting the defendants a new trial. Had this verdict been allowed to stand examiners in lunacy all over the State would hardly be willing to certify to the insanity of any person, and the public would have been endangered accordingly.

Report of the Committee on Public Health.—Dr. JOSHUA M. VAN COTT, Chairman of this committee, reported what was being done by State authorities and private organizations in their endeavor to educate the public to a greater degree of intelligence regarding personal and community hygiene, and urged that ample funds be provided by the State and other authorities to create special bureaus and to push the work further and further. They felt that the most pressing need in the Empire State was a well organized system of county laboratories equipped for the demands of modern diagnostics. They had prepared and submitted a plan whereby such a system of laboratories could be put into operation. These laboratories should be centralized in the State Board of Health and the Commissioner thereof should be in control and responsible for them and their working staffs.

Report of Committee to Consider Question of Increasing Interest in the Society.—This committee, in making suggestions for increasing the interest in county societies, advised the following: Improved programs. The post-graduate course as recommended by the American Medical Association. One meeting a year on public health matters under direction of the State Board of Health. At least one reader a year from a distance. One or more clinical meetings a year. Demonstration by bacteriologists

and pathologists with specimens, lantern slides, etc. Finally, that they should have high ideals; be liberal yet firm in the maintenance of a high ethical standard; educate the public; be a power for good in the community, and not be ashamed of the county society, but make it better.

Report of Committee to Consider Dr. Stover's Resolutions Regarding Nurses' Training Schools.—After having made a careful study of the requirements for admission to training schools and requirements necessary to obtain the degree "R. N.," and a consideration of the effects of the "Nurses' Practice Act," the committee concluded that the State had undertaken to raise to the rank of the profession a vocation that was of necessity subordinate to that of medicine. They were of the opinion that the State should recognize the nurse problem as an experimental one, to be regulated at present by wise administration rather than by legislation.

The Lucien Howe Prize.—Dr. A. Jacobi announced that the Committee on Award had given the prize to Dr. Homer Erastus Smith of Norwich, N. Y., for a paper on "An Improved Method for the Extraction of Immature Cataractous Lens."

Resolutions.—The Board of Trustees of the American Medical Association presented a request for the passage of resolutions providing that every member of a county society should be *ipso facto* a member of the State society, likewise every member of the county and State society should be *ipso facto* a member of the American Medical Association. It was resolved that the foregoing request be referred to a committee of five appointed by the President to be considered and reported on at the next annual meeting. The following were presented:

Resolutions urging that proper steps be taken to prevent the antivaccination bill now before the Legislature from becoming law.

Resolutions requesting that the Board of Regents change the requirements for admission to medical colleges to one year in college or its equivalent, including chemistry, physics, and general biology, and that they should make an investigation for the purpose of finding out how many internships in hospitals were available for recent graduates with the idea of adding one year in a hospital to the regular medical course.

A resolution expressing to the Legislature the feeling of loss to the profession sustained in the burning of the State Library and requesting that funds be appropriated to replace it as far as possible.

A resolution providing that the Society should endeavor to establish some standard for the education of midwives.

A resolution urging that an effort be made for the repeal of the law permitting the licensing of opticians, and that a request be sent to Columbia University asking that the course in Optometry be abolished.

Tuesday, April 18—Second Day.

Election of Officers.—The following officers were elected to serve during the coming year: *President*, Dr. Wendell C. Phillips, New York City; *First Vice-President*, Dr. Peter W. Van Peyma, Buffalo; *Second Vice-President*, Dr. William Francis Campbell, Brooklyn; *Third Vice-President*, Dr. Piffard R. Hervey, Oswego; *Secretary*, Dr. Wisner R. Townsend, New York City; *Treasurer*, Dr. Alexander Lambert, New York City; *Chairman of the Committee on Scientific Work*, Dr. L. H. Neuman, Albany; *Chairman of Committee on Public Health*, Dr. J. M. Van Cott, Brooklyn; *Chairman of Committee on Legislation*, Dr. F. C. Busch, Buffalo; *Chairman of Committee on Arrangements*, Dr. J. W. Nellis, Albany.

The following were elected *delegates* to the House of Delegates of the American Medical Association: Drs. A. T. Bristow, Brooklyn; J. W. Flemming, Brooklyn; Wesley D. Mulligan, Rochester; Edgar Vander Veer, Albany; E. E. Cornwall, Brooklyn, and Henry L. Elsner, Syracuse. As alternates the following were named: Drs. S. W. S. Toms, Nyack; A. Walter Suiter, Herkimer; W. B. Habidge, Ogdensburg; J. MacEvitt, Brooklyn; W. W. Strang, New York, and O. Pfaff, Oneida.

Meeting Place.—The next meeting of the Society will take place in Albany beginning on the third Tuesday in April, 1912.

SCIENTIFIC SESSION.

President's Address.—Dr. Charles Stover considered the present condition of medical education in this country and the outlook for the future. The report of the Carnegie Foundation was largely responsible for the increased interest in this subject, though an evolutionary movement had been in progress within the profession for a long time. He believed that overcrowding in the profession and the existence of poorly equipped medical schools would eventually solve itself through the working of the law of the survival of the fittest. The State Board of Examiners had justified its existence and in the future its work would be of even greater importance and responsibility. He spoke at length of medical education and suggested that a History of Medicine similar to Histories of Law and Theology would aid in simplifying work for the medical student.

Studies on a Local Hematological Factor in the Causation of Uterine Hemorrhage.—Dr. Arnold Sturmdorf of New York read this paper. He suggested that the terms hemorrhagia and metrorrhagia be discarded as devoid of relative significance; the same causes produced excessive menstruation, intermenstrual hemorrhage, or both; menorrhagia frequently merged into metrorrhagia, making a clinical distinction between them impracticable. He divided uterine hemorrhage into two classes, namely, cases presenting a cause and those evidencing no cause for the excessive bleeding. The first class embraced the routine gynecological, hematopathic, and circulatory concomitants of uterine hemorrhage; the second class revealed those cases occurring during the adolescent and preclimacteric period in which no cause for the bleeding was in evidence. This latter type formed the subject of the study and represented the condition described as and attributed to uterine hypoplasia, uterine fibrosis, uterine arteriosclerosis, etc. Among the histological abnormalities involving the uterine structures depicted by investigators as explanatory of the hemorrhage, Sturmdorf upheld Theilhaber's findings of congenital and acquired muscular deficiency as probably embodying a contributory factor in producing the hemorrhage and adopted Theilhaber's terms *hypoplasia muscularis uteri* for the adolescent forms and *myofibrosis uteri* for the preclimacteric condition. Sturmdorf showed that none of the pathological changes recorded exhibited that uniform regularity of association with the hemorrhage essential to establish the relationship of cause and effect; on the other hand he pointed to the constancy in the occurrence of *the* one feature typifying the cases under consideration, namely the absence of coagulation. He utilized the analogous non-coagulability normal to menstrual blood as the basis for his investigation and showed that the hypotheses hitherto accepted as explanatory of this phenomenon were no longer tenable. After a critical review of the literature on the physiology of coagulation in general and menstrual incoagulability in particular, he detailed his experimental and clinical observations and concluded that the hemorrhage in hypoplasia and myofibrosis uteri resulted from the same or similar form of inhibited coagulation. He summarized his findings as follows: Whatever future investigation might re-

veal as to the exact nature of the inhibitory element in question, the facts established by the present study might be summarized as follows:

(1) The general circulating blood during the menstrual period and in the hemorrhagic conditions here considered showed normal coagulative properties. (2) During menstruation and hemorrhage the endometrium received normally coagulable blood from the general circulation and gave vent to this blood in a non-coagulable state. (3) The non-coagulability in the menstrual and hemorrhagic blood disclosed an identity in experimental and clinical manifestations differing only in degree. (4) Under the given conditions the endometrium exercised a function capable of rendering coagulable blood non-coagulable. (5) This function was due to the presence of an inhibiting substance generated *in loco* and was not the result of a dialytic process, as suggested by Cristae and Denk. (6) The non-coagulable blood contained all the essentials to coagulation; nevertheless this blood was capable of inhibiting coagulation in normal blood taken from the same individual, all of which tended to warrant the assumption that an inhibitive element, preventing coagulation, probably augmented in activity by contributory structural abnormalities, presented a local causative factor in the production of uterine hemorrhage.

Operation for Adherent Retrodisplaced Uteri by Shortening the Round Ligaments Through the Inguinal Canal after Abdominal Section Through the Transverse Incision.—Dr. Le Roy Broun of New York City read this paper in which he reviewed the reasons why some of the operations employed for the correction of adherent retrodisplaced uteri had proved unsatisfactory and said that he had adopted with some modifications the operation described by Reuben Petersen before the American Gynecological Society in 1906. This operation had been so satisfactory in his hands that he had practically discarded all others. He made a horizontal incision after the manner of Pfannensteil, but lower down in the area of the growth of the parts. The fascia was divided horizontally and dissected free from the muscle above and below. The recti and pyramidoli were then separated. Through this opening the peritoneal cavity was entered, adhesions severed, and all ordinary pathological conditions dealt with. Before closing the incision the fat in one angle of the wound was dissected free from the fascia up to the external abdominal ring, which was easily located by palpating the pubic spine. The skin was retracted beyond the ring, the round ligament grasped and withdrawn until the inflection of the peritoneum came into view; this was not stripped from the ligament. The external abdominal ring of the opposite side was exposed in the same manner and the ligament withdrawn. Dr. Broun said it was his custom to make sure that no loops of intestines lay over the fundus of the uterus. The ligaments were stitched to the pillars of the ring. For drawing out the ligaments he used clamps in which the sharp edges of the serrations had been filed off and the edges rounded; this avoided lacerating the ligaments. In dressing the wound full pressure should be applied over the site of the operation. This operation was ideal in that, first, there were no abnormal implantations of the uterine supports made or false adhesions brought about; second, the strongest part of the round ligament was utilized.

Dr. H. P. Jack of Canisteo stated that, although his personal experience with suspension had been very gratifying, he believed it should be abandoned during the child bearing period. He objected to Dr. Broun's operation because it might result in pressure on the nerve passing through the inguinal ring, which would cause pain. Dr. Mayo now did the Noble operation, fastening the ligament behind, and this seemed to be successful. The Gilliam operation he could not commend too highly, with the modification of taking up the excess of the peritoneum, closing the space where the ligament might slip through.

Dr. Broun agreed that if the nerve was injured Dr. Jack would be right, but such an injury was unnecessary. The Gilliam operation gave an abnormal implantation of the round ligament.

Dr. Jack stated that he used a modification, fastening the round ligament under the fascia instead of on top; then no hernia occurred.

Concerning the Treatment of Bladder Tumors with the High Frequency Current of Oudin.—Dr. Edwin Beer presented his paper in which he reported in full the two cases mentioned in a preliminary report published in the *Journal of the American Medical Association*, May 28, 1910. He described the technique by which the electrode was introduced into the bladder through the cystoscope. He had treated successfully five cases aggregating nine tumors and had had one death which seemed to be due to endocarditis, though possible embolism following the treatment was responsible. In summarizing the review of the histories of the six cases he concluded that the high frequency current of Oudin exerted a decided influence upon papillomata of the bladder. Two cases in elderly women were resolved in thirteen and one-half minutes divided into eight séances. A third case had required nine séances covering thirty-four minutes. The experience of other surgeons with this method had been as satisfactory as his. The base of the papilloma could be thoroughly destroyed. The dangers incident to this treatment were severe burning or perforation of the bladder wall, both of which could easily be avoided with care. It was too soon to pass judgment on the value of this treatment but it promised more than operation.

Dr. Broun of New York City said that it was remarkable how tolerant the bladder was after such treatment, but it should be left to those accustomed to use it.

Dr. Victor C. Pedersen of New York City said that it was too soon to form any opinion of the value of this method as most growths of the bladder were malignant if given time enough. They were not warranted in passing judgment within from three to five years.

Dr. Wilhelm Gaertner of Buffalo had treated five cases with apparent success, two of them over seventy years of age and having severe hemorrhage.

The Diagnosis and Surgical Indications of Duodenal Ulcer.—Dr. James Taft Pilcher of Brooklyn read this paper. He drew attention to the fact that it was practically impossible to differentiate in all cases between uncomplicated ulcers of the gastric outlet and those in the duodenum, but stated that the purest type of symptom complex was that evidenced by duodenal ulcers, stating that four considerations were preeminent in the very great majority of cases: (1) The *chronicity* of the complaint; (2) the *periodicity* of the exacerbations of stomach distress; (3) the *pain*, its characteristics and time of inception, and (4) the *control of the pain* by the ingestion of food or alkalies. Dr. Pilcher then took up the analysis of 156 cases which he had personally examined, and in all of which ulcers of the duodenum had subsequently been demonstrated at operation. The average duration of the symptoms was 12½ years in this series. The complaints of the patients were in the main that the attacks of epigastric distress would come on at varying intervals of time, from several months to several years, without any obvious causative factor, and that after continuing for days or weeks would suddenly experience a relief from their subjective symptoms; that in practically all of the cases early in the course of the disease relief from their distress invariably followed the intake of food or alkalies. The time for the recurrence of their pain averaged between three and four hours after meals, and after retiring at night; the pain recurred regularly and was quite definite. Eighty-four per cent. of the

cases were in the male. He then stated that he believed that analysis of the stomach contents was not diagnostic, but in many instances was suggestive, and that the deductions therefrom should be considered merely as confirmatory. He had performed complete gastric analysis in each of these cases, the average acidity being between 75 and 80. There was also present in the majority of the cases a hypersecretion of this hyperacid fluid. The duodenal bucket had been employed in twenty-five instances, and the author concluded from his findings that the results from its use should be considered confirmatory rather than diagnostic. Considering the question of operative interference in cases presenting symptoms suggestive of duodenal ulcer, he stated that there was no ground for conflict between the surgeon and physician in this field, as those cases which have been submitted to operation had been treated medically for an average of 12½ years without any permanent relief. The speaker then pointed out the small operative mortality ensuing from surgical interference, which is more than offset by the tremendous percentage obtained in cases which had perforated; he drew attention to the fact that the present treatment of chronic appendicitis was to urge operation, and suggested that procrastination in dealing with a condition which contained potential elements many times more dangerous should be taken into consideration in advising patients as to the probability of future health if duodenal ulcer was allowed to continue unrelieved. The important factors indicating operative interference were stenosis, which was readily demonstrable by the stomach tube, a palpable mass in the epigastrium which was present in fifteen of the cases considered; hemorrhage where it continued steadily, but in small quantity, and which might be recognized by the gradually developing secondary anemia; and, finally, intractability of the condition to medical means, evidenced by the attacks becoming more frequent and lasting longer, and the pain becoming more severe and its relief accomplished with greater difficulty, with continuous discomfort, where previously it had been periodical. The condition generally caused the patient to lose weight and strength.

The New Thoracic Department of the German Hospital of New York City.—Dr. Willy Meyer of New York City described this departure in surgery, which he stated was new so far as the United States was concerned. There were both aseptic and septic operation rooms. The aseptic operating room contained the negative differential pressure chamber, 8 x 8 x 16 feet in size, and within the same a positive differential pressure cabinet. The object of both vaults was the same—to adjust the pressure of air in a patient's lungs so that they would not collapse when the lung casing was cut into, and the air pressure from outside was allowed to enter. In the positive pressure vault a large steel hood stood close to an operating table so that a patient's head could be enclosed in the hood while the body lay on the table. Compressed air tubes connected the pressure pumps with the steel hood, while a heavy rubber bandage was arranged for adjustment to the neck so that an airtight condition could be obtained. Thus the control of pressure on the head was wholly independent of that on the body. Similarly in the other vault the encased head could be left normal as to pressure, while a suction arrangement would empty the main operating chamber of a part of its air. Dr. Meyer had succeeded with animals, both in cases where air was forced into the lungs at a pressure through the nostrils and where air pressure was suctioned away from the operating table until the lungs would not collapse. The apparatus would solve the problem of thoracic surgery, which has thus far been a closed field.

Taking the Cure at Carlsbad.—Dr. Henry G. Watson of New York City gave a graphic description of his journey to this resort and described the cure, which consisted in dieting, proper baths, and rest. This treatment was contraindicated in tuberculosis, valvular disease of the heart, and atheroma.

Dr. L. F. Bishop of New York City said that he was glad to hear the contraindications to the Carlsbad treatment mentioned; they were too often overlooked. He related an instance in which the patient had arteriosclerosis and high-blood pressure and was made worse by taking the treatment.

The Bladder and Prostate.—Dr. J. F. Whitbeck of Rochester read this paper. He said that it was not his purpose to attempt to present a scientific or novel paper for the expert, but rather to give a practical view of the subject for the consideration of the general practitioner. It had been estimated that at least one-third of all men had an enlargement of the prostate gland which involved the bladder in difficulties. Owing to the obstruction offered by the increased size of the prostate, the residual urine might be sufficient to so paralyze the bladder as to cause retention. This retention might require the use of a catheter; and even a moderate amount of residual urine might be left to decompose or to deposit a sediment from which a calculus could be formed. The properties of the urine might be changed by concentration and by food and drink and so increase the congestion of the prostate and the irritability of the bladder. It was important to have the urine as bland as possible, to regulate the diet, and the time and frequency of urinating in order to preserve the capacity and contractility of the bladder. Whatever view might be taken of a radical operation there were cases in which some grave organic disease forbade surgical treatment and extirpation of the prostate gland. Alcoholic beverages, charged waters, coffee in quantity, especially at night, much milk, acid fruits, or much meat increased the urine or rendered it acid. A patient should be taught to lengthen the intervals of urinating, and to be as careful and deliberate as possible while passing urine in order to expel as much as possible of the residual urine. Water was the best diuretic and would do more to make the urine bland than any agent they had. The risks of catheterism could not be overestimated. The anterior urethra should be cleansed by syringing with a 1-10,000 solution of bichloride of mercury. The glans penis and the meatus should be sponged with a bichloride solution. The catheter should be boiled and lubricated with an aseptic material. The hands of the operator should be clean. A number eight soft rubber catheter which had been boiled in a solution of boric acid was recommended. Such an instrument might be kept in the instrument bag if it was in a sterile bottle or jar. A convenient lubricant might be composed of one part adrenalin solution with one part of a four per cent. solution of cocaine in 1-5,000 bichloride and four parts of some aseptic lubricant such as was provided in tubes by chemists. Absorbent cotton and a solution of 1-1,000 bichloride might be kept at hand for the hands of the operator and the penis of the patient. The reader did not recommend the sound in prostatic disease. The metallic catheter should not be used if a soft rubber one could be passed into the bladder and a number eight seemed to be better than a larger size. Dr. Whitbeck advised against castration for the cure of prostatic disease. Experience showed that with the patient in fair health the prostate might be removed without difficulty or danger. There were dangers in delay when the prostate might be safely removed, for cystitis, pyelitis, calculus, and other serious conditions might follow the use of the catheter and the indefinite postponement of radical treatment.

Remarks on the Therapeutics of Salvarsan.—Dr. S. J. Meltzer read this paper, placing special emphasis upon the scientific principles which formed the basis of Ehrlich's experiments, in contrast to the use of mercury, which was a remedy hit upon by chance. He described the steps by

which Ehrlich evolved salvarsan and the brilliant results that had been obtained. He believed that this discovery might be the means of raising therapeutics, which had fallen into disrepute, to the dignity of a science.

The Indications for Salvarsan in Syphilis.—Dr. S. Pollitzer read this paper and concluded that salvarsan was indicated: 1. In the early and active stage. 2. In external gummatous lesions. 3. In lesions of the eye or throat. 4. In painful lesions of the bones; it was most efficacious in relieving pain. 5. In syphilitic cachexia. 6. In cases complicated with tuberculosis. 7. In hereditary syphilis in infants. 8. In the early stages of tabes; small doses exercised an inhibitory effect. 9. Where there was intolerance for mercury. 10. Where mercury did not change a positive Wassermann reaction to a negative one. Every patient included under these ten heads should have at least one dose and should also receive the fullest and best course of treatment with mercury.

An Analysis of the Clinical and Serological Results Obtained in the Treatment of 175 Cases of Syphilis with Salvarsan.—Dr. John A. Fordyce cited cases which had been treated in the primary stage with a single dose of the remedy in which the reaction became negative and no secondaries developed, one case having been observed since last October. He reported on two other cases one with severe rupial lesions and the other one with multiple initial lesions and secondaries. The patients received minimum doses of 0.3 gm. intramuscularly, no relapse had taken place up to the present, and both now had a negative serum reaction, although no other form of treatment had been employed. In view of recurrences and the difficulty of influencing the Wassermann reaction with a single dose he advised a repetition at intervals of from one to four weeks supplemented by an active mercurial course. He emphasized especially the value of this drug in malignant syphilis in which its effects were nothing short of miraculous. From his study of lues extending over a period of thirty years he could without exaggeration say that he had seen more rapid and brilliant results from salvarsan in this class of cases than he had ever seen from the administration of the classical drugs. It was possible there was here a different strain of organisms more easily influenced by salvarsan than by mercury and potassium iodide. The lesions healed rapidly, a decided increase in weight occurred within two weeks and the temperature often accompanying these cases became normal. In advanced disease of the nervous system he had noted no benefit from the administration of the drug, but had in several cases of early tabes, in one of paresis, in endarteritis of the base of the brain, and in several cases with persistent headache obtained most gratifying results. In his series of cases he counted six relapses, all after treatment with a single dose. They were periosteal lesions in a case of malignant syphilis, plantar and palmar syphilis, mucous-membrane lesions, an acute unilateral optic neuritis, and an iritis. Failures were met with in advanced tabetics and paretics and in five cases of hereditary syphilis, but three of the latter it was hardly fair to class as failures since the dose which had been administered was inadequate. Dr. Fordyce said he had had no accidents following the administration of salvarsan although he had given nearly a hundred intravenous injections. He felt that there was no more danger connected with this remedy than with other therapeutically active drugs. It was, however, necessary to observe the contraindications to its use and the greatest care should be exercised in the proper preparation of the solution and the technique of its administration. In only one case had he noted by-effects which had given him any anxiety, viz., the development of convulsions and hemiparesis three days after an intramuscular injection of 0.2 gm. alkaline solution to a child seven and one-half years old with an extensive gummatous infiltration of the nose and upper lip. A Herxheimer reaction in a lesion at the base of the brain was assumed as the cause of the phenomena. The child made a good recovery, and the lesions for which it was treated healed rapidly.

The Action of Salvarsan on the Wassermann Reaction. Dr. Howard Fox read this paper. His conclusions were summarized in the Medical Record of March 25.

Technique and Methods of Administration of Salvarsan.—Dr. Homer Swift described the method of preparation of the salvarsan solution and how it should be employed, using charts. The results of his work were summarized in the Medical Record of March 25.

A Few Plain Truths About Salvarsan.—Dr. William S. Gottheil of New York City read this paper in which he stated that salvarsan was valuable in certain cases as an additional weapon in their armamentarium but that it did not accomplish the marvels attributed to it. It did not cure any more than mercury. It was powerful in combating symptoms. Symptoms of the persistence of syphilis appeared more frequently after treatment with salvarsan than after treatment with mercury. Cases recently infected were the only ones by which its efficacy must be estimated. The disadvantages and dangers and the large series of deaths warned them that the remedy was not one for the profession at large. Mercury was still the antisyphilitic for general use. The latest advice from high places was to use salvarsan first and then to recur to mercury. Cases of idiosyncrasy in which mercury could not be borne were not as frequent as some would have them believe since the discovery of salvarsan. Salvarsan in his experience had been efficacious in the early type of syphilis. The symptomatic effects were equal to those of mercury and sometimes failed. Salvarsan was as useless as mercury in late cases. Salvarsan was useful in persistent lesions, in mucous patches, and in cases not permitting of long medication. That was in rare cases where immediate action was needed, but it was not indicated in ordinary cases.

The By-Effects of Salvarsan.—Dr. James Winfield of Brooklyn said that the by-effects were local, organic, and general. The local ones were pain, infiltration, sloughing, necrosis, especially with the subcutaneous method of injection, swelling of the lymphatic glands in the neighborhood, scarlatiniform eruption, icterus, herpes zoster, and urticaria. Among organic effects were pulmonary embolism and pneumonia, cardiac and circulatory disturbances, hemorrhagic nephritis, and acute necrosis of the convoluted tubules. There were no serious effects on the gastrointestinal tract. Affections of the cerebrospinal system seemed to increase after its use, also ocular involvement and aural effects, which were often transitory. It might be that they had been more keen to note these nervous manifestations than formerly. The vital organs should be carefully examined before this remedy was used for any deviation from the normal.

Dr. George Fox said that salvarsan would probably never fulfill the hopes that some had entertained, but in some cases it had accomplished what mercury never did. He spoke of the use of salvarsan in leprosy and psoriasis, and related cases where it had seemed to be of some value.

Dr. B. Lapowski of New York had had experience with 120 cases and spoke forcibly against its general use. He summarized his remarks by saying "What 606 does mercury does. What 606 does not mercury does."

Dr. Victor C. Pedersen sounded a note of warning in regard to the intravenous injection, which was a serious surgical undertaking, and related a case which nearly proved fatal because of heart complications.

The Relationship of Tabes to General Paresis—Are They the Same Disease Differing Only in the Situation of the Lesion?—Dr. Edward D. Fisher read this paper.

He stated that both diseases were parasyphilitic or metasyphilitic manifestations of a primary syphilis. Tabes in its classical or typical form rarely or never presented mental or cerebral symptoms characteristic of general paresis. Tabes was a chronic progressive disease confining its lesions to the posterior spinal nerve ganglion, posterior nerve roots, posterior columns, and meninges of the spinal cord and the cranial nerves, especially the oculomotor and optic. General paresis was a disease comparatively acute as compared with tabes, running its course in three years when the former might continue its course for twenty years or longer. Its lesions were chiefly cerebral, involving the meninges and cerebral neurons, to a less degree the cranial nerves, as the optic nerve and the superior nucleus of the oculomotor nerve. The spinal lesions were rarely systemic in type, that was, were rarely if ever confined either to the posterior columns or the lateral, but fell under the head of a diffuse or combined sclerosis of the spinal columns. In 100 cases of general paresis of cerebral and tabetic type but one gave anything resembling a classical case of tabes. Clinically the cases observed by the writer in hospital, dispensary, and private practice, which approached each other in a minor degree, essentially differed in intensity in the more marked symptoms. In tabes the ataxia was much more extreme, the lightning pains and crises much more frequent and disabling, the ocular manifestations, such as ptosis, strabismus, optic artophy, much more constant than in general paresis whether of the cerebral or tabetic type. It was impossible to believe that a disease essentially spinal in its symptoms and pathology and lasting usually at least twenty years could be the same, differing only in the site of its lesion, as a disease limited usually to three years, or even in the unusual or extreme cases to ten years, and whose pathology was essentially cerebral.

The Nervous Woman.—Dr. Edward B. Angell of Rochester read this paper. He said that nervousness was not an imaginary ailment, although it might be in truth a disorder of the imagination. It was too often regarded as a manifestation of neurasthenia, which term, by the way, had been very much abused. This was a true exhaustion neurosis and had definite symptoms of that condition, while nervousness was usually due to a toxemic state, an altogether different matter. Nervousness was characterized by self-attention, self-feeling, an exaggerated self-consciousness, that developed a train of hypochondriacal ideas, rather than a loss of neural energy. However, the classification was somewhat arbitrary. Nervousness he had found as common in men as in women. Heredity, education, and environment had much to do with establishing a soil favorable for the development of this condition. Yet they were of less significance than in the graver disorders, neurasthenia and hysteria. Nor were pelvic disorders in women as intimately associated as causal influences with nervousness as was usually supposed. The condition, in his experience, based upon the records of over 1000 private cases carefully noted, depended very largely upon a toxemia of the nervous system, due to disturbances in metabolism. The excessive use of proteid foods, rich in nitrogen, with inefficient oxidation and elimination of the waste products and intestinal dyspepsia had caused from 70 to 80 per cent of his cases. Most nervous people, he found, had indoor occupations. A large proportion confessed to the free use of proteid food. The symptoms dominant, and only those were mentioned which occurred in over 50 per cent. of the cases, were, in the order of their frequency, "a weariness and a good-for-nothing feeling," a sallow complexion, especially of the abdomen, usually associated with a yellow fur on the tongue; self-consciousness; irritability; depression of spirits and forgetfulness. In two-thirds of these patients there was abdominal distension from fermentation. Other common symptoms were vertigo, backache, inertia, and apprehension of future ill. In the routine examination of the urine of these cases he noticed that a marked pigment line, dark brown or red, corresponding to the white albumen ring in Heller's test, developed at the point of contact with the underlying nitric acid. This pigment ring was very distinct in about 70 per cent. of his cases, while the urine itself was persistently or highly acid in a somewhat smaller proportion. The relationship between the urinary reaction and the disturbance of metabolism was emphasized by the results of treatment. A correct dietary, allowing only a limited amount of proteid food and sugar, alone would in time result in clearing up the nervous symptoms and in causing the pigment line and acidity to disappear from the urine. This result could be materially hastened by the use of the salicylates and alkalies. A thorough physical examination was of utmost importance to insure freedom from any organic disease as, needless to remark, nervousness at times was associated with structural changes. The course of treatment must be rigid and persistent to insure satisfactory results. A large proportion of cases recovered promptly, but it must be remembered that nervous people were difficult to manage and some would require isolation from their environment and constant oversight for a period of two or three months. Moral agencies, mind healing, hypnotic suggestion, or even Christian Science, so called, might be efficient, but were not sufficient. The underlying physical condition must be remedied, rather than the sufferer taught to disregard her misery. Correct the diathesis and the other influences were seldom needed.

The Clinical Observations of Cardiac Arrhythmias from the Modern Standpoint.—Dr. Walter B. James read this paper, which was illustrated by radiograms. He stated that his observations had been made at the Presbyterian Hospital in New York City, where they had a fully equipped heart station. He described the electrocardiograph and the method of taking tracings. He divided arrhythmias into two classes, those in which the arrhythmias were strictly according to rule, *i. e.*, where there was a fixed interval between the irregularity and the extra systole to which it belonged. He called this group rhythmical irregularities. The second group belonged to those cases in which the irregularity followed no fixed law whatsoever. This distinction could be made by any practitioner by listening with the ear and simultaneously noting the pulse with the finger. All irregular hearts were due to fibrillation of the auricle. They had formerly considered absolutely the irregular pulse the one offering the worst prognosis, but this was not the truth. The absolutely irregular pulse was due to auricular fibrillation and might be associated with a good ventricle, and in this case they had in digitalis a control for the auricular fibrillation. On the other hand, the rhythmically irregular pulse was not so amenable to treatment. There were different divisions of the group of regular arrhythmias, but the most important were the extra systoles. Digitalis should be pushed at the onset of extra systole, but upon the appearance of the bigeminal pulse it should be discontinued.

Dr. L. F. Bishop suggested that by observing carefully the venous pulsations in the neck and at the same time feeling the pulse they could recognize these conditions by sight and touch. It required but little training to do this.

Vaccination in Army.—Dr. John Van Hoff, Medical Corps, Fort Jay, New York, read this paper which brought to bear a convincing array of statisical proof in favor of vaccination and revaccination.

Wednesday, April 19—Third Day.

Arteriosclerosis, or "The Cardiovascular Disease."—Dr. Louis Faugeres Bishop of New York read this paper. He said that every worker in the field of general medicine

and of circulatory disease in particular must have felt the need of a name to convey the idea of disease of the heart, disease of the blood-vessels, arteriosclerosis, and the correlated conditions of autointoxication, neurasthenia, kidney degeneration, and so on. He proposed to describe that clinical syndrome as "The Cardiovascular Disease," just as fibrillation of the auricle had been recently described as "the irregular heart." This was a name that could be readily understood by all physicians and yet did not imply anything more than that it was the commonest form of disease of the heart and blood-vessels. He considered arteriosclerosis a bad term because it had become associated with a particular pathology of the blood-vessels and had drawn the attention away from the general distribution of the disease. It was a toxic degeneration of the circulatory organs of gradual onset and slow development, often leading in the first instance to neurasthenic symptoms and diminished blood pressure, this being accompanied by indicanuria: and later developing albuminuria and variable blood-pressure; a diffused, soft systolic murmur heard to the left of the sternum and lower down than the hemic murmur; after that followed protein intolerance, high blood-pressure, and definite changes in the arteries and heart of a structural nature. The disease terminated in the typical picture of Bright's disease, with contracted kidney, dilatation of the heart, anasarca, and almost complete protein intolerance. The cause of "the cardiovascular disease" was, he believed, intestinal putrefaction. At least, in his experience, covering the observation of more than 40,000 specimens of urine, intense indicanuria had always been present, except in some advanced cases in which the original cause was not active and in which the suffering was due to the acquired structural changes. The relation between the naturally present bacterial activity of the intestine, the absorption of indol, phenol, skatol, and so forth, and disorder of the digestive organs might be left for the laboratory to determine, but, clinically, indicanuria could be used as an index of the condition.

Dr. Edward B. Angell said that this was quite confirmatory of what he had said in relation to nervous people. One could not always tell whether the condition of these patients was due to autointoxication or to faulty excretion of nitrogen by the kidneys. He favored treating the kidneys by means of alkalies rather than by placing too much reliance on purgatives.

Dr. John M. Swan was opposed to a change in the nomenclature as suggested by Dr. Bishop. The degenerative changes under consideration were due to many causes, but he thought overeating of both proteins and hydrocarbons was largely responsible. A low blood-pressure indicated an early stage of the disease. He urged his hearers to search for some more definite method of reporting on the amount of indican found in the urine.

Dr. H. Schoonmaker of Clifton Springs was in favor of using the term cardiosclerosis for the condition, that being the term suggested by Mackenzie. He advocated the starvation treatment as a temporary measure, being careful not to carry it to the point of starving the myocardium. He recommended incandescent and sweat baths rather than the Nauheim baths.

Dr. Bishop, in closing, said that he could not agree with Dr. Angell as to the harmlessness of the alkalies. They produced an alkaline condition of the intestinal tract which was favorable to putrefaction.

The Significance and Therapy of High Blood Pressure.—Dr. J. F. Rooney of Albany gave the results of his experiments with vasodilators on blood pressure. He concluded (1) that the utility of the vasodilators was conversely apparent with the acuteness of the pathological condition; (2) that eliminative measures, hot air, carbon dioxide baths, and catharsis were of much more marked effect in the toxic group; (3) that bleeding was of great service in the acute toxic groups accompanied by dilatation of the heart, but had fallen into undeserved disuse; (4) that blood pressure determinations alone could not differentiate between the crises of tabes and intraabdominal perforations; (5) that the effect of nitroglycerin was as prolonged as that of any of the nitrite group except erythrol tetranitrate, and that its rapidity of action was as great as any and nearly as great as that of amylnitrite; (6) that the use of the aconite group as vasodilators was pharmacologically unfounded and, except in the toxemia of pregnancy with a strong heart muscle, should be entirely discontinued.

The Hydrotherapeutic Treatment of Chronic Disease of the Heart.—Dr. John M. Swan read this paper, in which he described the Nauheim method, which he used. It was claimed that the natural brine was more effective than artificial brine. The principal ingredients were sodium chloride and calcium chloride, with, after the first two baths, the addition of carbon dioxide. The results he had observed were diminution in the size of the heart, slowing of pulse and respiration, redness of the skin, reduction in the size of the liver, and increase in the flow of urine. Most theories given to account for beneficial results were farfetched, and he was inclined to believe the increased activity of the skin which lessened the resistance of the peripheral vessels had much to do with the results. Indications for the treatment were any condition in which the myocardium was not perfectly performing its normal function, following acute infectious diseases, and in debilitating and wasteful diseases, after hemorrhage, in pernicious anemia, diabetes, and after surgical operations, when there was threatened failure of compensation, in chronic valvular disease, and in organic murmurs. In cardiac murmurs it sometimes succeeded, sometimes failed. In toxic tachycardia it was of no use. In arteriosclerosis and high blood pressure the brine should be weak. It was contraindicated in nephritis, aneurysm, and advanced arteriosclerosis.

Dr. L. F. Bishop said that in all of these conditions the patients were suffering from a disturbance of tonicity of both voluntary and involuntary muscles, which was the cause of dilatation of the heart and contraction of blood-vessels and the good effects of the Nauheim treatment were due to improvement in tonicity.

Dr. Schoonmaker of Clifton Springs said he preferred the term Nauheim method rather than Nauheim baths, because diet and other treatment always accompanied it. He produced his baths by mechanical and not by chemical methods. He did not agree with Dr. Swan that one could not determine in many cases the size of the heart by percussion; one could educate the ear and touch to distinguish accurately the size of the heart, and the *x*-ray would help.

Olive Oil in Postoperative Nausea.—Dr. Clarence B. Hyde of Brooklyn presented this communication in which he recomended the administration after all operations of two ounces of pure olive oil by the mouth. It was important that it should be given just at the time when the patient began to recover consciousness, as soon as he was able to drink, but before he had recovered sufficiently to be distressed by nausea. If given at this time the patient could not remember drinking it. It usually occasioned one attack of explosive and projectile vomiting after which the patient experienced no further annoyance from this cause. Occasionally patients did not vomit the oil, but this did not lessen the good effects.

Developmental Defects of the Abdominal Viscera with Their Surgical Significance.—Dr. William F. Campbell of Brooklyn read this paper. He said that his observation in five hundred post-mortems together with his clinical

experience had convinced him that many abnormal conditions of the abdominal viscera hitherto regarded as acquired were due to developmental defects and were rationally explained on this basis. In the course of evolution from the quadruped to the biped the long mesenteries of the former had been shortened or eliminated. In the quadruped the abdominal wall acted as a hammock for the viscera; in the biped it acted as a corset. This should be borne in mind in the treatment of enteroptosia. Enteroptosia, nephroptosia, Lane's kink were developmental defects, not due to wearing corsets. In treatment of enteroptosia abdominal supports should be relegated to their proper place and gymnastics should be used to greater extent. Lane's kink was a factor in intestinal stasis, and simulated chronic appendicitis; it should be corrected by surgical procedure.

Deductions from Clinical Experience in the Use of a Polyvalent Bacterial Vaccine.—Dr. J. M. Van Cott of Brooklyn presented this paper with the idea of raising the question of the possibility of placing these vaccines where they could be used by the general practitioner who was not prepared to take the opsonic index and to make a blood examination. He used intramuscular injections giving one-half c.c. or 375 million dead bacteria. He made revaccinations at intervals of four days. The effects lasted seventy-two hours, the only adverse one being muscular discomfort. There was no evidence of clinical depression. He had treated 75 cases of infection, of which 35 were erysipelas, 18 puerperal sepsis, and the remainder miscellaneous infections. The patients were all in bad shape before the injections and most of them did well afterwards; there were two deaths from erysipelas and two in puerperal sepsis. It was better to use stock vaccines than the autogenous because they were obtained sooner and easier. Vaccination was useless in cases where the patient was swamped by toxins. In milder forms of infection the results were ideal.

Surgical Treatment of Exophthalmic Goiter.—Dr. Martin B. Tinker of Ithaca, N. Y., read this paper. He said that over fifteen years ago a medical man, R. J. Möbius of Leipzig, not a surgeon, presented some of the strongest arguments ever yet advanced for the surgical treatment of goiter. Osler, writing in the same year, 1806, prefaced his recommendations on treatment by the statement, "Medical measures are extremely uncertain," and suggested operative treatment. With the single exception of Kocher, it had been the progressive practitioners of internal medicine who have advocated the surgical measures which have proved so successful in the treatment of exophthalmic goiter in recent years. Operative treatment was the only logical treatment in well developed cases of goiter because the symptoms of goiter were the symptoms of poisoning, similar to those produced by narcotic poisons. The excessive secretion acting as a poison was produced by the thyroid. In removing a portion of the thyroid gland one removed the cause of the trouble. The overuse of tobacco caused tachycardia and weakness of the heart's action, not at all unlike the condition seen in hyperthyroidism. Excessive use of tobacco also caused nervousness, general unrest, tremor, sleeplessness, sometimes nausea, vomiting, and diarrhea. The presence of excessive thyroid secretion in the circulation has a very similar effect. No sensible man would consider it logical to treat tobacco heart or tobacco amblyopia and allow his patient to continue the excessive use of tobacco. It was just as logical to treat exophthalmic goiter with drugs without removing the source of the excessive thyroid secretion. If they were convinced that surgical treatment was the logical treatment in exophthalmic goiter, when should such treatment be advised? Operation should certainly be advised before irreparable damage had resulted to important vital organs. The greatest strain came on the organs of circulation and the nervous system but almost every important vital organ suffered in the advanced cases. One hundred and fifty-one consecutive operations without fatality were reported. These were not picked cases. Many of the patients were in extremely bad condition. With three exceptions every patient who had applied for operation had been operated upon. The three patients who were refused operation all died medical deaths in periods ranging from twenty-four hours to three weeks of the time when they were seen.

Dr. Parker Syms said the important question to be considered was whether or not the patient was being poisoned by the thyroid secretion. It was important to recognize when degenerative changes began. A good method was to keep a list of symptoms of exophthalmic goiter, to note which were present and then to keep a careful history of the case. Many things influenced the progress of the disease, fatigue, nervous strain, grief, shock, etc. When poisoning was progressive the only cure was the removal of the gland. He approved of the stage operation, but warned against removing the entire gland and the parathyroids. He had recently used a Beer's cup to draw out a cyst in the thyroid and it had proved to be a most satisfactory method.

Dr. G. T. Chase of New York City related his experience with the serum treatment, and said that it did not cure, but it controlled symptoms and enabled them to carry a patient along for a number of years without operation.

Dr. E. MacD. Stanton of Schenectady said we were living in an era of safe surgery, and strongly advocated general anesthesia in these operations on the thyroid gland.

Dr. Tinker, in closing the discussion, said one had better use good local anesthesia than slight general anesthesia, which was often no anesthesia at all. The use of the Beer's cup was an ingenious idea, and he would adopt it in the future.

Mutual Helpfulness in the Conservation of Public Health.—Dr. William A. Howe of Phelps said that the Department of Health was desirous of getting nearer to the practitioner. They wanted the physicians to know that the supplies of the department were always at their disposal, and they welcomed the opportunity of furnishing laboratory assistance, an expert diagnostician, or a sanitary engineer. He urged a further study of the antitoxin in diphtheria and an earlier and more extended use of this agent.

Dr. D. M. Totman of Syracuse also spoke of the reluctance of many physicians to use antitoxin and criticised the negligence of physicians, even those who were progressive, in reporting tuberculosis to the health department.

Dr. F. Overton of Patchogue said that if the physician was remiss in administering antitoxin they should educate the public to demand it. The Society should help the State Department in carrying out the public health lectures.

Dr. Rosalie Slaughter Morton spoke of the success that had attended the lectures given by the Woman's Committee of the American Medical Association and felt sure that by educating the public they would take the most effective means of lessening their work of preventing antivivisection and antivaccination legislation.

Malignant Tumors of the Kidney.—Dr. Henry Adsit of Buffalo read this paper. He said that these tumors might be grouped into five classes: (1) Hypernephroma, by far the most frequent and also the most difficult to diagnose early. (2) Carcinoma, a condition curiously rare. (3) Mixed tumors occurring in children, which were not uncommon. (4) Sarcoma, also a disease of childhood and practically a subdivision of the last group. (5) The

very rare condition of malignant papilloma of the kidney pelvis. The relative frequency was variously estimated at from 0.2 per cent. to 7.1 per cent. of all tumors. Hypernephroma occurred in 91 to 97 per cent. of all kidney tumors. Hypernephroma had been a pathological puzzle. Weight of evidence was in favor of epithelial origin of these tumors and that they were a malignant development of aberrant adrenal tissue. He had cut aerial sections of 241 normal kidneys and had found adrenal rests in 7 per cent. These growths were not infiltrating. Metastases took place through the veins, seldom through the lymphatics. These tumors varied greatly in rapidity of growth. He had seen them of eleven years' standing; others grew very rapidly; in one case the tumor weighed seven pounds at the end of two months. Many cases reported as carcinoma were found to be hypernephromata, or else metastases from a primary cancer elsewhere. It was most frequent between the ages of forty and fifty years, though cases had been observed in children. Dr. Adsit reported six cases operated upon, five of which recovered.

Auscultation of the Cough.—Dr. A. H. Garvin of Raybrook presented this paper. He said that auscultation of the cough offered the best means of diagnosis and it required no expensive apparatus or special experience. He considered four positions of the cough in the respiratory cycle. (1) The cough at the beginning of the inspiration or at the end of expiration. At this point fleeting râles could be heard especially in the axillary region. (2) The cough during some phase of inspiration. At this position it gave important information in the advanced stages of tuberculosis. (3) The cough at the zenith of inspiration. This was not to be used as it obscured the signs. (4) The cough in this position, corresponding to the second position, was during some phase of expiration and frequently revealed abundant râles.

Exactness in the Diagnosis of Renal Calculus.—Dr. Paul M. Pilcher of Brooklyn read this paper. He reviewed the means of diagnosis at their disposal, all of which were useful, and warned against the dangers of manipulative procedures. They were forced to depend on the *x*-ray for size and number of calculi and extent of renal destruction. He considered the different varieties of stones, their different locations and the operations best suited to each.

Dr. Nathan Jacobson of Syracuse exhibited ten *x*-ray plates showing the size and location of various stones; two of them illustrated how shadows might be misinterpreted. He emphasized the necessity of having the intestinal tract thoroughly cleaned out before taking pictures.

Dr. Tinker said that Dr. Pilcher had omitted to mention that the waxtipped catheter was useful in determining the location and character of the stone. In operating on the kidney they should remember that one kidney was absent oftener than was generally supposed. The determination of the freezing point of the urine and blood gave a line on the functional condition of the kidneys.

Exophthalmos a Common Symptom of Bright's Disease.—Dr. H. C. Gordinier of Troy read this paper, which he presented for the purpose of emphasizing the fact that exophthalmos, in varying degree, was a common sign of chronic nephritis occurring in nearly one-half the cases. This symptom was usually associated with hypertension, without enlargement of the thyroid gland or marked tachycardia. It had been entirely overlooked in textbooks and only within a few years mentioned in the medical literature.

Dr. L. F. Bishop called attention to the fact that the degree of exophthalmos in Bright's disease varied with the condition of the patient, being more marked when the condition of the patient became worse.

The Precancerous Stage.—Dr. Parker Syms of New York said it was now generally recognized that certain lesions and conditions led to cancer, such as benign tumors, chronic ulceration, chronic inflammation, scars, pigmented moles, etc. He urged the importance of recognizing these precursors of cancer and said that their early and proper removal constituted the prevention of cancer in the precancerous stage. He especially urged the removal of all breast tumors as soon as discovered, and believed that chronic inflammation of an enlarged prostate might be a precursor of cancer and should be removed in abnormally enlarged glands. He also urged the necessity of curing all gastric ulcers that could be cured and of removing gallstones, which, because of irritation, might be cancer precursors.

Cancer Immunity in Its Present Status.—Dr. Harvey Gaylord of Buffalo stated that a small percentage of primary cancers in animals recovered and that this was true in a few instances in human beings. This had led to their work on immunity. A certain immunity seemed to be conferred by inoculating an animal with a growth from a different species. In regard to this immunity they had found that it was not directed against the cancer cell but against growth; it was entirely independent of the cancer cell. From spindle-celled sarcoma of a rat it had been possible to filter an agent which would produce tumors. They had thus produced one tumor but it was not spindle-celled sarcoma but chondrosarcoma. They thought they had produced sarcoma in two animals by the injection of warm fluid from a cancer of the omentum in a human being. The immunity obtained was specific. The question of vaccination had again arisen and six cases were reported at the late convention in Paris as cured by this method. In all probability the field for the employment of vaccination would be very limited; early cases might be amenable. When tumors began to retrograde it was necessary to remove as much of them as was possible. Rats with small tumors had shown a pseudo-Wassermann reaction or deviation of complement reaction. Three or four normal cases did not develop the Wassermann reaction. The cases that showed improvement gave in course of time a Wassermann reaction equal to a marked syphilitic reaction. This reaction was a mark of growing immunity. A blood reaction known as the antitryptic reaction gave good indications of the progress of the case and enabled one to tell when metastases were occurring. It was not a diagnostic reaction.

Dr. F. R. Ford of Utica said he had observed clinical results where both vaccines from animals and autogenous vaccines had been used. He related a case of cancer of the breast in which vaccines had seemed to effect a cure.

Treatment of Intestinal Tuberculosis.—Dr. Samuel Goodwin Gant of New York classified into intestinal tuberculosis (1) enteric (superficial ulcerative) type; (2) enteroperitoneal (deep ulcerative) type; (3) hyperplastic (tumor forming) type; (4) fibrosclerotic type; (5) peritoneal type and (6) glandular type. In discussing the treatment the writer stated that the results were much better from modern than the older methods and pointed out that more favorable results were obtained in the enteric, where the infection involved the superficial mucosa, than in the enteroperitoneal form, where the inner and outer coats of the bowel sooner or later become involved and that a large proportion of cures were now being effected by improved surgical technique and with comparatively little danger to the patient. He then grouped therapeutic measures employed in the treatment of intestinal tuberculosis into (1) measures for improving the general health; (2) symptomatic treatment; (3) irrigations of ichthyol, balsam of Peru, boric acid or krameria and soda ½ per cent., alternated daily with high injections of olive oil and bismuth to soothe the bowel; (4) topical applications of silver nitrate, 8 per cent. balsam of Peru or ich-

thyol 20 per cent.: (5) surgical treatment, including appendicostomy and cecostomy. He called attention to the value of cecostomy which, with the enterocolonic irrigator, provided a certain means of irrigating both the large and small intestine separately or together.

Chronic Appendicitis: A Critical Study of Post-Operative End-Results.—Dr. E. MacD. Stanton of Schenectady said that chronic appendicitis was a disease ideally suited for surgical treatment, but that the end results in cases operated upon for supposed chronic appendicitis had not thus far been altogether satisfactory was attested by the fact that in almost every community there were more or less numerous patients who had had their appendices removed with no improvement in their symptoms. Better end results must come largely through careful study of the successes and failures of the past, and the investigation upon which this paper was based was undertaken with the idea that the knowledge so gained might enable us to eliminate a certain proportion of the unsatisfactory late results. The majority of patients suffering from chronic appendicitis gave a history of having had one or more attacks of acute abdominal illness generally diagnosed as acute indigestion, but with a sequence of symptoms recognizable as those of an acute appendix attack. In his experience appendical dyspepsia was characterized by symptoms strikingly analogous to the earliest symptoms of acute appendicitis, namely, attacks of epigastric or mid-abdominal pain or distress, but only rarely accompanied by subjective symptoms referable to the region of the appendix. During those attacks the pain or distress was nearly always increased by food intake. Pain confined chiefly to the right lower quadrant and not associated with attacks of epigastric pain and nausea was seldom due to the appendix, and before making a diagnosis of chronic appendicitis in these cases every other possible condition should be excluded. The majority of failures had been in patients complaining of right inguinal pain associated with chronic constipation. These patients had an unusually long or dilated cecum, with enteroptosis.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Indiana State Board of Medical Examiners.

July, 1909.

ANATOMY.

1. Describe the kidneys, giving location, size, form, relation to each other and relation to peritoneum.
2. Describe the colon, giving its location, form, situation, divisions and names, and location of flexures.
3. Give the names of the plexuses derived from the solar plexus.
4. If a fracture occurs at the juncture of the middle and lower thirds of the radius, with the line of fracture extending from above downward and forward, what muscles would displace the fragments, and in what directions?
5. Make a drawing of the plantar surface of the foot, showing the location of the arteries.
6. Describe the duodenum, giving location, its divisions and important relations.
7. Give the cranial sutures and their locations.
8. Make a drawing showing transverse section of the spinal cord, roots of spinal nerve and spinal nerve trunk, with its posterior and anterior divisions, and its relation to the sympathetic nerve cord.
9. Describe the heart, giving location, position, size, general divisions, valves and vessels.
10. Describe the wrist-joint, naming all the bones that enter into its formation.

PHYSIOLOGY.

1. Give the functions of the lymphatic glands and vessels.
2. Describe the pulmonary circulation of the blood.
3. Give the functions of each of the elements of the blood.
4. Define excretion and secretion.
5. How and by what agencies is arterial tension maintained?
6. Explain the physiological processes in the digestion of milk.
7. Name the secretory and excretory organs in parallel columns.

CHEMISTRY.

1. What would occur if sulphuric acid was added to sodium chloride?
2. Give four tests for albumin.
3. Give chemical composition of the blood.
4. Name the enzymes of the body.
5. What is ozone? Give molecular weight, and how does it differ from oxygen?

MATERIA MEDICA AND THERAPEUTICS.

1. Give the different methods of administering drugs.
2. Define therapeutic incompatibility: chemical incompatibility.
3. How is nitrite of amyl administered and for what purpose?
4. Describe the therapeutic uses of sodium chloride.
5. What remedies are employed to correct anemic conditions and how are they used?
6. Mention four preparations of digitalis with the dose of each for an adult.
7. State the name and dose of a drug belonging to each of the following classes: (*a*) emetics: (*b*) diuretics, (*c*) diaphoretics, (*d*) cathartics.
8. What do you understand by specific medication?
9. Give therapeutic action of belladonna.
10. Give therapeutic action of opium.

PHYSICAL DIAGNOSIS.

1. Give distinctions between organic and functional heart murmurs.
2. Give causes and differential diagnosis of cardiac hypertrophy.
3. Give physical signs of aortic regurgitation.
4. (*a*) Define the Cheyne-Stokes breathing. (*b*) Of what disease is it characteristic?
5. Diagnose the following case: "Patient, generally a man past 40, has sudden attacks of vertigo, with tinnitus or incomplete deafness in one or both ears."

PATHOLOGY AND BACTERIOLOGY.

1. Describe an abscess and give its pathogenesis.
2. What do you understand by (*a*) absolute immunity, (*b*) relative immunity, (*c*) acquired immunity?
3. Mention the forms of muscular atrophy, and state upon what each depends.
4. Give the pathology of dysentery: (*a*) catarrhal, (*b*) ulcerative, (*c*) diphtheritic.
5. What do you understand by (*c*) infarction, (*b*) thrombosis?
6. Through what medium is the typhoid infection most commonly conveyed from one person to another?
7. Describe the gonococcus and give the technique of the examination for it.
8. Tell how to differentiate the typhoid from the common colon bacillus.
9. Explain why pathogenic bacteria often prove harmless when taken into the alimentary canal, also why they may not produce disease even when they find their way into the blood current.
10. Name the three general morphological groups of the lower forms of bacteria.

INTERNAL MEDICINE.

1. What conditions predispose to cerebral hemorrhage?
2. What is dysphagia, and with what pathological conditions is it associated?
3. Mention and describe, in regard to the feces, abnormal conditions that are of diagnostic value.
4. State your treatment, including diet, of typhoid fever.
5. Differentiate gastric cancer from gastric ulcer.
6. Give etiology, symptoms, and treatment of acute nephritis.
7. Give etiology, symptoms, and treatment of acute endocarditis.
8. Give diagnosis and treatment of lobar pneumonia.
9. Give symptoms and treatment of tuberculous peritonitis.
10. What is uremia and how should it be treated?

OBSTETRICS.

1. Placenta, give (*a*) function, (*b*) usual location within uterine cavity.
2. Liquor amnii, give (*a*) function, (*b*) composition.

3. Concealed uterine hemorrhage, state cause and give treatment.
4. Early pregnancy, give symptoms (*a*) presumptive, (*b*) positive.
5. Fetal head, in case of failure to engage, what treatment should be employed?
6. Fetal death *in utero*, give (*a*) cause, (*b*) positive sign, (*c*) treatment, and when should it be employed?
7. Prolapsus of cord, state cause and give treatment.
8. Give technique for asepsis in a case of accouchement.
9. If a woman more than seven months pregnant should die suddenly, what effort, if any, should be made to deliver the child?
10. State changes, if any, that take place in the heart of a pregnant female.

GYNECOLOGY.

1. Give general technique of gynecological examinations.
2. Give causes and treatment of inflammation of the vulvovaginal glands.
3. Give diagnosis and treatment of purulent salpingitis.
4. Give differential diagnosis whereby you distinguish ovarian cysts from pregnancy.
5. Give treatment of chronic vesicovaginal fistula.
6. Give technique of operation necessary in lateral tears involving the vaginal sulci.

SURGERY.

1. What is (*a*) sanious pus, (*b*) curdy pus, (*c*) ichorous pus, (*d*) mucopus, (*e*) seropus, (*f*) blue pus, (*g*) red pus?
2. What are the signs of death of a limited part of the body?
3. Give (*a*) etiology, (*b*) treatment of decubitus.
4. Give symptoms of acute tenosynovitis.
5. Give symptoms of fracture of the pelvis.
6. Give treatment of empyema of the chest.
7. Give treatment of appendical abscess.
8. Give technique of sterilization of the hands.
9. Give treatment of external hemorrhoids.
10. Give treatment of cold abscess.

PEDIATRICS.

1. Bronchopneumonia, acute, give cause, diagnosis, and treatment.
2. Thrush, give diagnosis and treatment.

NEUROLOGY.

1. Give five characteristic symptoms of tabes dorsalis.
2. What is tetany?
3. Differentiate between upper and lower neurone disease.

MEDICAL JURISPRUDENCE.

1. Define (*a*) syncope, (*b*) collapse, (*c*) shock.
2. When is it legally permitted to produce an abortion?

LARYNGOLOGY AND RHINOLOGY.

1. Give treatment of antral empyema.
2. Give technique of tonsillectomy.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

INDIANA STATE BOARD OF MEDICAL EXAMINERS.

July, 1909.

ANATOMY.

1. See Cunningham's "Anatomy" (1909), page 1130; or Gray's "Anatomy" (1908), page 1419.
2. The colon is divided into ascending, transverse descending, iliac, and pelvic. The *ascending colon* extends from the cecum to the under surface of the liver to the right of the gall-bladder, where it turns to the left, forming the *hepatic flexure*. It lies in the right iliac and right hypochrondriac regions. The peritoneum covers the anterior and lateral surfaces. Length, 8 inches. The *transverse colon* passes from right to left, from the gall-bladder to the spleen. It forms an arch, convex anteriorly and below: the *transverse arch of the colon*. It is entirely surrounded by peritoneum, which is attached posteriorly to the spine, forming the mesocolon. Length, 20 inches. The *descending colon* passes from the end of the transverse colon by a bend, *the splenic flexure*. Between the splenic flexure and the diaphragm, opposite the tenth left rib, is a fold of the peritoneum, the *costocolic ligament*, which slings up the spleen. The gut then passes downward to the iliac crest, ending in the iliac colon. The peritoneum invests its anterior and lateral surfaces. Length, 4 to 6 inches. The *iliac colon* is continuous with the descending colon at the left iliac crest, and ends at the inner border of the left psoas. Peritoneum invests its anterior and lateral surfaces; it has no mesentery. Length, 5 to 6 inches. The *pelvic colon* extends from the inner border of the psoas to the level of the third sacral vertebra. Length, 16 or 17 inches; very variable. It has an extensive mesentery.—(From *Aids to Anatomy*.)
3. From the solar plexus are derived: Phrenic plexus, suprarenal plexus, renal plexus, spermatic plexus, celiac plexus (with gastric, hepatic, and splenic plexuses), superior mesenteric plexus, and aortic plexus.
4. In fractures of the radius at the juncture of the middle and lower thirds the upper fragment is drawn upward by the biceps and inward by the pronator radii teres; the lower fragment is drawn downward and inward by the pronator quadratus; the supinator longus also depresses the upper end of the lower fragment towards the ulna.
5. See Cunningham's "Anatomy" (1909), page 866; or Gray's "Anatomy" (1908), page 718.
6. See Cunningham's "Anatomy" (1909), page 1065; or Gray's "Anatomy" (1908), page 1290.
7. See Gray's "Anatomy" (1908), page 127.
8. See Gray's "Anatomy" (1908), page 840.
9. See Cunningham's "Anatomy" (1909), page 783; or Gray's "Anatomy" (1908), page 564.
10. See Cunningham's "Anatomy" (1909), page 2831; or Gray's "Anatomy" (1908), page 319.

PHYSIOLOGY.

1. The *functions of the lymphatic glands and vessels* are: "(1) Mechanical, protective, or regulatory of the circulation, the serous surfaces, bursæ, tendon sheaths, the cerebrospinal fluid. (2) The absorption of digested products, the intestinal lymphatics or lacteals. (3) The formation of the blood in the thymus, bone marrow, spleen, and lymphatic glands. (4) The destruction of injurious materials in the spleen, lymphatic glands, and the lymphadenoid tissue of the respiratory tract, especially the nasopharyngeal section."—(Spencer and Gask's *Surgery*.)
2. See Cunningham's "Anatomy" (1909), page 091; or Gray's "Anatomy" (1908), page 1404.
3. The *red blood cells* carry oxygen from the lungs to the tissues. The *white blood cells:* (1) Serve as a protection to the body from the incursions of pathogenic microorganisms; (2) take some part in the process of the coagulation of the blood; (3) aid in the absorption of fats and peptones from the intestine, and (4) help to maintain the proper proteid content of the blood plasma. The function of the *platelets* is not determined; it is possible that they take some part in the coagulation of the blood. The *plasm* conveys nutriment to the tissues; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.
4. *Secretion* is the process by which certain organs (glands and membranes) separate from the blood certain constituents which are further elaborated and serve some further office in the economy.
Excretion is a similar process by which there are removed from the blood waste materials, and products of no further use to the body, and which if retained would be injurious.
5. *Arterial tension:*

MAY BE RAISED BY:	MAY BE LOWERED BY:
1. By the heart beating more quickly.	1. By the heart beating more slowly.
2. By the heart beating more powerfully.	2. By the heart beating more feebly.
3. By contraction of the arterioles.	3. By dilatation of the arterioles.
	4. By deficient supply of blood to the left ventricle.

6. In the *mouth* milk is not altered. In the *stomach* it is precipitated by the rennin; the hydrochloric acid also coagulates milk; the pepsin then dissolves the proteid part into proteoses and peptones. In the *small intestine* the fat is emulsified, the proteid is further converted into proteoses and peptones by the trypsin of the pancreatic juice.
7. (*a*) *Structures of excretion:* Lungs, kidneys, intestines, skin. (*b*) *Structures of secretion:* Serous and synovial membranes; mucous membranes (glands in mouth, stomach, and intestines); salivary glands and pancreas;

liver; mammary glands; lacrymal glands; kidneys; skin; testes.

CHEMISTRY.

1. If sulphuric acid is added to sodium chloride, hydrochloric acid and sodium sulphate result:

$$2\,NaCl + H_2SO_4 = 2\,HCl + Na_2SO_4$$

2. *Four tests for albumins:* (1) They coagulate when heated. (2) When treated with concentrated HNO_3 they become yellow, and change to orange color on the addition of NH_4OH. (3) They become of a purple-red color when warmed to 158° F. with Millon's reagent. (4) Certain metallic salts (solutions of cupric sulphate, mercuric chloride, lead acetate, silver nitrate) will cause coagulation.

3. CHEMICAL COMPOSITION OF THE BLOOD. *Plasma:* Water and solids; the latter containing proteids, extractives, fats, and salts of sodium, potassium, and calcium. *Corpuscles:* Water and solids; the latter containing hemoglobin, globulin, lecithin, cholesterin, iron, and salts of sodium, potassium, magnesium, and calcium.

4. *Enzymes of the body:* Ptyalin, pepsin, trypsin, amylopsin, steapsin, maltase, invertase, lactase, fibrin ferment, rennin.

5. *Ozone* is oxygen in a peculiar state of condensation, the molecule of oxygen contains two atoms, while that of ozone contains three, $3O_2 = 2O_3$. The molecular weight is 48. Ozone is a dark blue liquid; oxygen is a colorless gas.

MATERIA MEDICA AND THERAPEUTICS.

1. *Medicine can be administered:* (1) By the mouth; (2) by the rectum; (3) by inhalation; (4) by inunction; (5) hypodermically; (6) by intravenous injection; (7) by fumigation; (8) by cataphoresis.

2. By *incompatibility* is understood the simultaneous administration or combination of substances not suitable for such combination. *Therapeutic incompatibility* occurs when two agents are administered together which have antagonistic physiological actions, such as morphine and atrophine; this is often intentional. *Chemical incompatibility* occurs when remedies which are mixed together undergo chemical decomposition or explosion.

3. *Nitrite of amyl* is administered by inhalation; in angina pectoris, high arterial tension, cardiac dyspnea, and epilepsy.

4. *Therapeutic uses of sodium chloride:* "Locally, it is of service in affections of the mucous membranes, and salt baths are invigorating as well as cleansing. A strong solution constitutes one of the best injections for threadworms, and salt solutions are also used to limit the action of silver nitrate. Hot salt, enclosed in bags, is a good application in lumbago and various other painful conditions. Internally, as an emetic and also in dyspeptic conditions, administered in carbon dioxide water or in the form of natural mineral waters. Solutions of salt in distilled water are given by intravenous injection or hypodermatoclysis in conditions where the body has lost much fluid, and also in carbon dioxide or coal-gas poisoning and in uremia and similar intoxications. In poisoning by silver nitrate sodium chloride arrests the corrosive action."—(Wilcox's *Materia Medica.*)

5. Iron, arsenic, nux vomica, hypophosphites, and manganese; diet and hygiene. See French's "Practice of Medicine" (1910), pages 520 and 523; or Osler's "Practice of Medicine" (1909), page 730.

6. Extract of digitalis, gr. 1/5; fluidextract of digitalis, ♏j; infusion of digitalis, ʒij; and tincture of digitalis, ♏xv.

7. (*a*) *Emetic:* Apomorphine hydrochloride, gr. 1/10 (hypodermically). (*b*) *Diuretic:* Sparteine sulphate, gr. ij. (*c*) *Diaphoretic:* Solution of ammonium acetate, ʒiv. (*d*) *Cathartic:* Calomel, gr. iv.

8. *Specific medication* means treatment that implies that certain diseases have certain definite remedies which are antidotal. Thus quinine is specific for malaria; antitoxin for diphtheria; mercury and the iodides for syphilis.

9. BELLADONNA. *Physiological action:* Anodyne, mydriatic, inhibits secretions, depressant of terminations of nerves, accelerates the heart beat, causes rise in blood pressure, but toxic doses cause the blood pressure to fall, stimulates the respiratory center, but large doses depress the same; it may cause vertigo, restlessness, excitement, delirium, or mania.

Therapeutic indications: To relieve pain, relax spasm, check sweating, as a mydriatic for night sweats, to check griping of purgatives; in asthma, to check fevers, in heart disease, shock and collapse, acute coryza, urinary incontinence, chordee, low delirium of fevers, mania, alcoholism; as an antigalactagogue, spasmodic cough.

10. OPIUM. *Physiological action:* It is analgesic, hypnotic, diaphoretic, narcotic, a respiratory and cardiac stimulant (later a depressant), it checks most secretions (not perspiration), it stimulates the brain, and contracts the pupil.

Therapeutic uses: As an anodyne, a hemostatic, in inflammations, as an expectorant, in diarrhea, in alcoholism, manias and diabetes, as an antispasmodic, in insomnia, and as a diaphoretic.

PHYSICAL DIAGNOSIS.

1. *Organic murmurs* are due to stenosis or incompetency of one or more of the valves of the heart.

Functional murmurs are not due to valvular disease.

Organic murmurs may be systolic or diastolic; may be accompanied by marked dilatation or hypertrophy, and there will probably be a history of rheumatism or of some other disease capable of producing endocarditis. Whereas a murmur, usually systolic, soft, and blowing, heard best over the pulmonic area, associated with evidences of chlorosis or anemia, and affected by the position of the patient, is a *hemic* or *functional* murmur, and denotes as a rule an impoverished condition of the blood.

2. See French's "Practice of Medicine" (1910), pages 613 and 614; or Osler's "Practice of Medicine" (1909), pages 822 and 827.

3. See French's "Practice of Medicine" (1910), page 600; or Osler's "Practice of Medicine" (1909), page 800.

4. In *Cheyne-Stokes respiration* the respirations gradually increase in volume and rapidity until they reach a climax, when they gradually subside, and finally cease for from ten to forty seconds, when the same cycle begins again. "In the majority of instances it is associated with apoplexy (toward the end), chronic nephritis (uremia), tumor of the brain, tuberculous meningitis, or degeneration of the heart muscle. Less frequently it is observed as a result of cardiac valvular defects and consequent embolism, diabetes, and certain acute diseases, notably typhoid, pneumonia, pertussis, cerebrospinal fever, scarlet fever, and septicemic conditions."—(Butler's *Diagnostics of Internal Medicine.*)

5. Possibly Ménière's disease; but in practice it would be exceedingly unwise to make any diagnosis on such very meager data.

PATHOLOGY AND BACTERIOLOGY.

1. See Rose and Carless' "Surgery" (1908), page 63; or Da Costa's "Surgery" (1908), page 132.

2. See French's "Practice of Medicine" (1910), page 60.

3. MUSCULAR ATROPHY. "*Simple atrophy* occurs as a senile change and from disuse. *Neuropathic atrophy* occurs when a muscle is separated from its trophic center (the nerve cells of the anterior horns of the spinal gray matter), and follows section or inflammation of a mixed nerve, or anterior poliomyelitis; it is most typically seen in the latter in infantile paralysis. *Progressive muscular atrophy* may be of the same nature, but chronic in course, though it is considered by some to be a primary disease of the muscles, with secondary degeneration of the spinal nerve cells. In the juvenile forms and in the pseudohypertrophic paralysis the atrophy seems to be a primary one of the muscles."—(Hewlett's *Pathology.*)

4. See French's "Practice of Medicine" (1910), pages 251 and 254; or Osler's "Practice of Medicine" (1909), page 244.

5. By *Infarction* is meant the plugging of a terminal artery generally by an embolus or thrombus. By *Thrombosis* is understood the coagulation of blood within the heart or blood-vessels during life.

6. "Food, fingers, and flies."

7. The *Gonococcus* is a diplococcus with a special predilection for the mucous membrane of the urethra and vagina. It is sometimes found on the conjunctiva. The appearance is that of two coffee beans; the gonococcus is found in the pus cells, stains with ordinary anilin dyes, but not by Gram's method. It is aërobic, and can be cultivated on human blood serum; it will not grow on gelatin, agar, bouillon, or potato. It was discovered by Neisser.

4. To demonstrate *gonococci:* On a cover-glass make a smear with the discharge as thin as possible, and let it dry in the air; cover it with a freshly made solution of anilin-oil-gentian-violet for one or two minutes; wash it in distilled water; leave it in Gram's solution for two minutes; wash it in 95 per cent. alcohol until decolorized; wash it in distilled water; counterstain with a dilute carbolfuchsin without heat, or with a saturated aqueous solution of Bismarck brown; wash in distilled water, dry with filter paper, mount, and examine with an oil-immersion lens. The gonococci will appear as *diplococci within the leucocytes*, which have been *decolorized by Gram's stain*, and have taken the counterstain.

8. *To distinguish the typhoid bacillus from the colon bacillus:* (1) On gelatin plates the colonies of typhoid develop more slowly than those of colon bacillus. (2) The colon bacillus causes fermentation with production of gas in media which contains sugar; the typhoid bacillus does not. (3) The colon bacillus produces a strong acid reaction and coagulates milk within twenty-four to forty-eight hours; the typhoid bacillus does not coagulate milk. (4) In peptone solution the colon bacillus produces indol; the typhoid bacillus does not. (5) The typhoid bacillus gives the Widal reaction with typhoid serum; the colon bacillus does not.

9. See French's "Practice of Medicine" (1910), page 53.

10. The three basic forms of bacteria are: (1) The *coccus,* which is round or oval, and may appear singly, in pairs, in groups of four, in chains, or in bunches. (2) The *bacillus,* which is rod shaped, with the longer sides parallel and the short ends either straight, rounded, or concave. (3) The *spirillum,* which is spiral.

INTERNAL MEDICINE.

1. See French's "Practice of Medicine" (1910), page 1107; or Osler's "Practice of Medicine" (1909), page 900.

2. See Rose and Carless' "Surgery" (1908), page 879.

3. The feces may be examined *microscopically* for: The *Ameba coli* in dysentery; the *Spirillum* of cholera; the *Bacillus typhosus* in typhoid fever; the *Tænia solium;* the *Oxyuris vermicularis,* and other parasites and bacteria. *Chemical* examination might show the presence of mucin, blood, albumin, peptones, and bile pigment. *Spectroscopic* examination might possibly show the presence of blood. And see French's "Practice of Medicine" (1910), page 1228.

4. See French's "Practice of Medicine" (1910), page 109; or Osler's "Practice of Medicine" (1909), page 99.

5. *Gastric ulcer* is generally caused by injury or bacteria, is most apt to occur between the ages of twenty and forty-five; after eating there is pain localized in the stomach, vomiting occurs soon after eating, hematemesis is common, there is localized tenderness over the stomach, and examination of the gastric contents shows an excess of free HCl; there is no epigastric tumor, though the stomach walls may be somewhat thickened

Cancer of stomach does not usually occur before forty years of age, is more common in males, the pain is localized and constant, vomiting is copious and occurs some time after eating; the vomitus contains "coffee ground" material; hemorrhages are common; a tumor may be palpated, and examination of the gastric contents shows absence of free HCl and presence of lactic acid; there is progressive emaciation; severe anemia and cachexia are also present.

6. See French's "Practice of Medicine" (1910), page 910; or Osler's "Practice of Medicine" (1909), page 686.

7. See French's "Practice of Medicine" (1910), page 577; or Osler's "Practice of Medicine" (1909), page 785.

8. See French's "Practice of Medicine" (1910), page 171; or Osler's "Practice of Medicine" (1909), page 188.

9. See French's "Practice of Medicine" (1910), pages 357 and 408; or Osler's "Practice of Medicine" (1909), page 310.

10. See French's "Practice of Medicine" (1910), pages 905 and 909; or Osler's "Practice of Medicine" (1909), pages 683 and 702.

OBSTETRICS.

1. Placenta. *Functions:* (1) To supply nourishment to the fetus; (2) to act as a respiratory organ for the fetus; (3) to act as an excretory organ for the fetus. Its *usual location* is on the anterior or posterior wall of the uterus, near the fundus.

2. Liquor amnii. *Functions:* (*a*) *During pregnancy:* (1) As a protection to the fetus against pressure and shocks from without. (2) As a protection to the uterus from excessive fetal movements. (3) It distends the uterus, and thus allows for the growth and movements of the fetus. (4) It receives the excretions of the fetus. (5) It surrounds the fetus with a medium of equable temperature, and serves to prevent loss of heat. (6) It prevents the formation of adhesions between the fetus and the walls of the amniotic sac. (7) It has been supposed, by some, to afford some slight nutrition to the fetus. (*b*) *During labor:* It acts as a fluid wedge, and dilates the os uteri and the cervix; it also slightly lubricates the parts.

Composition: Chiefly water, but it contains also small amounts of albumin, epithelial cells, urea, phosphates, chlorides, etc.

3. See Williams' "Obstetrics" (1909), pages 807 and 808.

4. *Positive signs of pregnancy:* (1) Hearing the fetal heart sound; (2) active movements of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpation, and (5) the umbilical or funic souffle.

Doubtful signs of pregnancy: (1) Progressive enlargement of the uterus; (2) Hegar's sign; (3) Braxton Hick's sign; (4) uterine murmur; (5) cessation of menstruation; (6) changes in the breasts; (7) discoloration of the vagina and cervix; (8) pigmentation and striæ; (9) morning sickness.

And see Williams' "Obstetrics" (1909), page 190; or Hirst's "Obstetrics" (1909), page 204.

5. Empty the bladder and rectum; determine if there is a faulty presentation, as bregma, brow, or face. Measure diagonal conjugate and height of symphysis and determine the true conjugate. If this latter measures less than 2¾ inches in a simple flat pelvis, or 3 inches in generally contracted pelvis, the contraction is absolute, and only cesarean section or craniotomy is possible. Ascertain by palpation whether there is serious disproportion between head and pelvis. Malpresentations must be corrected with one hand in vagina pressing upward on the fetal anterior portion of the presenting part, and if possible drawing down in the occipital pole, aided by external manipulation. Press the head downward into the pelvis; this maneuver may be aided by Walcher's position. If there is marked disproportion, cesarean section and craniotomy must be considered. If disproportion is apparently not insuperable, rupture the membranes just after the acme of a pain, when the cervix is fully dilated, keeping the patient in Walcher's position. If the head thereupon engages during the next few pains, allow spontaneous delivery, or aid with forceps if necessary. If the head still refuses to engage, apply axis-traction forceps in Walcher's position, tentatively; if unsuccessful, perform podalic version by combined or internal method. If membranes have already ruptured, note whether there is marked retraction ring. If not, podalic version is proper, subject to limitation of slight disproportion; but if the uterus has retracted markedly, forceps, and that failing, only cesarean section, symphyseotomy, or craniotomy is admissible.—(From Scott's *State Boord Obstetrics.*)

6. See Hirst's "Obstetrics" (1909), page 171.

7. See Williams' "Obstetrics" (1909), page 842; or Hirst's "Obstetrics" (1909), page 625.

8. See Williams' "Obstetrics" (1909), pages 303, 308, etc.; or Hirst's "Obstetrics" (1909), pages 327, 778, etc.

9. See Williams' "Obstetrics" (1909), page 451; or Hirst's "Obstetrics" (1909), page 856.

10. See Williams' "Obstetrics" (1909), page 172; or Hirst's "Obstetrics" (1909), page 186.

GYNECOLOGY.

1. The patient should be free from corsets and constricting bands; the bladder and rectum should be empty. *External palpation:* The patient should be in the lithotomy position, on a suitable table or bed. The examiner stands on one side, and palpates the lower abdomen to determine any enlargement of the uterus. *Vaginal touch:* The examiner separates the labia with the thumb and finger of one hand; and two fingers of the other hand well lubricated are introduced into the vagina. Pressure is made on the perineum until the posterior fornix is reached, when the palmar surfaces are turned forward and the size, position, and condition of the cervix are determined. Then with the palmar surface of the external hand gentle pressure is made on the abdomen and the two hands are approximated. Thus the size, consistency, and position of the uterus are determined. *Rectal examination:* In virgins and in some cases of extreme retroversion one finger is introduced into the rectum and with the other hand on the abdomen a more satisfactory bi-manual examination can be made. *Instrumental examination:* In the lithotomy position, by the use of a bi-valve, a tubular or Ferguson speculum, the condition of the cervix can be inspected. This is best accomplished in some cases by use of the Sims position and the Sims speculum. At the same time in rare and selected cases by steadying the anterior lip of the cervix with a bullet forceps the uterine sound may be passed to determine the size and position of the uterus.

2. *Inflammation of the vulvovaginal glands. Causes:* Trauma, gonorrhea. *Treatment:* Hot or cold antiseptic applications, rest, salines; if an abscess results, excision or incision and drainage.

3. See Hirst's "Obstetrics" (1909), page 753.

4. *Differential diagnosis. Pregnancy:* The tumor is hard and does not fluctuate, is situated in the median line, and may give fetal heart sounds and movements; the cervix is soft, and the other signs of pregnancy are present. The rate of growth of the tumor, and the general condition of

the patient's health may also help in arriving at a diagnosis.

Ovarian cyst: Absence of the chief signs of pregnancy; there may be the characteristic facies, the tumor is soft, fluctuating, is more to one side, and does not show fetal signs.

5. See Hirst's "Obstetrics" (1909), page 883.

6. See Williams' "Obstetrics" (1909), page 325; or Hirst's "Obstetrics" (1909), pages 867, etc.

SURGERY.

1. See Rose and Carless' "Surgery" (1908), page 69; or Da Costa's "Surgery" (1908), page 130.

Blue pus is due to the presence of the *Bacillus pyocyaneus; red pus* to the *Bacillus prodigiosus.*

2. See Rose and Carless' "Surgery" (1908), pages 98, 101, etc.; or Da Costa's "Surgery" (1908), pages 170 and 174.

2. See French's "Practice of Medicine" (1910), page 724; or Osler's "Practice of Medicine" (1909), page 436.

NEUROLOGY.

1. *Symptoms of tabes dorsalis:* Loss of coordination; characteristic and unsteady gait; tendency to stagger when standing up with feet together and eyes closed; sharp and paroxysmal pain, called *crises;* girdle sensation; loss of knee-jerk and other reflexes; Argyll-Robertson pupil.

2. See French's "Practice of Medicine" (1910), page 1170; or Osler's "Practice of Medicine" (1909), page 1074.

3. See Osler's "Practice of Medicine" (1909), pages 881, etc.

MEDICAL JURISPRUDENCE.

1. *Syncope* is sudden loss of consciousness due to acute anemia of the brain.

Collapse is sudden prostration due to causes not strictly surgical, as in some poisonings.

Shock is sudden prostration due to surgical or traumatic causes.

2. *Abortion is justifiable:* "(1) In pelvic deformity where there is sufficient space for a seven months' child to be delivered without injury. The object is twofold: (*a*) to save the child's life by obviating the necessity for craniotomy; (*b*) to spare the mother the dangers of craniotomy, cesarean section, symphyseotomy, or other operations that might be required if the pregnancy went to full term. (2) In cases where, in previous labors, the head of the child at full term has been prematurely ossified, or unusually large, so that labor has been difficult and dangerous, even though the pelvis were normal. The period of delivery need only be two or three weeks before 'term' in these cases. (3) In cases where the children of previous pregnancies have died *in utero* during the later weeks of gestation from disease (fatty, calcareous, or amyloid degeneration, etc.) of the placenta. (4) In conditions where the continuance of pregnancy seriously endangers the mother's life, such as: excessive vomiting; albuminuria; uremic convulsions, or paralysis; chorea; mania; organic disease of the heart, lungs, liver, blood-vessels, etc., threatening fatal disturbance of the respiration, circulation, and other vital functions; irreducible displacements of uterus; placenta previa with hemorrhage; and in dangerous pressure upon neighboring organs from over-distention of uterus, due to dropsy of amnion, tumors, multiple pregnancy, etc."—(King's *Manual of Obstetrics.*)

PULMONARY SYMPTOMS AS PREMONITORY SIGNS OF VENOUS THROMBOSIS.*

By LEWIS A. CONNER, M.D.,

NEW YORK,

PHYSICIAN TO THE NEW YORK HOSPITAL.

In the consideration of pulmonary embolism as a complication of venous thrombosis, one is apt to think only of those sudden fatalities, fortunately rare, in which a patient convalescent from typhoid fever, pneumonia, or some abdominal operation is seized with a sudden thoracic oppression, air hunger, and collapse, and dies within a few minutes or an hour or two. Such fatal emboli usually result from the separation of a large fragment from a thrombus which has gradually extended upward into such large veins as the femoral or the iliacs, and they therefore usually occur late in the course of the phlebitis.

It is my purpose here to call attention to a type of pulmonary embolism which, in its time of occurrence, clinical course, and prognosis, differs radically from that just referred to, and which, I believe, deserves a much more general recognition than it has hitherto had.

Several recent experiences have convinced me that sudden pulmonary symptoms not infrequently precede by a few days or even longer, the obvious signs of venous thrombosis, and that these are unquestionably to be regarded as manifestations of pulmonary embolism and infarction. The following cases will serve as illustrations:

Case I.—H. P., physician, aged 24 years. Seen by me during the absence of his physician, Dr. S. W. Lambert. Onset, on June 9, 1910, of typhoid fever which ran a moderately severe but uneventful course until the twelfth day of the disease (June 21), when during the evening the patient was awakened by sudden, severe, thoracic oppression and a distressing sense of suffocation. His respirations were very rapid, his face was cyanotic and covered with cold sweat, his pulse was extremely rapid and thready, and his whole appearance indicated an alarming state of collapse. At that time there was neither pain nor cough. His general condition improved during the night and on the following day (June 22) he was much more comfortable, but there was still some cyanosis, dyspnea, and thoracic oppression. The physical examination of the chest was entirely negative.

June 23. "Symptoms subsiding. Examination of lungs negative except for somewhat diminished vesicular breathing and a very few faint crepitations below the angle of the left scapula." In the afternoon he began to have pain in the left side of chest which continued through the night and on the following day (June 24) became very severe. There was still little or no cough. At this time there was distinct dullness over the lower part of the left chest posteriorly, diminished vesicular murmur, and many pleuritic râles. No evidence of phlebitis anywhere.

June 26. Patient began to expectorate mucus mixed with dark blood. Temperature 104°, pulse 132, respiration 42.

June 28. "Expectoration of bloody fluid continues. Cough slight. To-day sharp pain in right chest. Temperature falling."

June 29. "Pain less severe. Still raising mucus and dark blood. To-day for the first time patient notices some soreness in calf of right leg."

June 30. Pain in right groin as well as leg, and tenderness along the course of the femoral vein. During the next few days all the symptoms subsided and the temperature fell to normal. Patient continued however to expectorate from time to time dark bloody fluid.

On July 5 he felt some pain in the left calf and the temperature rose slightly. No further symptoms developed until July 14, when distinct signs of phlebitis in the left femoral vein appeared. These symptoms gradually subsided; the signs of plastic pleurisy in the left chest disappeared, the sputum lost its blood-stained character, and the patient made a slow but complete recovery.

Case II.—L. C., male, No. 20.379. Admitted to New York Hospital September 9, 1910, on the sixth day of illness, marked by headache, fever, weakness, and anorexia. His spleen was enlarged, the blood showed a marked leukopenia, and the Widal reaction soon became positive. His illness ran a moderate and uneventful course and his fever was falling by lysis when on September 21, at 5 P.M., he developed sudden very severe pain on breathing which he referred to the right hypochondrium. There was increased rapidity of breathing (40 per minute); slight increase in the pulse rate (100), rigidity of the upper half of the right rectus muscle, and tenderness on pressure in the right hypochondrium. No other symptoms. At this time examination of the lungs was negative, but three hours later (8 P.M.) many "crackling pleuritic râles" could be heard in the right axilla. The temperature had risen to 102.2° F. and the respirations were still rapid. The leucocytes rose from 3.400 to 9,000 and the polynuclear cells from 62 to 67 per cent. The pain continued through the night but was less on the following day and both the pain and the signs of pleurisy soon disappeared. The records contain no mention of any cough or expectoration. One week later (September 28) patient complained of pain and tenderness in right calf and later showed some edema of the foot and ankle. A few days later the same signs appeared in the left

*Read at a meeting of the Practitioners' Society of New York, March 3, 1911.

leg. No further pulmonary symptoms appeared and patient made a good recovery.

Case III.—Mrs. S., 35 years old, No. 15,687. Admitted to New York Hospital July 30, 1907, on the thirteenth day of illness. She presented all the usual evidences of typhoid fever, which ran a moderately severe course, gradually defervescing so that on the twenty-second day (August 8) the temperature remained below 100° F.

On August 9, at 8 A.M., temperature was 98.6° and patient felt well. At 8.40 A.M. she complained of acute pain in the region of her heart, became cold and blue, and broke out in a cold sweat. Patient had three such severe attacks of pain within an hour. The pulse rose from 72 to 116, the respirations from 20 to 44, and the temperature from normal to 103.6° F. During the afternoon and evening there were frequent paroxysms of pain in the left chest, the patient was cyanosed and cold, the pulse rapid and feeble. There was also distinct rigidity of the upper part of the left rectus muscle, with tenderness.

During August 10 and 11 there was a troublesome dry cough with more or less pain in the left chest, especially upon attempting to lie on the left side. Pleuritic friction sounds could be heard in the left axilla and there was a distinct pleuro-pericardial rub.

August 12. "Patient still somewhat cyanotic. Dry cough and pain in left axilla persist."

August 13. "To-day the cough is accompanied by blood-stained expectoration. Over right base posteriorly, impaired resonance, diminished breathing, and many crepitant râles. Over the lower half of the left chest are many crepitant râles."

August 14. "Sharp pain in right side of neck and shoulder. Troublesome cough but no expectoration."

August 15. "Pain in the front of right chest. Dullness at right base almost gone."

August 17. "Dull ache in left leg. No physical signs."

August 18. "Pain and stiffness in left leg and tenderness in left groin."

August 19. "Stabbing pain in right side of chest."

August 20. "Expectoration of bright blood. This continued for several days."

August 26. "Pain and tenderness in right groin."

No further pulmonary symptoms. During all this time no material change from the original leucopenia. The patient made a good recovery. Discharged cured September 27, 1907.

Case IV.—Mrs. H., aged 60 years. In March, 1906, developed a very severe streptococcus infection of the tonsils with marked constitutional disturbances, delirium, and high, irregular fever. On the fifth day the patient complained of pain in the left side of chest, began to cough and to raise blood-streaked sputum, and presented the physical signs of a very small area of pneumonia just within the lower angle of the left scapula. The signs of consolidation did not increase in extent, and four days later disappeared altogether. The temperature, however, continued irregularly high and the general condition showed little improvement. Three days later (seven days after the appearance of signs of consolidation) the patient complained of pain in the left leg and showed tenderness on pressure over the popliteal vein. A few days later similar signs of phlebitis appeared in the right leg. Eventually the inflammation involved the femoral veins of both legs and many of the small veins of the thighs and buttocks and resulted in a long, tedious illness and slow convalescence.

Time of Occurrence of the Pulmonary Symptoms.—In these four cases the interval between the onset of the pulmonary symptoms and the first indication of phlebitis or thrombosis was respectively 8, 7, 8, and 7 days. In another instance, to be cited later (Case IX), the interval between the onset of the chest symptoms and the frank signs of phlebitis was seventeen days. The explanation for this apparent paradox of the appearance of the signs of pulmonary embolism some days before any thrombosis has developed lies, of course, in the fact that thrombosis has usually begun long before there are any clinical manifestations of phlebitis in such large veins as the femoral or saphenous. In most cases the thrombosis of such a vein as the femoral, with its clinical picture of pain, tenderness, and induration along the course of the vein, and edematous swelling, represents the culmination of the process, not the beginning. In the majority of cases, certainly, the process begins in the small veins, especially in those of the calf, and for a time either gives no symptoms at all or reveals itself only by such vague and indistinct symptoms that their significance is often quite misunderstood. It is apparently from these small veins and from the newly formed friable thrombi that the frequent small pulmonary emboli arise.

Not always, however, do the pulmonary symptoms precede those of the thrombosis. Sometimes they appear about the same time as do the symptoms of phlebitis; sometimes the pulmonary insults occur from time to time throughout the course of the phlebitis.

Case V.—V. P., male, No. 20,284. Admitted to New York Hospital, August 22, 1910, on the tenth day of illness. All the usual symptoms of typhoid fever of moderate severity, followed by normal defervescence. He sat up first on September 16 and took a few steps first on September 18. Convalescence uneventful until September 21, when he complained almost simultaneously of sudden sharp pain in the right side of his chest and pain in the right thigh. Distinct friction sounds could be heard in the right axilla. The temperature, after having been normal for ten days had, the evening before, risen to 100.6° F., had fallen to normal in the morning, and in the evening rose to 103°. Fever continued for four days. Examinations of the painful thigh showed at first "no tenderness, no signs of phlebitis," but on the following day there was tenderness in the lower and outer part of the thigh. The pain in the chest and the signs of pleurisy soon disappeared; the evidences of localized phlebitis gradually subsided and the patient was discharged cured on October 6.

Case VI.—Mrs. L., wife of a physician, was delivered of her first child, after normal labor, and had a satisfactory convalescence up to the eighteenth day. At that time, after having been out of bed for several days, she complained of some pain in her left calf. At the suggestion of the physician in attendance massage was applied to the leg by the nurse and while this was in progress the patient experienced sudden intense thoracic oppression, dyspnea, faintness, and fluttering of the heart. She grew very pale and the pulse became extremely rapid and almost imperceptible. These symptoms soon abated, but within an hour or two she developed sharp pains in the left side of the chest, the

respirations continued rapid, and the temperature rose. There was slight cough. She was seen by me on the following day. The pain in the left chest, rapid breathing, fever, and cough persisted, and posteriorly over the upper part of the left lower lobe a small area of consolidation could readily be made out by physical examination. There were some tenderness and pain in the left calf, but no other evidences of phlebitis. At the end of four days the small patch of consolidation had disappeared and the temperature fell somewhat. On the following day, however, there was sudden pain in the right side of the chest followed by the signs of a small area of pneumonia in the *right* lower lobe which likewise resolved after three or four days. The sputum was at no time bloody or rusty. In the meantime the signs of phlebitis in the left leg had become more pronounced and evidences of similar trouble had appeared in the right leg. The thrombosis eventually involved not only both femoral veins but extended up into the iliacs and was accompanied by great edema not only of the lower extremities but also of the buttocks and lower part of the abdomen. After a very severe and protracted illness the patient finally made a good recovery.

Case VII.—V. A., male, aged 42 years. Admitted to New York Hospital February 8, 1910, on the sixth day of typhoid fever which ran a long and severe course. On February 19 chill at 10 A.M., and later pain and tenderness over left femoral vein. No change in leucocytes. Up to that time patient had had no cough whatever. That night he was disturbed several times by severe coughing attacks which ceased next day. Temperature high. Patient delirious at night.

February 26. Chill. Temperature 105.8°. Signs of phlebitis of right femoral vein.

Patient continued very ill. Delirious much of time. Temperature high.

March 5, 7.30 A.M. Sudden severe pain in right chest, made worse by coughing; 8 A.M., expectorated blood clot and mucus; 3.50 P.M., "some dullness and subcrepitant râles at right base behind"; 10 P.M., "coughing up bright blood."

March 6. "Expectoration of bright blood continues. Still some pain in right chest."

March 7. "Expectoration of dark blood clots and mucus. Troublesome cough."

March 8. "Cough less. Over lower part of right chest posteriorly there is a dullness, diminished breathing with suggestion of bronchial quality, and a few râles."

March 13. "Still some cough with bloody expectoration."

The pulmonary symptoms gradually subsided and patient made a good recovery, although some edema of both legs persisted. No change in the leucocytes.

Frequency of Pulmonary Symptoms in Venous Thrombosis.—I have attempted to get some idea of the frequency of this complication of venous thrombosis by going over the histories of all the cases of typhoid fever treated in the New York Hospital during the past five years in which venous thrombosis has been a complication.

There were twenty-seven such cases. In six of these (22 per cent.) there were thoracic symptoms of such a character as to make it reasonably certain that they represented pulmonary embolism and infarction. These six cases together with three cases seen outside of the hospital form the basis of this paper.

I am inclined to believe that the percentage of cases in which pulmonary embolism complicates venous thrombosis is considerably larger than these figures indicate. In typhoid fever, for example, venous thrombosis often develops at a time when the patient is so ill and is in such a state of apathy or stupor that a small pulmonary embolus would give rise to no distinguishing symptoms.

Symptoms of Pulmonary Embolism and Infarction.—Thoracic pain was the most constant symptom among the cases here recorded. It was present in every case and in most of these it was also the first symptom. In two instances it was noticed only a day or two after the appearance of the other symptoms. It was felt in the side of the chest, in the shoulder, or in one or the other hypochondria.

Sudden thoracic oppression, with air hunger and cyanosis, ushered in the symptoms in two of the cases, and in each was associated with alarming signs of collapse. In several other cases it was present in a less severe form.

Cough was an inconstant symptom. Once it seems to have been absent altogether. In a second case it did not appear until two or three days after the violent onset of the pulmonary symptoms, and then it was slight. In several of the cases it was the first indication of pulmonary trouble.

In five of the nine cases bloody sputum was raised at some time. It is interesting that in three of these the blood first appeared several days after the onset of the pulmonary symptoms. In several instances the discoloration of the sputum lasted for many days. In no case was the sputum typically rusty.

In most cases it was difficult to judge of the influence of the pulmonary insult upon the temperature. In a few instances the temperature rose rapidly about the time of the appearance of the pulmonary symptoms, but this did not always happen, and in most cases it was not possible to say whether the variations in temperature depended upon the phlebitis, the infarction, or the primary disease.

Much the same may be said concerning the behavior of the leucocytes. The surprising thing was that, with the complications of an extensive phlebitis and various pulmonary disturbances, the leucocytes should be so slightly changed. In only one case (VIII) was there any considerable increase in the number, and in the polymorphonuclear percentage, of the leucocytes.

Rigidity of the upper portion of the abdominal musculature and tenderness just below the ribs were present in two or three cases in which the infarction was evidently situated at the diaphragmatic surface of the lung.

As regards the physical signs, the cases seemed to fall into three fairly distinct groups: 1. Those in which a few friction sounds or crepitant râles were the only signs. These signs usually lasted only a day or two.

2. Cases in which the signs were those of a small, circumscribed pneumonia. The area of consolidation did not increase or extend, and in each instance the signs of consolidation disappeared within three or four days.

3. Cases with signs of quite extensive plastic pleurisy, as shown by marked dulness; diminution of the respiratory murmur and the vocal fremitus, and many râles. In one case the signs suggested the presence of fluid. In this last group the physical signs persisted for two or three weeks.

Still one symptom remains to be spoken of—that of chills. In the two cases now to be related chills had a conspicuous place in the clinical picture and were at the time as puzzling and inexplicable as the chills of typhoid fever are apt to be. While some of the chills were in all probability due to the exacerbations and extensions of the phlebitis, others of them bore such a distinct relation to the time of the appearance of the abrupt pulmonary symptoms as to make it seem highly probable that they corresponded with and resulted from the lodgment of emboli in the pulmonary vessels.

Case VIII.—J. M., male, No. 14,283. Admitted to New York Hospital August 31, 1906, on the fifteenth day of illness, having had fever, occasional chilly feelings, and weakness. Had enlarged spleen, rose spots, and Widal reaction. Had begun to cough the day before admission. "Lungs normal except for a few scattered râles." Leucocytes, 9,000.

September 2. Chill at 4 P.M., with rise of temperature from 102.4° to 105.6°. At 8 P.M a second chill; temperature, 106.6°; respiration, 36; pulse, 124.

September 3. Chill at 8 A.M., and again at 7 P.M. No cough, pain, or expectoration noted. Leucocytes, 10,000. Polynuclears, 79 per cent.

September 5. 4 P.M., chill.

September 6. Slight resistance and tenderness in left upper quadrant of abdomen. "Complains of pain in left shoulder." "No tenderness or pain on motion." "Lungs clear." 11 P.M., chill, with high temperature. Leucocytes, 17,800; polynuclears, 83 per cent.

September 7. Chill, 7:30 A.M. "Severe pain in left chest, relieved somewhat by strapping chest."

September 8. "Patient has had three attacks of severe pain in left side, each time accompanied by profuse sweating. Many fine crepitations over lower left back and in left axilla, brought out after coughing."

September 9. "Pain in left side less severe. Crepitant râles persist. No dullness."

September 10. Dullness over left back from spine of scapula to base. Diminished vesicular breathing from spine to lower angle of scapula. Below this bronchial expiration and distant voice. Tactile fremitus much diminished.

September 11. Pain gone. Signs of fluid over lower half of left chest, but needle inserted in two places reveals no fluid."

September 12. 6 P.M., chill, with rise of temperature to 106.4°; respiration, 40; pulse, 140.

September 14. Signs in left chest unchanged, except that a few crepitant râles are to be heard. Chill at 6 P.M.

September 17. Temperature now normal. "At left base dulness, diminished fremitus, a few râles, and a soft bronchial breathing. Signs do not extend into Traube's space." Leucocytes, 10,000; polynuclears, 78 per cent.

On September 18, 19, and 20 some elevation of temperature without apparent cause. "Signs in chest diminishing."

September 23. "Temperature rose last night, and to-day there is pain in the left groin and tenderness and induration down the popliteal space." "Legs somewhat swollen." Leucocytes, 26,400; polynuclears, 79 per cent.

September 24. Cough more troublesome. "Is raising bloody sputum to-day." Now some dullness with diminished breathing and voice at right base.

September 25. "Sputum still bloody. Lung signs as yesterday."

From this time on all the symptoms gradually subsided. The chest signs became normal, the cough and bloody sputum ceased, the tenderness and edema of the legs disappeared, and the patient made a slow but complete recovery.

Case IX.—Miss P., No. 13,748. Admitted to New York Hospital, April 6, 1906, on the eigth day of typhoid fever, which ran a very severe and protracted course. There were much nausea and vomiting, great restlessness, insomnia, and nocturnal delirium.

On April 21 the patient first complained of pains in the toes, and for the next three or four weeks suffered much from what was for a time supposed to be a sensory neuritis of the toes. On the same day she began to cough, and developed much soreness and tenderness on pressure in the left calf.

April 23. "A small area of tenderness has appeared in right groin just below Poupart's ligament."

April 25. "Coughing and expectorating a great deal. Over base of right lower lobe are heard coarse moist râles."

April 26. "Still coughing. At 6:20 P. M. slight chill and rise of temperature to 105°. With this, marked change in appearance and general condition. Face cyanosed, extremities cold, respirations rapid, pulse rapid and feeble. Abdomen distended but not rigid." On the following day the general condition had improved somewhat, but patient had two severe chills, each followed by profuse sweating.

During the next few days patient had several more chills, the temperature remained high and irregular and the general condition very poor.

On May 6 there was again pain in the left leg with slight swelling and edema. During the next two weeks the patient's condition improved in spite of a number of hard chills.

May 22. Chill at 3 P. M., followed by very severe coughing and that evening by severe pain and some tenderness just below the left breast. On the following morning friction rubs were audible in the lower part of the left axilla. These symptoms gradually subsided, the chills ceased, no further signs of phlebitis appeared, and the patient eventually made a complete recovery.

There was practically no change in the number and the differential count of the leucocytes.

A case in which the relation of chills to attacks of pulmonary embolism is even more strikingly shown has been reported by Rothe.*

Summary.—The chief points to which attention is called and which, it is believed, are illustrated by the preceding cases are as follows:

Pulmonary symptoms are, not infrequently, the first indication of a beginning venous thrombosis, preceding often by several days the local evidences of such thrombosis. Such symptoms are the result of the lodgment in branches of the pulmonary artery of emboli derived from the newly formed, friable thrombi in the peripheral veins. These early pulmonary emboli are usually of small size and the symptoms arising from them are frequently slight and transient. The symptoms of pulmonary embolism and infarction by no means always correspond to the classical descriptions of them. One or more of the cardinal symptoms are frequently

*Unterleibstyphus mit nachfolgenden Lungen-Infarcten. —*Memorabilien,* XLIII, 1900-1901, page 193.

lacking. This is especially true of hemoptysis, which is often absent entirely, and at other times appears only several days after the onset of the other symptoms. The physical signs are usually either those of a more or less extensive plastic pleurisy or of a small area of pneumonic consolidation which lasts only for three or four days.

Venous phlebitis and thrombosis, in very many instances, begins in the small peripheral veins, especially in those of the calf, where it may exist for some days before the symptoms of thrombosis of the large veins appear. The chances of pulmonary embolism seem to be much greater at the beginning of a venous thrombosis than later on in its course.

Some of the obscure chills in typhoid fever are related to the lodgment of pulmonary emboli.

STREET SANITATION IN NEW YORK.*

WITH SOME SUGGESTIONS FOR ITS IMPROVEMENT.

By WILLIAM VAN VALZAH HAYES, M.D.,

NEW YORK.

"When the public makes up its mind no longer to endure impure milk, impure water, and impure air, and unreasonable dangers to life and limb, life will lengthen eight years, and probably a great deal more." This is Professor Irving Fischer's[1] remarkable statement, and he further maintains that "three-fourths of the tuberculosis from which 150,000 Americans die annually could be avoided."

Already much has been accomplished to secure pure food and pure water. Tenement house laws have been passed with a view to providing for the poor better homes with more light and air. It is the purpose of this article to emphasize the importance of pure air in New York and to point the way to secure for the inhabitants of this great metropolis and other cities air approximating the purity which exists after a hard rain or snowstorm—but little less pure than that of the country.

The air of New York is ordinarily renewed at a rapid rate and, were it not almost immediately contaminated by dust, cinders, and foul gases, would be nearly as pure as when coming across the hills of New Jersey. It is chiefly dust, made up largely of irritating particles of mineral and vegetable matter, filthy ashes, the excrement from animals, and many varieties of bacteria, which may and does convert the life-giving air into a source of danger.

"Of the pathogenic microorganisms which appear constantly in New York dust, we must place the tubercle bacillus as probably the most important; next to it are found all manner of cocci, many varieties of colon bacilli, and the *Bacillus aerogenes capsulatus*." * * * "Less frequent but possibly infecting organisms are the bacilli of tetanus * * * glanders, diphtheria, anthrax, malignant edema, and undoubtedly from time to time the bacilli of typhoid fever and of epidemic dysentery."[2] Dust cannot at present be escaped by the resident of the city, even though he hold his breath when passing through heavy clouds of ashes and dust, veritable "germ showers," or have the unusual wisdom to walk on the eastern side of the street when the wind is in the west. For it apparently is not generally known that when the wind is from the west it strikes against the buildings on the east side of the street, reaching the sidewalk but little contaminated, and then swirls back to the west, carrying with it large amounts of street dust and gas from automobiles. He who would breathe the purest air available in the New York streets must watch the direction of the wind with as much care as a sailor at sea.

Sixteen years ago Dr. T. Mitchell Prudden vividly described the dangers of dust and said: "The number of living germs which the New York citizen is liable to be forced to take into his body, when the streets are dry and the wind blowing, or when the dry filth is being stirred up by the diabolically careless procedures of the present street cleaning fiends, it would be a thankless task to tell." He reported interesting tests made by means of culture plates three and three-quarter inches in diameter, which were exposed for five minutes in different parts of New York. It was found that the number of living germs settling on the plates in the different parts of the city were as follows: (1) Central Park, dust blowing from an adjacent street, 499; (2) Union Square, 214; (3) private house, 34; (4) large retail dry goods store, 199; (5) Broadway and Thirty-fifth street, 941; (6) street in the process of being cleaned by the Street Cleaning Department, 5,810.

While conditions are not quite as bad as they were fifteen or twenty years ago, great improvement is imperatively demanded. Watch one of the modern "white wings" in the center of Sixth avenue, vigorously wielding his brush and raising a cloud of dust, which the breeze carries to the sidewalk, completely enveloping the unoffending pedestrians, and Dr. Prudden's statement[4] will not seem inapplicable to the present day.*

The precise amount of illness directly traceable to the dust it is impossible to calculate. Some of the able men connected with our health department believe that the street dust is probably injurious only because of its irritating effect, producing catarrhal conditions of the mucous membranes which give ready entrance to germs acquired from other sources. But the investigations of the following scientific men make one incline to believe that the dust is directly infectious.

Dr. John Weinzirl,[3] after attenuating tubercle bacilli with normal salt solution, thus making the conditions the more unfavorable to them, exposed the bacilli to diffuse light in a room and reached the following conclusions: "These experiments not only confirm the view that diffuse light acts as a germicidal agent, but they also show that such light possesses a true germicidal effect independently of desiccation. Specifically, they show that *Bacillus tuberculosis* is killed by diffuse light within a week, usually within three or four days, and it may be killed even within a single day."

Baldwin,[4] [5] at the International Congress on Tuberculosis, states that dry bacilli from cultures may lose virulence in three weeks, but the more im-

*In the accompanying plate are shown photographs of the results of four agar-plate exposures in the streets of New York.

Figs. 1 and 2 show plates exposed in Waverley Place, between Fifth Avenue and University Place. First plate under ordinary conditions; it shows 240 colonies of bacteria. Second plate after washing of the street by a squeegee; it shows 85 colonies. (Courtesy of Hon. Wm. H. Edwards.)

Figs. 3 and 4 are from photographs of plates exposed for five minutes at the southeast corner of Thirty-fourth Street and Broadway. Plate 1 exposed at 10 P.M. March 11, 1911, a strong northwest wind blowing; 320 colonies. Plate 2 exposed in the evening of February 16, 1911, a moderate west wind blowing, clear, temperature 45° F., thawing snow, no dust; 77 colonies. Made by Dr. F. E. Sondern.

portant question as to their viability in naturally dried sputum involves such varying conditions that the preservation of infective power depends upon the size and thickness of the sputum, mass, its quality, its place of deposit with reference to the character of the surface, and, most important of all, its exposure to light, heat, and air. When sputum of tenacious character is dried in large masses, the bacilli are shut out from the air in the hard, glue-like crusts; and in a dark, cool place, such as a basement room or the corridor of many city dwellings, the maximum period of vitality may be assumed to be from six to eight months; this is the estimated limit given by Cornet.

After reviewing the work of various authors upon the action of the sunlight on tuberculous sputum, Annett[6 7] states that their results appear to be somewhat at variance. His experiment to determine the effect of the English climate upon the tubercle bacillus was as follows: A quantity of mucopurulent sputum, from a case of pulmonary tuberculosis, which showed a number of tubercle bacilli in every field, was divided into small masses of the size that would be ordinarily expectorated by a person on the street. These were exposed to the action of sunlight for varying periods of two, four, six, twelve, twenty-four, and forty-eight hours, on four days having an average temperature of about 65° F. and a light breeze.

"Twenty-four hours of exposure to sunlight, during eight of which there was direct sunlight, throughout the remainder the sun being slightly clouded, failed to kill the tubercle bacilli, as shown by inoculation into guinea pigs. All the specimens exposed for two to twenty-four hours contained virulent bacilli. Forty-eight hours' similar exposure, however, killed the bacilli."

Dr. William H. Park,[8] writing on the "Transmission of Diphtheria," says: "In actual experiment the bacilli have been observed to remain virulent in bits of dried membrane for twenty weeks. Dried on silk threads Abel reports that diphtheria bacilli may sometimes live 172 days."

The importance of such testimony becomes apparent when one considers the degree to which our streets are shaded by tall buildings, elevated railroads and platforms, and the marvelous efficiency of an army of human feet, wagons, and, most of all, automobiles, in helping the winds convert mud into dust in a few hours. Is there any reason to doubt that dust with tubercle bacilli, diphtheria bacilli, and other germs, still virulent, may be the means of direct infection of the mucous membranes of the eyes, nose, throat, and lungs?

The past few years have recorded marked advances in the cleaning of the interior of our dwellings, as the broom and feather duster have given way to the carpet sweeper, the dust cloth, and the suction cleaner. The gain is manifest, and were it not for the large quantities of dust coming in through the windows, the housekeeper would have a relatively light task. What is now especially needed is to cut off a large portion of this evil at its chief source by removing the street dust.

It is not the intention of the writer to criticise our present capable Street Commissioner, as it is well recognized that he wishes to solve the problem which has so long failed of solution, but rather to help create sentiment that shall supply him with all necessary equipment and sustain him in his efforts to really *clean* the streets.

Notwithstanding the fact that the sum of $7,500,000 is spent annually, and that 6,500 men are regularly at work on our 2,200 miles of streets, the state of the latter is deplorable. This is largely due to gross carelessness and lack of interest on the part of the citizens, but it is partly due to antiquated and insufficient methods of cleaning and the employment of cheap, though not truly economical, means of such removal. What, then, can be done?

In solving the problem of obtaining sanitary streets, two factors must be considered. First:

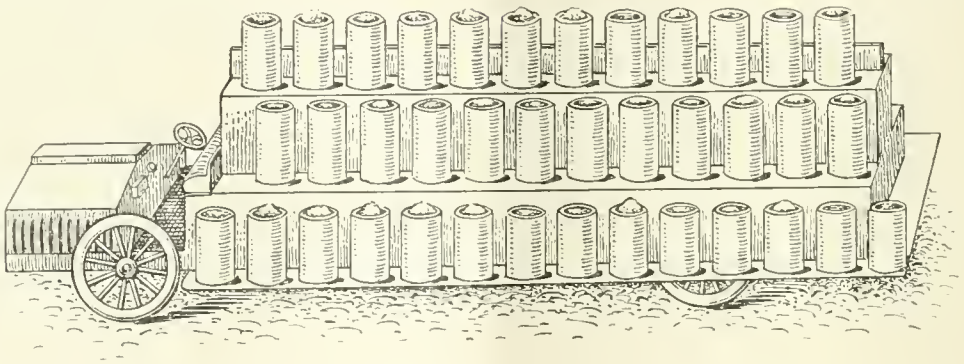

Fig. 1.—Proposed automobile ash and garbage collector.

How to prevent the throwing of material into the streets. Second: How to efficiently remove the unavoidable dirt and fine dust, which is the most dangerous portion of the street refuse. As to the former, a much needed campaign of education already begun must be carried on to train the people to fear the dangers of filthy streets and to enlist their interest in keeping them clean. Although our citizens are accustomed to throw all sorts of trash and garbage into the streets, there is no good reason why such practices should be continued, and when it is made plain to all that by so doing they are not only enormously increasing the burden of expense to the city, but are thereby doing injury to their own health, the present wise sanitary laws will be observed more strictly. Why should New Yorkers be greater offenders in these details than, for instance, the citizens of Berlin? It ought to be possible to stop the shaking of dust cloths and rugs from the windows, the sweeping of dust from the elevated stairs, and the various similar infringements of the rights of others. Just as spitting in our public conveyances has been largely prevented, it is believed that progress can be made in these matters. This sentiment must be fostered, if need be, by a few arrests and suitable fines, as has been successfully done elsewhere.

The present sanitary laws preventing spitting on

DR. HAYES' PAPER.—Cultures on Agar Plates Exposed at Street Level

the sidewalks should be vigorously enforced, and the prohibition extended to the streets, since this is only slightly less dangerous than the former. It must be admitted that a large percentage of our citizens, grown people and children alike, are suffering from catarrh of the throat, nose, and bronchial tubes, largely induced by the very dust from which we are all so eager to escape. Inasmuch as the unhealthy excretions should not be swallowed, it would be unjust to enforce such a law unless suitable provision were made for expectoration.

The methods of removing ashes, it is believed, can be greatly improved, either by using larger carts, or wagons covered by metal or canvas, with trap door openings, or by the city supplying ash cans at cost, or very moderate rental, and using these interchangeably, bringing empty cans as the full ones are removed. It would be possible to carry these in large numbers on long, low wagons or automobiles having tiers of shelves on each side (Fig. 1). Each automobile of this type would start with its load of clean empty cans previously sterilized by steam or dry heat—no objection could then be raised to receiving them—and would return with these cans exchanged for others full of ashes. In this way the emptying of the cans in our streets would be avoided and a great saving in dust formation accomplished. In the writer's opinion a modification of the dustless wagons, such as are used in Charlottenberg, Germany (Fig. 2), would be even more economical and satisfactory.

Fig. 2.—Charlottenburg, near Berlin.—House refuse cart with can of refuse being emptied by mechanical appliance which prevents the escape of dust and odor. (By courtesy of Dr. Geo. A. Soper and The Engineering News.)

A prolific and most annoying source of dirt, indoors and out, is the burning, with incomplete combustion, of soft coal, which results in the staining of beautiful buildings and the soiling of books, stationery, and clothing; all this in addition to the more serious harm of damaging mucous membranes and shortening lives. Although a veritable nuisance, and one which can be done away with by the offenders (smoke consumers and other devices making it practicable), yet it is not likely that much will be done for its abatement until more drastic laws are passed, and a body of inspectors kept at work to see that the regulations are enforced. In this way the offenders in the city, the factories, the hotels, and the apartment houses, could be controlled; but there would still remain the boats in the river and the manufacturing plants on the Jersey shore making their contribution of grimy dirt

It is the belief of the writer that large cities are not suitable places for four-footed animals, and that dogs and cats especially should be completely banished. The environment is unsuitable for them and their presence is fraught with danger. It results in the most disgusting contamination, not only of our sidewalks and streets, but of the grass plots of our small parks, which are to that extent less suitable as playgrounds for the children. People generally do not realize to what extent dogs and cats are subject to communicable diseases. Dogs suffer from many of the diseases that afflict man; skin diseases, tuberculosis, tapeworm, echinococcus infection, etc., and are not to be feared simply because they may have become victims of that rare disease, rabies. The horse is a necessary evil, but a rapidly lessening one, owing to the increasing use of automobiles. As they diminish in number there will be less dirt in the streets, and a marked diminution in the number of flies, 95 per cent. of which, it is said, are bred in horse manure. This latter evil can be controlled in large measure, and will doubtless receive proper attention from the health authorities.

The police should regard it as one of their most important duties to cooperate with the Street Cleaning Department. The hand which interposes an invisible wall before the hurrying traffic on our crowded avenues would be an invaluable aid in enforcing sanitary regulations. It should be the duty of the police to demand an explanation from the occupants of the houses in case newspapers or rubbish are found on the sidewalks or streets. And it is a question if it might not be well to go back to the method of long ago, when each householder cleaned to the center of the street in front of his own house, to this extent, that each owner or lessee of a building or lot be required to keep the area in front of it to the center of the street free from paper, pieces of wood, or similar coarse rubbish.

As has been said, the broom and shovel method of dust removal now in general use is unsatisfactory, resulting (to a considerable degree) in stirring up the dust rather than in taking it away. It is believed that there are but two efficient methods for taking away the dust. The first of these is through flushing, by means of the ordinary horse, or by the use of high pressure flushing machines and brushes or squeegees, as recommended by Commissioner Edwards. This results in carrying the dirt to the gutters and to some extent into the sewers, which have to be protected by proper screening. Even so it is probable that a considerable amount of detritus is washed into the sewers, necessitating costly cleaning operations. And the wetting of the streets makes them slippery and dangerous alike for horses and automobiles, and consumes a large amount of precious drinking water, as the contaminated river water is unsuitable for this purpose.

The second method is by means of automobile suction cleaners. The writer has long advocated the use of these, and is convinced that one of the type represented in the illustration (Fig. 3) would be effective. A large, strong automobile is necessary, with horse power not only for its own propulsion, but to run revolving brushes and fans, or other suction apparatus sufficiently powerful to take up

all the dry matter thrown up by the brushes—dust, dry horse manure, small bits of paper, or similar material that might legitimately collect in the streets. The dust loosened by the brushes is carried by suction into a large bin, to be emptied later on. This method would be available on all the smoothly paved streets during the greater portion of the year. Similar machines are now in successful operation in Berlin, Vienna, and other cities. The initial cost of such equipment would be large, but it is likely that in the end a considerable saving to the city would result. Even if the cost should prove greater than at present, the end accomplished would more than justify the expense incurred.

It is desirable that that portion of the city streets traversed by the trolleys should be cleaned by them. Suction cleaning cars could readily be constructed, which would take up the dust between the rails and beyond to a distance of eighteen or twenty inches.

Conclusions.—1. Dust is dangerous, being (a) mechanically irritating, (b) infectious.

2. The following suggestions for the prevention of dust formation and littering of streets are recommended: (a) A campaign of education already begun to be carried on; (b) the present regulations preventing spitting on the sidewalks should be extended to the streets; (c) improvement in ash removal; (d) laws regarding the complete combustion of soft coal to be enforced; (e) dogs to be banished from the city streets; (f) cooperation of the police in enforcing the sanitary laws essential.

3. The present methods of street cleaning need to be supplemented (a) by more extensive use of flushing; (b) by use of suction cleaning automobiles.

The subways, connected with the streets and really a part of them, merit consideration, as they present problems as pressing as they are difficult of solution. Again there is seen gross misbehavior on the part of the public; spitting on the tracks in front of the station, and throwing upon them bits of paper and other unsightly articles; and on the part of the subway management, failure to properly remove the warm, stale air laden with dust, 61 per cent. of which is made up of irritant filings (according to Dr. Soper[11]). From the street dust sifts in through the open gratings, and from them in turn comes the contaminated subway air to be breathed by the pedestrians and residents on the higher level.

During the cool months, when the warm subway air rises rapidly, being replaced by the colder air from above, the conditions are not bad for one who would take a rapid journey underground; but during the warm third of the year such travel is undertaken with dread and endured only because of urgent necessity.

Improvement could probably be effected in the following ways:

1. The construction of the roadbed opposite the stations so as to admit of thorough cleansing with water. This would, of course, make alterations and repair of the tracks more difficult and costly.

2. Screening of the air coming in through the gratings.

3. The use of dust gathering cars, with funnel-shaped screens, to be sent over the tracks at times in the wake of the trains.

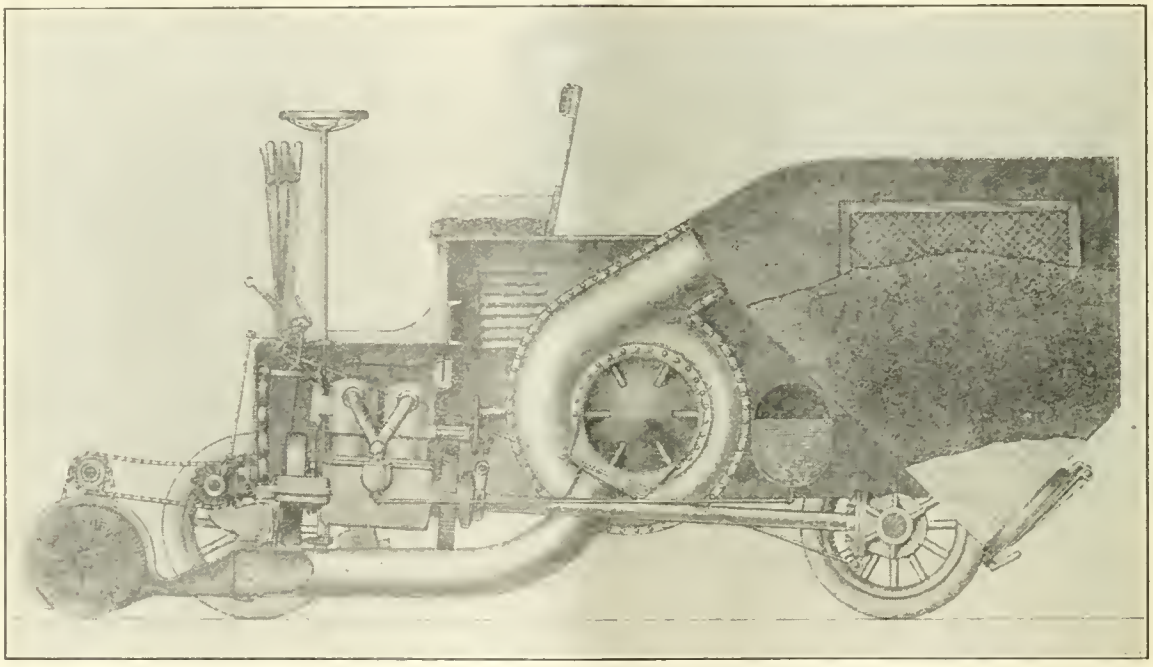

Fig. 3.—Plan of an automobile suction street cleaner, suggested by writer.

4. The construction of tunnels running into high stacks built in connection with the hotels and other high buildings along the route, through which the air could be sucked out of the subway by means of electric fans or hot radiators, being cleared of its dust at the same time by proper screening.

With the disappearance of the dust nuisance, New York would become one of the most beautiful, healthful, and delightful of the large cities of the world.

Shall not we, as a body of men interested in the welfare of all the inhabitants of this great metropolis, endeavor to secure for them one of the greatest of blessings—pure air? No others can speak with so much authority, or do more to bring this matter to a successful consummation.

A CASE OF MULTIPLE MYELOMA WITH ALBUMOSURIA.

By CECIL KENT AUSTIN, M.D.,

PARIS, FRANCE.

The patient whose case-history follows was a man of means, who in the course of his protracted illness sought advice from a large number of consultants of this city, the best available. The fact that no one of them made the correct diagnosis or even came anywhere near it, notwithstanding that in several instances they were warned that the attending physician's diagnosis was multiple myeloma with albumosuria, seems to warrant the belief that cases of this disease are yet of sufficient interest to justify publication in detail.

The patient, Mr. X., 72 years of age, was French and lived a life of ease, half of the year in town and the remainder in the country. His father, it seems, had been a man renowned in his day for unusual health and vigor, and had died suddenly at the age of 72. His mother lived to 87. Of the five children of this marriage, one died young, at 14; another at 42, of the heart; the remaining three were: A brother, a little younger than the patient, who suffers severely from hepatic disorder, gallstones, and jaundice; a sister of 52, who is in excellent health, and the patient himself, a married man with children and grandchildren, all in unexceptional condition. His remote personal antecedents were as follows: He was brought up in the center of France in a malarial region, and until the age of seventeen was considered so delicate that there seemed to be doubts as to the likelihood of his living. He was then, however, removed from his home climate to Paris and Dieppe, and kept there for five years; this change appears to have restored his health entirely. As a young man he fractured his right fibula in a hunting accident on horseback. This seems to have been a comminuted fracture, and Nélaton ultimately operated on it to remove a fragment of bone. This intervention was unfortunately followed by suppuration, which left a tiny fistula that Mr. X. kept to the end of his life. This detail is important, as it led to one colossal error in diagnosis. In 1868 he is said to have had cholera, and two years later he served in the Franco-Prussian campaign, during which he contracted pneumonia. We have then nothing special to relate about him for nearly thirty years, during which interval his health appears to have been excellent, after his rather stormy youth. In 1898 he first came under my care, at the age of 62, and I find in my notes the following: "Has had several sudden and violent attacks of lumbago for which he has been to Néris, and has also been treated by massage by a well-known Paris specialist." For several years after this he suffered from carbuncles of the neck each spring, but otherwise he did very well until June, 1906, when he had a sharp attack of cholecystitis with fever; some albumin was detected in his urine during the acute phase of this illness; but a complete examination, made shortly afterwards (June 25) by an analytical chemist, gave the following results: "Albumin, an evident trace, but imponderable; much calcium oxide, and a great excess of chlorides." We afterwards found a previous analysis, November 26, 1902, also made by a chemist: "Polyuria, 2.100 grams; very abundant chlorides; no sugar nor albumin." This attack of cholecystitis took place just two years before the albumose was first detected in his urine.

We now come to his immediate personal antecedents, whereby is meant the year that preceded the detection of his final illness (July, 1908), a year which he refers to as the most trying of his life. In the summer (1907) he went through a very hard electoral campaign. He next brought a near relative back to town in a serious condition of health, and busied himself with her affairs until she died three months later. He was a man who had charge of large financial interests connected with stocks, both for himself and his family, and for quite a circle of friends about him. The crash on the New York stock market in October and November caused him a great deal of anxiety, and in addition to this he was put to an endless amount of trouble with various lawsuits connected with his deceased relative's estate, so that by springtime he was very much run down, nervously. Already the winter before, his entourage had noticed that he was very irritable and that his hands trembled constantly, but this winter his condition in that respect became quite serious; he seemed unable to be still a moment, his hands shook shockingly, and he was up early, off out of the house as quickly as possible, and perpetually on the go. A noticeable detail with Mr. X. was his sexual vigor, which for a man of his years, 71, was quite remarkable, more in relation with an age of 30 or 40; this seemed to be a question that concerned his pride, and in order to keep himself up to what he considered the mark, he was in the habit of following tonic treatments of all sorts: The horizontal cold-water jet, electricity, strong solutions of strychnine, and hypodermic injections of glycerophosphates. His nervous state, then, was most likely due to three factors, business worries, undue sexual indulgence for his time of life, and his constant régime of tonics. During all of this winter he "felt his back," and was even treated for it by electricity. It was, however, looked on as the condition of lumbago, to which he had been subject for fifteen years. Yet one physician whom he saw that spring (May) is said to have detected a localized painful region over the spine.

He had just about finished with the troubles connected with his relative's estate when, toward the end of June, 1908, a friend suggested his having a uranalysis made, as he did not seem to be looking very well; but everyone was simply thunderstruck when the report came back showing a large amount of "albumin," 12 grams per 24 hours; polyuria, 2,900 c.c.; and chlorides, 29 grams. Mr. X. was then following a treatment by vibratory electricity for his back; so he showed this analysis to this physician, who put him on a milk diet, his weight then

being 73½ kilograms. But the "albumin" did not diminish under milk, the patient lost rapidly in weight, six kilos in the space of two or three weeks, and the pain in the back rather increased. Mr. X. then had recourse to an excellent consultant here, who stripped him and examined him thoroughly twice, on July 18 and 27, and seems to have been considerably puzzled, as his written memorandum reads as follows: "Abundant, aceto-soluble albuminura, without signs of nephritis." This man made a close examination of the spinal column, but could detect nothing; he took the patient off of milk, put him on fish and vegetables, and then insisted on his going for a cure to a French spa that specializes in kidney disorders. The patient did not reach the spa for another three weeks (August 17), during which time his dorsal pain steadily increased, and he continued to lose in weight and strength. At the spa he came under the care of a conscientious physician, who knows his business, and who described Mr. X.'s arrival in the following terms: "He came in a motor, not sitting, but supporting himself on his fists. The neuralgic attacks were as sudden in their appearance as in their cessation and were without visible cause. Mr. X. had been seized, some time before coming here, with severe attacks of pain of a neuralgic character, having their radiating center at about the right side of the second lumbar vertebra, and extending down both legs, immobilizing all the lower half of the body and giving rise to a horribly painful condition of muscular spasm each time that any movement set in action the lumbar center." This was an admirable piece of clinical observation, coinciding altogether with the facts in the case as they subsequently developed. The "albumin" at that time varied between seven and twelve grams per 24 hours, and was noted by this physician as "big albuminuria of an unusual form; albumin aceto-soluble, jellifiable." On his analyses he terms it "serin, globulin, albumoses, aceto-soluble albumin." This was the first time that the word albumose appears in this case. A blood-test then made showed erythrocytes, about 3,000,000, and leucocytes, 12,800. Under these conditions no spa baths were possible, any moving of the patient being liable to bring on those awful spasmodic crises. Rest in bed for a few days caused some sedation, but a week lated the neuralgic attacks began again worse than ever, leaving the patient no rest day or night. Considerable edema of the feet was also now present. Finally Mr. X. left the spa on September 13 for his home in the country utterly disheartened. He was there at once seen by a friend of his, a distinguished surgeon from a neighboring town. This confrère was further astonished at finding the spine deformed, two of the lower vertebræ seeming to project outward, with great pain on pressure. He immediately thought of spinal tuberculosis, with collapse of vertebræ and compression of the emergent nerves; still, from the letter written by him at this time it is evident that on account of the patient's age the idea of vertebral neoplasm was also hovering in his mind. Being a surgeon, he is discreetly silent about the medical feature in the case, the "albumin." On September 19 the patient traveled to Paris by train to seek further advice; he came from the station to his house in an ambulance, sitting in a chair, and I then met him for the first time since the detection of the present disorder.

When I had least seen Mr. X. in the spring he had been, generally speaking, in splendid condition for a man of 71; slender, perfectly erect; had it not been for wrinkles and white hair he could easily have passed for 40. Having never taken spirits, only wine at meals, as is the French custom; having used tobacco only in moderation and never smoked cigarettes, and having never had any venereal complaint, he showed no signs of arteriosclerosis, and his cerebral functions in particular were as active as they had ever been. But the man I now found was a different being; he had been literally transformed by disease and by much suffering. His flesh had simply fallen off his bones, and as he had always been very spare, he was now a sight. Three weeks later, when he had already materially improved, we found that he was nearly thirty pounds under his June weight; so the difference was most likely even greater on his arrival in Paris. His story centered in these crises of pain, consisting in the main of violent cramps of the thigh muscles, more particularly on the right side. Locally there was the projecting angle in the small of the back, very painful, red, and edematous. And on September 26 a uranalysis of the twenty-four hours, made by a biological chemist, showed: "total albumin, 29 grams (coagulating with acetic acid, 21 grams; aceto-soluble albumin, 8 grams); granular and colloid casts." The painful spine prevented the patient from lying in bed, and he was obliged to sleep propped up in his armchair.

He had come to Paris to consult specialists, so we began with two well-known men, both pupils of the late Charcot. The first one was evidently taken aback, and hesitated; but finally came boldly out and made a diagnosis of Pott's disease of the spine, connected possibly in some way with the tiny fistula of the right fibula that had existed for at least forty years. The albuminoid in the urine he thought might be due to amyloid degeneration, and he advised that a surgeon be asked to apply a plaster jacket for six months or a year. Mr. X. was simply horrified at this outlook, and asked for other advice; so we called in a specialist of great experience and sagacity, but who, on this occasion, I must confess, did not shine. This is the stranger, in that he made the patient three successive visits at intervals of a week, and had consequently ample time to rectify an initial erroneous impression. He seems to have been completely obnubilated, and his treatment was as weak as his diagnosis. He considered the situation as mainly a nervous one, the back condition as possibly senile osteoporosis, and the kidney affair as a separate disorder. Treatment: bromides, diet, and metallic plates on the thighs for the spasmodic contractions. This consultant had in various previous difficult conjunctures proved a tower of strength to me, but this time he failed. He let fall a remark, however, in the course of conversation that put me at last on the right track, so I suppose we must forgive his other shortcomings.

The painful seizures kept steadily increasing, hypodermic injections had to be given, and finally we reached the night of September 28-29, the climax of this phase. I have never in my life seen such suffering as I then witnessed for several hours; injections semed to have no action whatever; the patient's screaming and roaring could be heard at some distance up the street; he kept crying out for someone to knock him on the head; and I had finally to use chloroform. It was a terrible scene. What occurred during that night can only be conjectured, but it marked a radical change in the situation, and

put an end to the second phase of the illness. The first phase I consider the period of silence up to the latter part of June, when the "albumin" was discovered by chance. The second, the period of increasing pains that lasted fully three months, up to September 29. We then entered on a long phase of uninterrupted apparent improvement up to July of the following summer (1909), the third phase; followed by the fourth, the gradual cachectic decline, terminating April 29, 1910. It is possible to imagine that during that dreadful night the position of the collapsed vertebræ altered in some way, removing pressure or irritation of nerves that caused the suffering. However this may be, the pains soon came to an end altogether, the swelling and tenderness about the vertebral angle gradually disappeared completely; the deformity, though, remained unchanged to the end, but giving no trouble beyond the fact that Mr. X. could never again hold himself up quite erect after that, no matter how hard he tried. In the course of time his family all noticed that he had visibly lost in height. But a remark that my consultant friend had let fall, quite casually and without attaching the slightest importance to it, led me to look through some notes I had, and finally to come to the conviction that Mr. X's case was one of multiple myeloma with albumosuria. I then wrote to Dr. F. Parkes Weber of London, who I knew had devoted particular attention to this disease, and asked him to send me his important monograph on the subject. He not only did this, but made analyses for me, and aided me with his advice all through this difficult case; and I consider it not only a pleasure but a duty to make this acknowledgment of his assistance.

Dr. Weber's first analysis is dated October 10, 1908, and reads as follows: "Specific gravity 1020. Slightly cloudy. Medium color, acid reaction. 1. On heating test-tube in water, precipitate comes down when temperature of urine reaches about 54.5° C. Some of the precipitate (not all of it) redissolves on boiling; it reappears on cooling, and redissolves on again boiling, and so on. 2. This is better seen if the urine is first diluted with tap-water. 3. On adding strong acetic acid to the urine and then rapidly heating to boiling point, no precipitate comes down; but a precipitate can then occur on cooling, in which case it redissolves on again boiling, reappears on cooling, and so on. 4. The addition of acetic acid produces no precipitate, unless a few drops of potassium ferrocyanide be likewise added. In the latter case a copious precipitate occurs, which can be partially redissolved on boiling, reappearing on cooling, and so on. 5. Strong HCl and HNO_3 both cause a copious precipitate, which partially redissolves on boiling, reappears on cooling, and so on. 6. On adding strong HCl to the urine diluted with tap-water (one part urine in 20 parts water), a thick ring of precipitate forms at the junction-line of the two fluids (*i.e.* upper surface of the HCl). 7. On adding Fehling's solution, a violet coloration is produced, which changes to red on boiling." Dr. Weber concludes: "These tests, and the notes you give me, are quite sufficient to show that your case is a typical one of Bence-Jones albumosuria, or myelopathic albumosuria, as Bradshaw termed it. There cannot be the remotest shadow of doubt in the diagnosis." And he appended a very valuable hint in suggesting hypodermic injections of atoxyl as a line of treatment.

With such an endorsement as this I felt no longer any hesitation, but outlined a course of treatment for Mr. X. from which I never varied to the end; which succeeded fairly well since the patient's survival was two years all but two months, whereas the majority of these cases succumb within the year; but which was in constant opposition to the advice of our long series of consultants. The directing idea was to disregard altogether the urine analyses and look only to the patient's general condition and strength; to think only of building him up so that he should be able to protract the fight as long as possible, and for this purpose to let him eat and drink anything he wished. As an accessory to this main idea there was a certain amount of medical treatment. In default of any recognized remedies for this rare disorder we had to fall back on our ingenuity. I began with the atoxyl, and continued it at intervals for over a year; incidentally I tried *x*-ray courses, bone-marrow extract, and mercurial injections. The three latter gave no apparent result whatever; but the effect of the atoxyl was evident to everyone. It is conceivable that its action was no more than that of a general tonic; but all the same I should advise anyone else in the presence of a case of this disorder to give the method a serious and prolonged trial. Possibly modifications of the process used, or different doses, may be found still more beneficial; or the atoxyl might be replaced by arsacetin with advantage. In the interim we had made an attempt to take an *x*-ray photograph of the spinal angle, but had failed. The operator had the patient lie down on the plate, and the suffering was so acute that the patient moved and blurred the negative. On October 5 the "albumin" (as the analytical chemists here called the protein to the bitter end) was at 20.65 grams per 24 hours; on October 22, five days after the beginning of the atoxyl, it stood at 15.92, and on November 6, after the end of the first course of six injections of atoxyl, at 13.90. At the October 22 analysis the chemist noted: "This albumin is composed of three different varieties—one that coagulates directly, without acidification, at 54° C.; a second that coagulates in a similar way at 60° C.; and a last variety that coagulates at boiling after acidification; the proportions being 9.14, 6.34, and 0.44." But before beginning the atoxyl treatment I had a complete blood examination made by an expert, Dr. Charles Aubertin (October 16, 1908). The report was as follows: "Red blood cells, 2,650,000; white blood cells, 10,800; hemoglobin, 40 per cent.; leucocyte formula, polynuclear neutrophiles, 51 per cent.; myelocytes, neutrophiles, 2.5 per cent.; eosinophiles, 9 per cent.; mononuclears, 20.5 per cent.; lymphocytes, 8.5 per cent.; large mononuclears, 7.5 per cent.; nucleated reds, 1 per cent. Red blood cells: globular deformation very slight, but polychromatophilia and presence of basophile red blood cells in small numbers. Nucleated red blood cells: very few, but unquestionably present. They are normoblasts, or microblasts, or "free nuclei." No megaloblasts or atypical forms. White blood cells: presence of abnormal forms (myelocytes); there are classed among the polynuclears a certain number of neutrophiles that might be called "transition forms." The eosinophiles are clearly increased in number; most of them have a double nucleus as in normal blood, but a certain number have a triple nucleus. Again there are present a small number of eosinophile myelocytes with a single nucleus. No mast cells. The large mononuclears, with irregular nuclei and pale protoplasm (macrophages), are in greater number than usual. No Türck cells. No cellular

forms that might be interpreted as neoplastic cells. In short, marked anemia, without increase in globular value; eosinophilia, and very distinct medullary reaction."

In possession of these data, and the patient's weight being 60.5 kilograms, the treatment was begun on October 17, a hypodermic injection of atoxyl (0.20 gram) being given on October 17, 19, 21, 23, 25, and 30. From this time on improvement was marked and constant, and in order not to have to return to this point let me say that the atoxyl series was repeated at intervals in the following manner: Second series, 0.10 gram each, December 5, 8, 11, 14, 17, and 22. Third series, 0.20 gram each, February 28, March 2, 6, 10, 16, and 22. Fourth series, 0.10 gram each, June 1, 5, 9, 13, 19, and 25. The patient then left town for the summer. Another series was afterward administered between October 15 and November 10, six injections of 0.10 gram, and a final one between January 27, 1910, and February 11, also of 0.10 gram. The effect of these last two series was zero, the patient being then on the downward path and cachexia rapidly getting the upper hand. But during the first winter (1908-9) the action of the atoxyl series was remarkable. Starting from 60.5 kilograms, Mr. X.'s weight reached 62.25 on November 18, and 67.2 on March 25. The swelling, redness, and pain in the vertebral angle disappeared altogether. The foot edema became totally absorbed. Occasional discomfort in the hips, particularly on the right side, was experienced; but this did not last long. During these months he also complained now and then of severe pains over various ribs. He once more returned to sleep in bed, after having used only his armchair for weeks. His appearance once more became quite presentable, he commenced receiving friends at home, and finally began to go out again and resume his occupations one by one. His appetite was quite above criticism, and his spirits first class. He took to making desperate efforts to straighten out his spinal column and hold himself in his customary perfectly erect manner; but this he was not able to accomplish. In March he informed me that were it not for his annoyance on this score he felt perfectly fine. On April 1 he announced that he proposed to resume his former life where it had been broken off. And on July 9 he said he wished it to be known, before he left town, that he felt "extra-special-gilt-edged." All this time he was eliminating about 1,500 grams of a pale, cloudy, frothy urine, always containing the protein in large quantities; but the patient did not manifest a single symptom of nephritis. On December 1 the "albumin" was at 11.7 grams per 24 hours, and on December 30 at 10.2 grams, which was the lowest; for on January 16 it had risen to 12.7 grams, on February 17 to 12.3 grams, on March 26 to 17.7 grams, and on April 9 to 19.07 grams. Puzzled by these constant reports of "albumin," in spite of all that had been said, I on several occasions divided specimens, sending part to a chemist here and part to Dr. Weber. In each case the answer from London came back: typical Bence-Jones albumose, no doubts about diagnosis; while the chemist's report never varied from the usual: "albumin, coagulating at such and such temperatures!!!"

In correlation with the patient's general and striking improvement, noted from the time the atoxyl was begun (October, 1908) until the following March, there was likewise an improvement in the blood condition, affecting more particularly the leucocytes. The red blood cells, during those six months, reached 2.9 millions as their highest, while the hemoglobin got up to as high as 77 per cent. (from 40 per cent.); the white blood cells on the other hand descended from 10,800, first to 6,000, and finally to marked leukopenia, 2,000 to 2,600. But the interesting feature with the leucocytes was the gradual straightening out of the leucocytic formula. Thus, after the second series of atoxyl injections (December), the percentage stood as follows: Neutrophile polynuclears, 64.3 per cent.; eosinophile polynuclears, 1.6 per cent.; poly-mast cells, 1 per cent.; medium mononuclears, 24.6 per cent.; large mononuclears, 0.6 per cent.; lymphocytes, 7.3 per cent.; mast cells, 0.3 per cent.; which figures come very near to a normal analysis. During the second winter no further blood-tests were made. We then thought (erroneously as will be seen presently) that the situation had become complicated by a cancer of the rectum, and these tests seemed consequently of less interest. In the intervals between the atoxyl series, partly as an experiment and partly for moral effect, the patient was twice put on *x*-ray treatment at the hands of Dr. A. Béclère. The first series was given in November, three séances of ten minutes each, November 6, the spine only; and November 14 and 21, spine and hip both. Mr. X., however, then became so alarmed at tales of *x*-ray burns brought to him by his friends that he stopped the treatment. An attempt was again made at this period to get a photograph of the spine, in the erect position this time, but failed. The screen examination, on the other hand, turned out of great interest, showing a large number of black points in the lungs. Dr. Béclère inquired whether the patient had ever been the victim of a gun accident while hunting; but the true explanation was in reality quite different, post-mortem examination revealing a quantity of small calcified tubercles! In January and February we got Mr. X.'s courage screwed up again to a second course of *x*-ray exposures of the spinal angle of ten minutes each; he took six of them in all, at intervals of a week, between January 16 and February 20, but without any appreciable result so far as could be detected. In April (1909), in view of the marked increase in the albumose, the patient was put on extract of bone-marrow for quite a long period. He claimed that this treatment made him feel particularly well, and said that he noticed that his urine frothed less; there was, however, no visible difference in the albumose secreted. At that time I find in my notes: "liver, spleen, and kidneys apparently normal, neither palpable nor sensitive; no pain in back or bones." In May, 1909, his condition was so satisfactory that Dr. Du Bouchet, surgeon to the American Hospital here, made an incision at the site of the fistula of the right fibula and extracted the sequestrum that had been keeping it running for forty years or more, a little thing about the size of a match. The entire affair then healed up at once and for good.

This brings us to the summer of 1909, a year after the disorder was first detected. The patient was then away from Paris for four months, partly on Lake Geneva and partly at his place in the country. But in spite of the excellent opinion he had had of himself in the late spring months, it had already become evident that the maximum recuperation had been attained about April first, and that his resistance was now beginning to give way. The albumose, which from 29 had fallen to 10 grams, now steadily rose again to 17, 19, 20 and 22 grams.

and then oscillated about 20 grams per 24 hours until the end. As regards casts, the reports varied greatly. On July 8, 1908, there were none; this was also the case in the two very careful examinations made at the Spa on August 20 and September 11, 1908. On September 26, "granular and colloid casts" are noted; October 5, "a very few waxy and granular casts"; December 1, "a few waxy casts, occasional granular ones, and a few hemorrhagic ones"; and on December 30, "a few mucogranular casts." These were all in 1908. In 1909, none are reported; and on February 13, 1910, was noted: "no casts after centrifuging." In October I heard from the country that he was not nearly so well: urine very frothy, some leg edema, pains in hip and ribs, fingers cold, weight decreasing, bad color, much less energy, and considerable mental depression; so another course of atoxyl was suggested, but its action was now exhausted, and Mr. X. returned to Paris in November. I was then quite shocked to see how much ground he had lost in these four months; he was evidently on the downward path, this time, and the end only a question of a few months. Soon after this date two new symptoms appeared; his remarkable appetite left him altogether, he became fanciful over meals, and only nibbled at his food; and he developed signs of rectal tenesmus, with very frequent, small stools, sometimes consisting only of yellow mucus. At the same time he grew rapidly cachetic in color, something similar to good old wax. About January 1, 1910, I examined per rectum, but felt nothing, and the examination produced no pain. The same symptoms, however, continued, and even increased in severity, so that finally on February 11 I examined again, very carefully, and this time reached a lump, high up in the rectum, and painful. Tenesmus now disturbed the patient very much at night. I then asked Dr. Du Bouchet, surgeon, and Dr. Faisans, physician, to see him with me, and we all agreed that the rectal tumor could only be an epithelioma that had appeared secondarily to complicate the existing rate of affairs; postmortem examination, however, afterward showed it to be a lipoma. It was then decided, in spite of the patient's reiterated assurances that he had never had any venereal disorder of any kind, to try as a last resort a course of hypodermics of a soluble salt of mercury, which was done between February 15 and March 1, but without result. The next incident was an attack of acute pneumonia of the left base, lasting six days, and from which the patient recovered perfectly, in spite of his cachetic condition. In March I noted: "rectum tumor much more evident, consists of several lumps. Patient in bed most of the time, now, and eats little or nothing." This condition continued for several weeks longer, the end coming on April 29. He died from sheer cachexia, quite easily and quietly. His state toward the end was one of extreme, almost total, anemia, his tissues completely colorless, with great thirst for air, and extraordinary emaciation.

A chapter by itself almost could be written on the consultant side of this case. We had, as I said above, a great many consultations, and with the very best men of this city; but apparently this disease is practically unknown in France. They either went completely off the track, or diagnosed chronic nephritis. One very excellent man, of whom I have the very highest opinion, told me frankly, when I mentioned my own diagnosis, that he did not know the disease even by name. But particular mention is due to one of our last consultants, a young and much-thought-of professor at the Faculty here. He was told beforehand that the case was a very unusual one, and what diagnosis had been made, and Mr. X. went to see him alone at his office. He had then been ill for a year and a half, with an angle in his spine, pains in various bones, an average of 20 grams of protein in his urine all the time and yet not a sign of kidney trouble, although he was eating and drinking anything he wished, and with no history of syphilis, yet he came back with a detailed treatment for chronic nephritis! I then went to see this confrère, and he told me *viva voce* that his examination had not confirmed the diagnosis that had been made! It is to be hoped that if his eyes fall on the photographs that accompany this case-history they will enlighten his religion a little as to this very remarkable instance of chronic nephritis. Mr. X. not only saw all the best that was to be had, but indulged now and then in little *hors-d'œuvres* in the way of consultants, sometimes with my knowledge and sometimes unbeknownst. I had, fortunately, in his immediate entourage a friend *"à toute épreuve"* on whom I could rely absolutely. It was to this circumstance alone that I owe the fact that I was able to follow the case from beginning to end; had things been otherwise, my day would no doubt have been but a very short one. It was this relative who always kept me informed when experiments were being tried behind my back—for my patient's credulity in matters of treatment knew no limits but those of the universe. Anything any acquaintance advised, he wished to try; and as most of these treatments were harmless, and I had nothing better to propose myself, I generally assented, and the method was experimented with and very soon abandoned.

Toward the end, in presence of the conspicuous failure of the better portion of the profession to effect a cure, we dropped a little bit to the level of the "queer folk." Thus we were assisted for a while by a gentleman of laboratory convictions, who also (in the twenty-first month of the illness!) diagnosed the case as chronic nephritis, advised a treatment on the lines of pure science, and put the patient on a bouillon of decocted pigs' kidneys. Then we called in a homeopath. I consented to this step at the personal request of the staunch ally above referred to. This confrère had, of course, never heard of the disease either; but that did not worry him; he was not out after diagnoses, all he wished was symptoms. Of these we had more than enough to offer him, so he set to work: little powders all day long, nicely numbered, so that there should be no ill-feeling arising from No. 28 being by chance taken before No. 27, or after No. 29; in short, this stage of the case was decidedly trying. Another man whom Mr. X. saw on his own hook amused me not a little; he told the patient that he had had no experience with this disorder, and that the best advice he could give him was to go back to the physician attending him, "who seemed to have done fairly well"! This was certainly candid; but I must give quite a number of these confrères the credit for owning up at once that they knew nothing whatever about the disease.

In conclusion, the points in this case that seem to be of particular interest are the following: The long period of preliminary silence, which probably covered the entire winter of 1907-8. The period of increasing pains, lasting three months, ending in a big crisis, and followed by six months of uninterrupted improvement resulting in a condition that the patient considered practically a normal one. The

apparently favorable action of the atoxyl treatment advised by Dr. Weber. The fact that with a whole vertebra entirely destroyed (see necropsy report appended), and without the slightest artificial support, the patient suffered no inconvenience whatever from this pseudarthrosis, while at no time were there paralytic symptoms of any sort. The curious mistake, made by first-class men, whereby a perirectal lipoma was taken for a malignant tumor.

In view of the interest of this rare case, and the great diversity of opinions given concerning it, the family consented to have a detailed postmortem examination made by an expert. Dr. Nageotte was therefore asked to do this, Dr. Du Bouchet and the writer being present. His report is translated as follows:

"The body is extremely wasted; nevertheless there is still a three-centimeter layer of abdominal fat, and all the viscera are covered with fat. Thorax: The left pleura contains a little fluid; the right is entirely obliterated. In the apex of the left lung there are small calcifications surrounded by adhesions. The right lung is very difficult to remove, contains large calcifications throughout its entire extent, and its parenchyma is strongly emphysematous. The parietal pleura, which came away with the lung, is fibrous, and shows on its external aspect large patches of fat. The heart is covered with fat; its consistency is soft; the muscle is of a dead-leaf color. The mitral valve is a little thickened. There are two patches of old pericarditis, with adhesions about the cul-de-sac of the base. The aortic orifice, thoracic aorta, and arteria in general, are healthy and without atheroma.

"Abdomen: The entire deeper half of the lower aspect of the right lobe of the liver is adherent; the hilum is buried in a mass of fibrous adhesions that alter the shape of the gall-bladder. The liver is not increased in size; its tissue is not hardened; on section it has a nutmeg aspect with yellowish patches. The gall-bladder is divided into two halves by a partition, one of them containing a large round calculus, and the other several smaller ones. The wall is thickened and deformed by the peritoneal adhesions. The suprarenal capsules are hypertrophied and deformed; their surface is granular; the left one measures seven centimeters in length and three in width; the right, which was adherent partly to the wall and partly to the liver, was completely torn during the removal of the latter organ. The kidneys are surrounded by fibrofatty tissue of hard consistency. Their volume appears normal, but on section an enormous distention of the hilum is observed that is filled with fat; the renal substance, pyramids and cortex, is much reduced. Decortication is very easy, and exposes a smooth surface; the capsule, thickened and hardened, is infiltrated with fat; it remains rigid and retains the shape of the kidney when the latter is removed. The intestine shows no lesion; the mesentery is extremely fatty. In the pelvis there are large fibrous lumps of fat, hard to the touch, and simulating a tumor. The bladder is crowned with thickened peritoneum, and is hard and covered with fat; this fibrous shell would appear to have prevented the organ from emptying itself entirely. The spleen is adherent; its size is notably increased (15 centimeters in length). Its tissue is dark-red and soft. Lymphnodes: These were looked for in the mediastinum, mesentery, pelvis, and groins, but were everywhere very small and difficult to find.

"The bony system: The spine is deformed in the lower thoracic region; it has undergone inflection forward, with widening of the projection formed by the vertebral bodies. A portion was removed which at first sight appeared to comprise four vertebræ; but in reality it was found, after a fore and aft longitudinal section, that the twelfth dorsal body had entirely disappeared. The eleventh dorsal then tilted forward, the anterior edge of its lower surface resting in the middle of the upper surface of the first lumbar body. (See Plate.) The fibrocartilages are intact, except the one separating the eleventh and twelfth vertebræ, which is a little eroded behind where it is in contact with the remnant of the primitive tumor, visible in the posterior angle formed by the sliding of the eleventh dorsal over the first lumbar. There exists a secondary focus, the size of a hazel-nut, in the upper, posterior angle of the first lumbar body; two others the size of peas are visible in the substance of the second lumbar; finally, several smaller ones appear in the tenth and eleventh dorsal bodies. The vertebral arcs could not be examined. All of these neoplastic nuclei are composed of a dark-red central area, resembling currant jelly, with a thin, pinkish-gray edge. The bones in which they occur have in other respects retained a normal appearance. In the spinal column, as well as in the ribs, the bone marrow is yellow, which renders still more striking the beautiful ruby color of the tumor nuclei. Inside the thorax can be seen three metastases; in the sixth left rib, and in the fourth and ninth on the right side. These tumors manifest themselves by an ovoid enlargement of the bone; on longitudinal section it is seen that the tumor has hollowed out a space for itself in the center of the rib; at these points the surrounding bony tissue is reduced to a thin shell. (See Plate.) The tumors of the ribs have exactly the same appearance as those of the spinal column. The rapid and necessarily incomplete examination of the framework did not disclose any other foci. A portion of tibia examined as a term of comparison contained absolutely normal yellow marrow.

"Histological examination of the tumor of the left sixth rib: The tumor was studied in smears, and in sections prepared after fixation by means of Dominici and Zenker liquids. Sections were stained with Unna's polychrome blue, eosin-orange-hematin, eosin-orange-toluidin; the smears, with Ehrlich's triacid mixture. As had been indicated by the macroscopic appearance, the tumor is composed of two distinct zones: in the center almost total atrophy of the medullary elements has left nothing but the hematic sinus system. There exists in this portion a large hematic lake, divided up by the delicate walls of the sinuses; here and there is seen a starry center from which radiate the tiny fibers of the recticulated tissue that act as a framework. In this region are to be seen, mixed with the blood, different sorts of leucocytes: (1) Macrophages, charged with granulations of blood-pigment, in great numbers and of large size; (2) neutrophile and eosinophile polynuclears; (3) nucleated reds at different points of their evolution. All around this hematic lake there is medullary tissue, of a pinkish-gray color when fresh, constituting the vegetating portion of the neoplasm. The first detail that draws the attenion is the increase in the connective tissue; the fibroblasts and the connective reticulum have undergone manifest hypertrophy, and are far more apparent than normally. In this reticulum the myelocytes form clumps and prolongations, the outlines of which are marked by fat-cells. All cell varieties of normal

marrow were observed: (1) Megacaryocytes, few in number, characterized by their special shape, enormous size and budding nucleus; (2) amphophile myelocytes, with transparent nucleus, and protoplasm loaded with granulations that stain violet with eosin-orange-toluidin, reddish-violet with Ehrlich's triacid. These are by far the most numerous elements; (3) acidophile myelocytes, with large granulations that stain orange-red with eosin-orange-toluidin, and copper-red with Ehrlich's triacid. Some of them contain, in addition, basophile granulations, which are looked on by some authorities as young granulations; (4) eosinophile polynuclears, which are the same cells having acquired a bilobed nucleus; (5) basophile myelocytes, with transparent nucleus and homogeneous protoplasm, colored blue with the polychrome blue; (6) myelocytes resembling mast cells, very similar to the neutrophile myelocytes, but whose granulations are metachromatic in methylene blue; (7) nucleated red blood cells of the normoblast type. These elements, with nuclei more or less pyknotic and protoplasm homogeneous, are present in all their phases, with protoplasm more or less abundant, more or less acidophile, sometimes even downrightly basophile. Typical erythroblasts are also visible; (8) lymphocytes in very great numbers; these cells, owing to their enormous increase in this case, give the true characteristic of the variety to which the tumor belongs. I have already mentioned above the presence, in the central portion of the tumor, of macrophages loaded with blood-pigment; these are also present, though less abundant, in the peripheral zone. All these cellular elements are present either in their normal form, with the attributes that they possess in healthy marrow-substance, or in a state of caryolytic and plasmolytic degeneracy. Many nuclei are in pyknosis, and end in granulations scattered throughout the cellular protoplasm. It should be noted that caryocinetic forms are extremely few in the tumor.

"Yellow marrow of the tibia: This marrow is entirely fatty, but presents no special features. Lymph nodes: Several of these were examined, some from the mesentery and others from the groins. The former show an entire modification of structure; it is no longer possible to distinguish either cortical or medullary substance, everything has degenerated into a uniform layer of reticulated tissue, containing almost nothing in its meshes but lymphocytes. Those from the groin have undergone a similar transformation, with the difference that the reticulated tissue is broken up into little divisions by large fibrous bands; there is therefore here, at the same time, structure-change and connective tissue sclerosis. Spleen: Most of the cells of the spleen are in pyknotic caryolysis and in plasmolysis; it is probable that this is due, in the main, to putrefaction, for many large bacilli are visible in the tissue. This circumstance prevents any analysis of the modifications undergone by the cells of the pulp. All that can be said is that intense globular destruction has taken place, giving rise to a great abundance of ochre pigment. The framework tissue and the glomeruli of Malpighi appear normal. Liver: All the cells of the liver are heavily loaded with fat, and there is slight periportal cirrhosis. Kidneys: The kidneys are extensively sclerosed, particularly in the superficial zone of the cortex. A dense sclerotic tissue has been formed there, choking both glomeruli and tubuli. This process has manifestly originated in the renal capsule. There are no cysts.

"*Conclusions.*—1. The disease that carried off the patient was a myeloma, that is to say, a tumor of the bone-marrow, whose point of departure was in the substance of the twelfth dorsal vertebra, which collapsed through total disappearance of its bony substance. There are metastatic nuclei in the neighboring vertebræ, and in the ribs.

"2. This myeloma is characterized by the predominance of lymphocytes.

"3. The lymphnodes have undergone a form of atrophy, and a radical change of structure that is sometimes observed in anemia.

"4. There are evident traces of old and healed tuberculosis of the lungs. There are likewise traces of former inflammation of the pleuræ and peritoneum, which was no doubt also tuberculous. It is to this inflammation that the renal lesions appear to have been due."

DRUGS IN GASTRIC THERAPEUTICS.*

By J. W. WEINSTEIN, M.D.,

NEW YORK.

In the short time allotted to me for the reading of my paper it will be impossible to render a thorough exposition of the drugs employed in gastric therapeutics. I shall therefore confine myself solely to the pointing out of some of the most prominent features of these drugs, that may be of interest to the practicing physisian. A question is often asked, When is the proper time to administer rhubarb and soda—before or after meals? The answer is, It depends on what you wish to accomplish with the rhubarb and soda. The main effects of the rhubarb and soda upon the stomach is that of the alkali, the bicarbonate of soda that it contains. The effect of an alkali on the stomach, when given before meals, is to cause an increased secretion from the gastric glands. On the other hand, when the alkali is administered at the height of digestion, which for the stomach is about one hour after a meal, it neutralizes the acidity of the stomach. The element next in importance to the soda in the rhubarb and soda mixture, the rhubarb, causes an augmented secretion from the intestinal glands. The effect, therefore, of the rhubarb and soda mixture, when administered before a meal, is to cause a very much increased secretion from all the glands of the gastrointestinal tract. Through this augmented secretion the whole tract gets flushed out somewhat like an autolavage. If, therefore, a patient presents himself with a mild dyspeptic history of short duration, and we make up our mind to give him rhubarb and soda, the proper time to give it is before the meal. Should, however, the patient complain of a mild degree of constipation with some history of hyperacidity, such as heartburn, sour eructations, belching, etc., coming on about one hour after a meal, the proper time then, if we make up our mind to prescribe rhubarb and soda, would be to give it about one hour after a meal and thus exploit the antacid properties of the soda.

The Alkalies.—These are chiefly four: sodium carbonate and bicarbonate, magnesium oxide, also called calcined magnesia or magnesia usta, and ammonium magnesium phosphate. The effects of alkalies on gastric secretions, as I mentioned before, is that, given before meals, they stimulate the gastric secretions, while given after meals, when the stomach contents are acid, they neutralize the acidity of the stomach. As to their power of stimulating gastric secretion

*Read before the East Side Physicians' Association of the City of New York on December 1, 1910.

not all observers agree on this point. But all agree on the antacid properties of the alkalies. This antacid property renders the alkalies of very great service in hyperacidity, hypersecretion, Reichmann's disease, and also in gastric and duodenal ulcer, which are always attended by hyperacidity. Of the alkaline preparations the magnesium oxide is the best. It neutralizes four times as much acid as sodium bicarbonate. It also has very marked laxative properties, and since most patients that are afflicted with hyperacid conditions suffer also from constipation, this drug makes it the antacid of choice. Its dose is from 15 grains to about 1 dram, the dosage depending on the degree of the hyperacidity, to be given about one hour after meals in a little water. Where there is a tendency to diarrhea, calcined magnesia is contraindicated. As to the time of administration of the antacids, the height of digestion, about one hour after meals, is the proper time. It is better, however, to be guided in this respect by the sensations of the patient and instruct him to take it immediately before the impending symptoms, such as heartburn, etc., come on. It must be borne in mind, however, that heartburn, sour eructations, etc., do not always imply a hyperacid state. These symptoms are often present in subacid and even in anacid states, the reason being that in such conditions the mucosa of the stomach is often in a state of hyperesthesia and is most sensitive to the least irritation by an acid. The ingestion by such a patient of any acid, such as even a small dose of hydrochloric acid, lemonade, or vinegar, causes intense suffering. Moreover, anacid stomachs often contain large quantities of organic acids such as lactic, butyric, and acetic acids, which act as irritants and give rise to pyrosis, sour eructations, belching, etc.

Bicarbonate of soda is very extensively used as an antacid. In its alkalizing powers it is four times less potent than the magnesium oxide. Sodium bicarbonate has no effect on the bowels. Its dose is from 15 grains to 2 drachms, to be taken in water. Another disadvantage of this drug is that in neutralizing acids it liberates carbonic acid gas, while magnesium oxide does not do this, as may be seen from the following formulæ: $NaHCO_3 + HCl = NaCl + H_2O + CO_2$; $MgO + 2HCl = MgCL_2 + H_2O$.

Ammonium magnesium phosphate is also a good antacid. It neutralizes twice as much acid as bicarbonate of soda. The dose is 15 grains to 1½ drams. The sodium carbonate is less efficient than the others, being to a slight degree irritating to the gastrointestinal mucosa.

There is one important drawback to the antacid properties of the alkalies, namely, that while they neutralize at the moment of their administration the acidity of the gastric glands, later, however, the stomach responds with a reactionary secretion, and in about 45 minutes the acidity is greater than before. This is very unfortunate. There is one way to counteract this, and that is by combining the antacid with extract of belladonna, about ¼ grain to the dose, or with atropine, 1/100 grain, which checks the reactionary hypersecretion. In some cases we do well by making combinations of the various antacids. Another important property of the alkalies is their ability to dissolve mucus. In chronic gastritis, in which the mucous membrane of the stomach is covered with a layer of mucus, they serve a very useful purpose. The patient is told to put a teaspoonful of bicarbonate of soda in a tumbler of water and to drink it on an empty stomach. The patient shakes himself up vigorously from time to time and must not ingest his breakfast for an hour. This is a form of autolavage. Bicarbonate of soda serves also a most useful purpose as an addition to the wash water when we wash a stomach for chronic gastritis. It serves to dissolve the mucus.

Hydrochloric Acid.—This is a normal constituent of the gastric juice. Its presence is required in the stomach, first, to combine with the food and thus form the first stage in protein digestion, acid metaprotein, or, as it was called formerly, acid albuminate. Another property of hydrochloric acid is to activate the work of the pepsin, the proteolytic ferment of the stomach. Pepsin can do its work only in an acid medium, and the hydrochloric acid medium is the best one. Pepsin is not secreted as such in the stomach. There is a preliminary compound out of which pepsin is elaborated. This precursor or proenzyme of pepsin is known as pepsinogen, and the hydrochloric acid is the agency that converts the pepsinogen into pepsin. Hydrochloric acid serves also as a stomachic, a stimulant of the gastric secretion and improver of the appetite. It is self-evident that whenever there is free hydrochloric acid in the stomach, to prescribe this substance is superfluous. We therefore restrict our prescriptions of hydrochloric acid to cases of subacidity and anacidity only. This treatment, even in cases of subacidity, is very far from ideal, for we can never supply the deficiency of hydrochloric acid. The quantity of this acid required to satisfy the affinities of the foodstuffs is enormous. Honigman and von Noorden have shown that one part of pure hydrochloric acid can saturate only 18 parts of egg albumin. It would take, therefore, 10 grams, or 150 drops, of the dilute acid in order to saturate 18 grams, or slightly above one-half an ounce, of egg albumin. The quantities of hydrochloric acid required are, therefore, enormous, quantities unsafe to administer, for we can never imitate that wonderful mechanism of nature in the stomach, whereby each of the 5,000,000 little glands is spouting out hydrochloric acid in a most gentle, uniform, and steady microscopical spray! Who can produce such a marvelous hydrochloric acid shower bath? As long as we cannot do this our hydrochloric acid therapy will remain far from ideal. More than that. A good many anacid stomachs are in a state of hyperesthesia and cannot stand the least contact with acid. And it is especially those cases of subacidity that show the very lowest acidities, such as from 4 to 8 of free acid, that are most vulnerable to hydrochloric acid. We see, therefore, that we can never hope with our therapy to fill up the hydrochloric acid shortage within the stomach. There is, however, another indication for this acid, namely, as a stomachic. As a stimulant of the appetite it serves a real useful purpose, and most gastrologists employ it solely as such, given 10 to 15 minutes before meals, in one-half glass of water, in doses of between 10 to 20 minims of the dilute acid. Hydrochloric acid has a deleterious effect on the teeth and should be taken through a glass tube.

Pepsin.—This is the proteolytic enzyme of the stomach. It digests the proteins. It plays a very small rôle in gastric therapeutics. It has almost been abandoned by gastrologists. Pepsin is always present when hydrochloric acid is present. Even when the latter is absent, pepsin is usually present, especially the proenzyme of pepsin, pepsinogen, and the latter can be readily activated through the addition of hydrochloric acid, so that this alone is sufficient in such cases. Even if there is absolutely no

pepsinogen present the patient can get along fairly well as long as the motility of the stomach is good. Nature has endowed the digestive tract with several enzymes, so that when one gets out of commission the other one takes its place. There is besides the pepsin also trypsin, and then erepsin, and finally the bacteria of the digestive tract possess enzymatic action. Pepsin works in an acid medium only and should be combined with hydrochloric acid. Pepsin should never be prescribed with bicarbonate of soda or rhubarb and soda, as is often done, for it works only in an acid medium. Pepsin in combination with an alkali is an inert substance and adds nothing to the patient. If any one gets some results from such a combination, he gets it from the alkali and not from the pepsin. In prescribing an enzyme a reliable preparation of a manufacturer of the highest repute should be required. However, there is another factor to reckon with in this connection—the druggist. He has a good deal to say about it. The powder only should be prescribed. The wines and alcoholic forms are no good, for pepsin is not very soluble in alcohol. Its dose is from 7 to 15 grains after meals, best administered with hydrochloric acid.

Pancreatin works only in an alkaline medium. Its use is very limited. It is even more limited than that of pepsin. To give it in any case where there is acid in the stomach is worthless, for it cannot work in an acid medium. To expect it to work in the intestines after its transit through the stomach is fallacious, for it gets destroyed by acid and pepsin. To hope that through the addition of an alkali which will neutralize for a time the stomach contents, the pancreatin will be enabled to work, is again valueless, for this means to throw out of commission the pepsin, which cannot work in an alkaline medium. There is one plan of getting its effects in the intestines, and that is by administering it in a keratin capsule, which is supposed to resist the action of pepsin, but is dissolved by trypsin. Some put it also in salol or gelatin-coated capsules. This procedure, however, is very unreliable. There is only one field of usefulness of pancreatin, though a very limited one, and it is in those cases of total absence of hydrochloric acid where the mucosa of the stomach is hyperesthetic and cannot stand any acids at all. In a case like this, one will at times benefit the patient by giving him pancreatin and thus converting the stomach digestion into an alkaline process. Pancreatin is best given in powder or pill form in doses of 10 to 30 grains, with 20 grains of bicarbonate of soda.

The Bitters.—Their main effect on digestion is as appetizers. Since Pawlow has shown that the appetite is the main factor in causing gastric secretion, the bitters may be looked upon as stimulants of gastric secretion. The best of the group is condurango. The fluid extract is probably the best preparation. It is given in doses of about 30 minims. The tincture of gentian and the elixir of gentian are good preparations. Strychnine, tincture of nux vomica, tincture of cinchona, and hydrochloric acid may all be put as belonging to this group. It is a very good idea to make up combinations of these drugs.

Bismuth subnitrate is probably the greatest drug in gastric therapeutics. We get the best results with it in the following conditions: duodenal ulcer, gastric ulcer, and hyperacidities. Its effects are instantaneous, almost from the first dose, and it not only relieves the pain, but also cures the ulcer in many cases. It works only when given in a big dose, 5 grams per dose, stirred up in a tumbler of water once a day in the morning on an empty stomach. The patient is instructed not to ingest anything for one hour subsequently. The bismuth spreads itself out all over the stomach and soothes and heals the inflamed and eroded gastric mucosa. It may also be given twice a day in doses of 3 grams each, always on an empty stomach. I have never seen any untoward effects from it. The bowels are in most of the cases regular under this régime. At times a slight constipation supervenes, which is very easily relieved by the administration of calcined magnesia in doses of 15 to 20 grains, given three times a day about one hour after meals, which also helps to reduce the acidity. Some patients derive mild laxative effects from the bismuth, and I heard on more than one occasion the remark of patients, "Doctor, I have been feeling fine since you gave me the physic."

Cerium oxalate is an excellent drug to check vomiting in diseases of the stomach. It stops vomiting in carcinoma of the stomach. It works very efficiently in all cases of vomiting of gastric origin, where there is an organic disease of the stomach, such as carcinoma ventriculi, ulcus ventriculi, chronic gastritis, etc. It does not stop the vomiting of the gastric neuroses such as nervous vomiting, nervous regurgitation, nervous dyspepsia, etc. Its mode of administration is 5 grains per dose in powder form, in half a glass of milk before meals.

The Malt Preparations.—If grain is allowed to germinate the starch is converted into sugar. This splitting up of the starch is due to an enzyme called diastase. Malt preparations are charged with diastase and are administered to patients with the idea of the diastase promoting the starch digestion within the stomach. Unfortunately in a good many of these preparations the diastatic enzyme has been destroyed by the heat employed in the process of preparation. A good many of them are adulterated. They are, however, palatable beverages and contain some nutriment. They are also good as stimulants. A good many of them contain alcohol and cannot be distinguished from beer or stout. Besides the malt preparations there are others that are lauded as powerful starch digestants. There is no doubt about it that they do digest starch in a test tube to perfection. In practice, however, I found them to be a total failure. We have within us, in our saliva, an enzyme, the ptyalin, which is superior to any of them. It is perfect in its action and is never out of order. It must, however, have the proper medium for the proper performance of its work. It works in a faintly alkaline and neutral medium. According to Chittenden and Smith it works best in the presence of combined acid. It cannot work in an acid medium. Its work is, therefore, defective in all conditions that are accompanied by hyperacidity. The same, however, holds true of the proprietary starch digestants that are on the market. They are powerless in hyperacid conditions, and where are their virtues and advantages? The term "amylaceous dyspepsia," so promiscuously vaunted and flaunted before us as being checked at once by the artificial starch digestants is nothing else than hyperacidity and is not a bit checked by them.

There are products on the proprietary market which contain a combination of the various enzymes of the body. They contain ptyalin, pepsin, pancreatin, and what not. It is a most unscientific and most useless team. It reminds one of the old fable where a swan, a lobster, and a pike undertook to drive a wagon. The swan was pulling skywards,

the lobster was pulling backwards, and the pike towards the river. It may well be imagined how much progress this worthy team has made. Just as much progress will our enzyme team make. Each enzyme works only in its own specific medium. Thus pepsin works only in an acid medium, pancreatin in an alkaline, and ptyalin in a neutral medium. Moreover, the various enzymes tend to destroy one another. That pepsin destroys trypsin was proven by Pawlow, and how can they be put together in one team? I pronounce them absolutely useless not only from theoretical considerations, but also from actual practical experience, having given some of these preparations a thorough and impartial trial. If any one gets any results from them, he gets them not from the treatment, but in spite of the treatment.

71 East Ninety-Sixth Street.

THE SIGNIFICANCE OF A HISTORY OF ALCOHOLIC ADDICTION.

By T. D. CROTHERS, M.D.,

HARTFORD, CONN.,

SUPERINTENDENT WALNUT LODGE HOSPITAL.

A very prominent man suddenly presented an array of symptoms which were the subject of widely differing opinions by leading men in New York and New England. His history indicated that during college life and later at the beginning of his professional career he had used spirits so freely as to alarm his friends, and had become the subject of much anxiety. Suddenly he appeared to change his habits of life, and while not a total abstainer rarely drank in public and claimed to be a temperate man. His business and professional career had been very successful, and so far as could be ascertained he had been well and seldom consulted a physician. At fifty years of age he suddenly developed symptoms of great prostration and muscular feebleness. At times he had acute dyspepsia, constipation, and diarrhea. He would be very greatly depressed or unusually buoyant. The reflexes varied from time to time. The arterial tension was low. A great variety of symptoms appeared from time to time, then passed away. The excretions were alternately normal and abnormal. Insomnia and pronounced stupor followed each other. These combinations of symptoms were inexplicable, and many skillful diagnosticians differed widely as to what the conditions were and as to the various means of treatment. Some of these were very heroic and were followed by diverse results. Travels to Europe, consultations with specialists, and the constant care of a family physician who went about with him and was supposed to be in close touch with him all failed. Finally the collapse deepened into coma and death. The undertaker found a quantity of morphine in the little bag covering up the crucifix suspended around his neck. Inquiry among his intimate friends brought out the fact that a wholesale druggist for years had been supplying him with small quantities of morphine, and this had been done with great secrecy, and on the supposition that it was to be used for an invalid brother who was paralyzed. In reality the case was one of concealed morphine addiction, probably associated with the use of cocaine in exceedingly small quantities.

Another case occurring in New England was equally baffling to many physicians. A very wealthy manufacturer suddenly began to show signs of dementia and weakness. He, too, went the rounds of consultants and had with him a family physician. After two or more years of apparent great effort to secure medical aid it was ascertained that he was addicted to the use of morphine and bromides alternately. Later he died of acute pneumonia, and only his family knew of the real causes. There had been a history of alcoholic excess in early life, but during the later years of his life he had been temperate and had been supposed to be healthy and well.

While these cases represent extreme types, they suggest conditions that the average physician is very likely to overlook. In all obscure cases of both neurotic and nutritional disturbances a history of early excessive use of spirits should suggest many things which may possibly act as both exciting and contributory causes. A person who suddenly abstains from the use of drugs and spirits and who both claims and appears to be in good health and fully restored is open to the suspicion of secret drug taking, particularly of some of the narcotics. An unusually buoyant optimistic person who boasts of his escape from spirit and drug addictions is not unfrequently found to be using cocaine. This for a time gives unusual exaltation and delusions of health and strength that are always suspicious. Sometimes it develops garrulity and boastful confidence in one's ability to overcome all sorts of obstacles. There is no drug that will so pronouncedly change the feelings of pain and discomfort as cocaine, and some persons are very susceptible to its use in small doses and are able to use it for a long time without any apparent injury except an unreasonable optimism followed by conditions of abstractedness. Fortunately, these persons are not very numerous, and the ordinary effects of the drug are very quickly determined or suspected by close observation. Chloral and bromide compounds frequently are used to break up the after-effects from drugs and spirits, and these may be taken secretly for some time. The effects are uniformly depressing, with a tendency to produce sleep. Short periods of buoyancy, with long, quiet, depressive intervals, are the usual symptoms. A pronounced failure of energy, with hesitating utterance, abstract manners and air all suggest drugs of which bromides are the most common.

Another drug which has peculiar after-symptoms, especially in cases in which alcohol has been used for any great length of time, is cannabis indica. A number of cases have been noted in which disorientation is prominent. Persons will suddenly become forgetful of their surroundings and be unable to locate themselves, and show a degree of abstractedness that is very unusual. Later it is found that they are taking some combination of cannabis indica which, while quieting their nervous system, has this peculiar local action. At the time this is attributed to some other causes.

Many narcotic drugs are combined so that little more than a general anesthetic action can be traced These combinations produce very misleading symptoms that suggest other diseases and are often very puzzling to the physician because of the rapid changes which follow. The central fact should always be recognized, namely, that previous addiction to alcohol and opium has produced or may produce some central degeneration that is seldom if ever repaired, and that in later life, when disease, either inflammatory or specific, appears, these conditions are to be considered. Syphilis is a very important factor in the history and treatment of many dis-

eases occurring many years after the specific infection. Clinical experience shows this in the rapid change and disappearance of symptoms following the use of mercury, symptoms that were not referable to the specific disease which had occurred long before, but the fact that mercury relieved them was a strong presumption that these symptoms were more or less connected with a previous infection. In very much the same way the use of alcohol extending over a period of years and followed by frequent intoxications undoubtedly impresses the organism and lowers the vitality, and in some unknown way this is strikingly manifest in the traumas and inflammations and other degenerations that follow. In studies of life insurance this factor is always considered and inquired into with some minuteness as one that has much bearing on the longevity of the person. The commonly accepted theory that alcoholic poisoning is a transient condition and one in which recovery is perfect and complete is not sustained by actual experience, but, on the contrary, there is greater susceptibility to disease, increased mortality, and lowered vitality and resistance in such persons. The evidence on this point is very pronounced and is confirmed in everyday practice.

Typhoid fever occurring in a man in middle life or some acute affection of the lungs will vary widely, with more intense symptoms and greater mortality in persons who have previously used alcohol or have been addicted to the use of drugs. Curiously enough, consumption is found to be more intense and pronounced in such persons, and the old theory that its use was a preventive remedy has not been sustained. Consumption is almost necessarily fatal in every case with an alcoholic history. Rheumatism is another disease which seems to follow in later life the alcoholic addiction, and to be very difficult to treat. We now know that neuritis, the common sequela of the excessive use of alcohol, leaves a special predisposition to appear from almost any toxemic cause, hence rheumatism following the use of alcohol, even years afterwards, is very likely to be greatly intensified and more profound in its invasion and persistency. Disturbance of digestion, either well defined or obscure, has a very close connection with the use of alcohol and drugs, and when this fact in the history is established both the diagnosis and prognosis can be made with much greater certainty. Arteriosclerosis and cerebral hemorrhage are very often traceable to alcoholic excesses long before. In a study of ten cases of cerebral hemorrhage the fact came out that six of them had at some previous time used spirits to excess, then had abstained. There can be no question that syphilis leaves a predisposition to these affections, perhaps not as pronounced as that left by alcohol.

In a recent report by Dr. Lagrain of the Municipal Hospital for the Insane in Paris, France, he asserted that fully 60 per cent. of the mortality cases were traceable to alcoholic degenerations in their previous history. This was further confirmed in a recent address by Dr. Savage of London, who stated that an alcoholic history in both acute and chronic cases was of equal significance to that of syphilis, and should be sought for as a most important factor, bearing on the question of prognosis and treatment. Often cases appear in which there seems to be a peculiar susceptibility to the action of alcohol, even in the form of a tincture, or if the thoughtless physician suggests a mild wine or beer, the patient will become extravagant in his praise of its particular medicinal action. There are two facts which are to be sought for in such cases, namely, a previous use of spirits which leaves an entailment or special favoring influence for the anesthetic effects, and there is some special exhaustion or defect in the nerve centers which this drug covers up in a most pleasing way. The wise physician will recognize this constitutional susceptibility and seek to replace these remedies with others less dangerous. It is almost certain that these peculiarities will produce some addiction to this or allied drugs to the great injury of the patient.

It not infrequently happens that physicians find their patients relying on certain mixtures which are known to contain opium or its alkaloids or large quantities of spirits. This in itself is of great significance in many ways. The condition for which the patient requests treatment will vary largely, and depend more or less on the action of the drug he has used, and this must be considered in the prognosis and treatment. A case of unusual interest was that of a man who during his early professional life was an immoderate beer and wine drinker. He then abstained and acquired great wealth and eminence. At about fifty years of age he became an invalid, and after the usual confusing diagnosis and efforts to determine his particular disease he was found to be a morphine taker. A crude, ineffectual effort to withdraw the drug brought to light several very distressing conditions and a council of friends decided it was better to continue its use in small quantities. This he did for a few months. He died suddenly from pneumonia, and an irregular, strange will was contested. The question came up concerning his mental condition. A number of physicians, as usual, gave opposite opinions concerning his testamentary capacity. The will was sustained. The evidence was unmistakable that for years he had been a secret drug taker. Of necessity his mind was more or less impaired. The facts of his early drinking seemed not to impress the experts who decided on his mental capacity. In this they were in error. Another class of cases bearing on this subject are those of unusual deliriums and comas following traumas or toxemias. The physician is astonished at the prominence of these symptoms and sometimes his treatment is very thoughtless. A previous history frequently brings out the fact of excessive spirit or drug taking, and this is readily traceable in the profound variations and changes which occur that are not usual from the ordinary causes. These cases are very significant, and should be recognized, but at present they constitute a very obscure field of practice that is yet to be studied.

SHORT TALKS WITH MY STUDENTS AND OTHERS: BEING RANDOM SUGGESTIONS FOR THE YOUNGER PRACTITIONERS.*

By ROBERT H. M. DAWBARN, M.D.,
NEW YORK.

Flowers at Night.—All doctors know that it is considered best not to keep flowers or plants in a sickroom at night. But why? Flowers possess three prominent functions, so far as they affect at all the air about them. (1) *Transpiration;* they give off moisture taken up from the soil; hence the

*See MEDICAL RECORD, April 15, 1911.

air is somewhat humid if many—particularly growing plants—are kept in the room. (2) *Respiration;* they act much as we do as to this; they use up oxygen, and in exchange give off carbonic dioxide. (3) *Photosynthesis;* this is the name given to the action of sunlight upon the stems, leaves, and all green parts chiefly. It is the reverse of the result of respiratory activity, as just stated. That is, so long as there is daylight, carbonic dioxide is taken in, and oxygen given off, by photosynthesis; consequently, until night time arrives, No. 2 and No. 3 may be said to balance each other, leaving neither good nor ill results. But, during the entire night, Nos. 1 and 2 continue their activities, while No. 3 is temporarily suspended. No. 1 is not objectionable; but No. 2, without No. 3 to balance it, acts (in principle but not in amount) until the return of daylight, just like an additional person breathing in the room, thus leaving a little less oxygen for the use of the invalid. Therefore the standing order, to remove all plants or flowers at night, is based upon the facts of plant physiology, and is right.

When to Ask no Questions.—When, during a difficult operation and in a reasonably cool operating room—one in which nobody else is perspiring—the bystanders begin to see drops of sweat appearing upon the forehead of the operating surgeon, and, it may well be, glistening too upon his dome of thought, ask him no questions! This is no time to distract his attention from the problem in hand. He is having troubles of his own, and is realizing them.

Never Lose Your Temper while operating (nor at any other time—but while operating, never!) Neither throw implements nor imprecations across the room. To scold because of a dull knife, for instance, simply proves you duller—and a poor disciplinarian. Let your orders be given barely above a whisper. Let your face never lose its cheerful calm; nothing so impresses onlookers with the (very possibly erroneous) conviction that here is a masterly surgeon! And yet there are limits: A warm friend of a certain operator of national repute once remarked of him: "I do believe that if Dr. X. were to cut across the abdominal aorta, in the course of a laparotomy, that same cast-iron smile would not leave his face."

Never Be Pitiless Toward Pain and Poverty.—I am sure it is through thoughtlessness rather than deliberation that so often internes, and the nurses following their lead, address the unfortunates in charity wards roughly. Regarding the women, though poor always, no one before has failed of the respect implied by addressing them as Miss or Mrs. —— as an instance of what I mean. It hurts these poor creatures to hear the house physician say: "Sit up, Smith; I want to listen to your chest." They have nothing to think of all day, and day after day—these sad-faced women—but their troubles, and his words during his daily rounds; words cheery, kindly, and courteous—or the reverse.

Never Try to Prophesy, a request to attempt which will almost be forced upon you, and frequently. On one occasion the senior Nelaton was asked by a lady patient to state about how long her case would take in order to effect a cure. "Madame," was his reply, "I make the wound; also I do the dressing; but the Lord does the healing. You are therefore asking the wrong person." I have repeatedly found it worth while to quote this little story to patients. Only the youngest doctors are found willing to forecast the future with any attempt at exactitude. An occasional brilliant success by no means balances the frequent resultant mortifying failures.

How Many Pounds' Traction (against elevation of the bed-foot, as counter-traction) should be our rule in dealing with oblique fractures with overlapping fragments in the lower long bones? The only definite rule I have encountered, and that far from a reliable one, is Hamilton's; namely, a pound for each year of the patient's age, up to about 20 years. Let us first remember that it is agreed as being a practical impossibility to use enough pounds to pull the fragments past each other, thus resulting in a broken bone that ultimately is lengthened in consequence of such traction! This happens in the case of the patella and olecranon, but never in long bone fractures. Since this does not occur, the proper rule seems obvious: *Use as many pounds as possible, short of spoiling the patient's sleep.* I have repeatedly found the patient capable of tolerating thus quite a number of pounds' pull more than would correspond with Hamilton's rule; however, as giving us an average starting point it is well to remember it—assuming that after the age of 20 the weight to be first tried, with Buck's extension, may be this number of pounds. This we try to increase to the limit of toleration, or lessen, under compulsion of broken rest, which, of course, must not be permitted.

The Apostolic Hand is the name which for twenty-five years or longer my students have used rather than "Dupuytren's Contraction." Of course no irreverence is intended. The point is, simply, that the customary title tells the student nothing as to the appearance of the member thus diseased; whereas that which the writer suggested gives an instant mental picture of such a hand, with the fingers most often involved bent down into the palm by the scar-tissue contraction. The "apostolic hand" is so named as being the posture which prelates have ever used while delivering a benediction. The order of frequency—as to relative involvement of the digits—is 4, 5, 3, 2, 1.

About Dislocations.—What causes them, generally speaking? *trips*—surely! And by the same token you may remember how many kinds of dislocations there are. Their number is ten; of these five may abide in memory the better by aid of the letters of the word *trips*, used as an acrostic; and the other five varieties are the natural opposites, so to speak, of the five first named, as follows:

Traumatic *vs.* Pathological.
Recent *vs.* Old.
Incomplete *vs.* Complete.
Primary *vs.* Secondary.
Simple *vs.* Complicated.

A few lines in explanation: By a *pathological* dislocation is meant, for instance, one at the hip-joint, due to tubercular absorption of the femoral head, as distinguished from the ordinary, the traumatic causation. By *incomplete* is meant, of course, subluxation; the subcoracoid at the shoulder-joint, for example. By *secondary*—if in reducing the commonest type at the hip-joint, *i.e.* that upon the dorsum ilii, the operator by mistake throws the head of the femur into the thyroid foramen instead of into the acetabulum, a *secondary* has thus been made to replace the *primary* dislocation. A *complicated* dislocation may be compound, *i.e.* "open"—terms used with the same meanings as in fractures—or may be associated with torn nerves, vessels, muscles, etc., or with fracture involving the joint.

MEDICINE AND THE FOLKWAYS.

IN the modern warfare waged against disease in its myriad forms there are moments when the attacking forces must pause to take account of the victories won and the defeats sustained. In reviewing the progress of their work sanitarians must ultimately answer the questions: Have the results been commensurate with the efforts; would any other plan of battle have assured a victory at a smaller cost? The first answer to these questions would be to gauge success in terms of money; to reduce the problem of safeguarding health and prolonging life to a simple task of business accounting. The statement is frequently made that if sufficient funds were available for carrying on the work certain scourges of humanity could easily be annihilated. With pride many communities point to their philanthropists' donations of millions for the endowment of laboratories and hospitals, as if the magic wand of Pluto could scatter the grim emissaries of suffering and death. In an era when to many minds success is spelled in terms of dollars one is apt to forget if not to ignore that there are other important factors in the health crusade besides financial endowment.

One of the greatest drawbacks to success in the hygienic movement has been the tendency to regard disease as an impersonal element—something to be fought apart from the individual and irrespective of the feelings, the habits, and even the comfort of the afflicted. Methods of isolation of the sick, and the quarantine of those exposed, compulsory regulations pertaining to elemental personal inclinations have been framed without regard to the emotional element. The vast machinery of public sanitary supervision with rare exceptions takes no cognizance of the individual, his conscience and belief, his whims and settled convictions. That this should be the case is easily understood if one considers the practical impossibility, in the development of this machinery of public sanitary regulation, of regarding the individual apart from the welfare of the community of which he happens to be a mere unit.

If this impersonal attitude were confined to public measures there would be little cause for criticism or complaint. This attitude, however, dominates private schemes of philanthropy, hospitals, homes, and sanatoria, fresh-air funds, and the multitude of other charitable provisions for the welfare of the sick and poor. The charity patient is admitted to the hospital ward, and treated according to the most advanced methods of modern medical science; nevertheless he rarely escapes the feeling that he is in bed No. 6, in the male medical ward, a case of typhoid fever or endocarditis, and that so far as the hospital is concerned he is not John Smith, "how noble in reason, how infinite in faculty, in form and moving how express and admirable!" In other words, the patient's craving for sympathy is usually ignored in the mechanical routine of the day's work. Beverley Robinson has recently alluded to the failure of the average hospital physician, in his zeal to cure the cases that respond to treatment, to do everything in his power to assuage the suffering of the incurable and of those who are expected to die. If this is unfortunately true in some instances how much truer it is in the case of the mental anguish, the dreary isolation, the longing for friends, and the touch of a tender hand, that are so often disregarded in the modern business of curing the sick.

This subject leads to the larger one that is intimately associated with the settled habits, customs, and conventions of the race, which Professor W. G. Sumner terms the "folkways" and has so admirably discussed in his volume upon this subject. These elemental instincts that are centered in the love of home and of kindred, in the yearning for personal liberty, and in the pursuit of happiness must be taken into account if one would successfully prosecute the campaign against the foes of health. All charity workers are probably familiar with these fundamental traits and many of them doubtless make an allowance for satisfying these human needs. Money cannot always take the place of kindness and sympathy; no charitable scheme is considered wise that will part the widowed mother from all of her children, that will disrupt the home, or will disregard the religious convictions of its suppliants. Do health workers recognize the same human needs? Do they take into consideration the folkways in their elaborate plans for bettering the sanitary conditions of the people? The answer to this question is unfortunately a negative one, unfortunately, both for the individual for whom these plans are formulated and for the successful consummation of the work of public health betterment.

Recognition of the folkways will restrain the enactment of arbitrary sumptuary laws that defeat their own purpose by running counter to the personal liberty of those for whom these laws are designed. Philanthropic schemes that may be framed for the purpose of sending a consumptive to a distant sanatorium are doomed to failure, because the sufferers will rarely apply for this voluntary exile from home and friends. The ideal sanatorium is one built at no great distance from the homes of the patients so that relatives may have an opportunity of visiting the sufferer at reasonable intervals. Even the sanatorium will not adequately supply the needs of the large number of consumptives who are compelled to work for their families' support. The need has been recognized of building houses and tenements in which the tuberculous may remain with their families and at the same

time enjoy the advantages of the fresh air treatment. The era of phthisiophobia is nearing its end. The tuberculous individual is no longer to be regarded as was the leper of yore—or, alas! as is the leper of to-day—but is to be treated as one who with the observance of reasonable precautions cannot be a menace to his fellow beings.

The attitude of hostility with which a large section of the population to-day regard public health administration, particularly quarantine regulations, is a survival of the time when such regulations were productive of much unnecessary cruelty to both the sick and the well. Although the arbitrary exercise of their police powers is still frequently manifest in the acts of public boards of health, there is a growing tendency to apply public health laws with a greater regard for the comforts and feelings of the individual. In the exercise of a wise discretion as opposed to an iron rule there is discernible a recognition of the fact that the willing cooperation of the public is an asset of greater value than all the sanitary statutes put together.

TUMOR TRANSMISSIBILITY BY AN AGENT SEPARABLE FROM THE TUMOR CELLS.

One is getting accustomed in this era of experimental investigation to new and wholly unexpected discoveries. Of this nature is one reported by Peyton Rous in the *Journal of Experimental Medicine,* April 1, 1911, that it is possible to transmit a tumor by means of a filtrate free of the tumor cells. Although former attempts so to produce rat, mouse, and dog tumors have failed, it has been found possible to transmit a so-called sarcoma of a fowl to other susceptible fowls by means of a cell-free filtrate.

The experiments that led to this result were performed with a sarcoma found in the subcutaneous tissue of the head of an adult, pure-bred hen, of the barred Plymouth Rock variety. The tumor material was ground with sterile sand, suspended in Ringer's solution, shaken in a machine, and centrifugalized, and the fluid was passed through a small Berkefeld filter impermeable to *Bacillus prodigiosus.* The filtrate was inoculated into the breasts of young hens of the same species. In one of the experiments, of ten hens thus inoculated, a tumor began to appear in two of the animals as early as eleven days after inoculation, while in eight of the animals tumor nodules were present twenty-eight days after inoculation. These tumors had the same histological structure as the original sarcoma. It was noted that the tumors resulting from the injection of a cell-free filtrate took much longer to appear than those resulting from the inoculation of a bit of tumor tissue. In the latter case the new tumor began to appear within the course of a week, while in the former, following the injection of a filtrate, the new growth appeared in from ten days to three weeks.

In the interpretation of his results, Rous observes that "the first tendency will be to regard the self-perpetuating agent active in this sarcoma of the fowl as a minute parasitic organism. Analogy with several infectious diseases of man and the lower animals, caused by ultramicroscopic organisms, gives support to this view of the findings, and at present work is being directed to its experimental verification. But an agency of another sort is not out of the question. It is conceivable that a chemical stimulant, elaborated by the neoplastic cells, might cause the tumor in another host and bring about in consequence a further production of the same stimulant." For the moment the author has not adopted either hypothesis. He believes "the ultimate significance of these unusual findings can hardly be well discussed until more data are obtained through experiment, especially through carefully devised experiment with the tumors of other species of animals. For it is quite possible that the failure to separate from these growths an agent causing them may be traceable to some interference with the conditions under which this supposititious agent can exist alone, or reproduce the growth in new hosts."

CURE OF OZENA WITH INJECTIONS OF HARD PARAFFIN.

Ozena, as we know it hereabouts, is a multifold and vague condition. Atrophic rhinitis, with its crust formation, its visible atrophy of mucosa, and its occasional fetor, is extremely common, and hardly entitled to be called ozena. The same is true of various forms of sinus disease. True ozena is usually very rare and subjects of it may often be recognized even at a distance by a certain malformation of the nose, which represents a sinking or depression of the organ, which in turn seems allied to some of the effects of destructive disease of the nasal framework. However, syphilis, tuberculosis, and the like are, as a rule, easily excluded; so that true ozena must be recognized as a condition *sui generis,* perhaps due to some congenital fault of development. At a recent meeting of the Laryngological Society of Berlin, Eckstein related a cure of the fetor by injecting paraffin beneath the nasal mucosa (*Berliner klinische Wochenschrift,* February 27). The patient was a girl aged twenty-one, who had had ozena from childhood. The turbinates were in a state of atrophy, and it was believed that a restoration of their contour would improve the condition. Hence a few drops of paraffin were injected beneath the mucosa about every ten days for six months. The improvement was remarkable. Crusts no longer formed and fetor disappeared. The cure was regarded as virtually permanent. The paraffin used had a melting point of about 50° C., and was injected while in the fluid state. The author naively remarks that the girl became betrothed as a consequence of his treatment. B. Frankel, in discussing this report, stated that the idea was old although the technique had been different. Thus one authority incised the mucosa and deposited a layer of paraffin beneath. Rosenberg, who had seen Eckstein's patient, stated that the case was not one of ozena, but of simple atrophic rhinitis. He denied that the mucosa could accommodate so many in-

jections. Frankel made sport of the proof of cure afforded by betrothal. One of the worst patients with nasal and tracheal ozena in his practice secured a husband, but the girl was otherwise a first-rate match. Schoetz had seen benefits in ozenous cases from paraffin injections, but no real cure. Finder had also seen improvement, although the paraffin had soon worked through the mucosa. He ascribed the improvement to the activation of the local secretions. Sobernheim related cures much like those of the lecturer. The paraffin remained *in situ* a long time, and was gradually absorbed. Schoetz reported no resistance in which ozena had been completely cured by massage, which caused the atrophic turbinates to become so hypertrophied that ablation was necessary. Scheier reported many cures during the past six years with paraffin injections, although the remedy was not a specific. Eckstein in closing the discussion insisted on a high melting point, as some of the debaters had used a paraffin which melted much below 50° C. This fact alone would account for untoward effects as well as failures.

LOW BLOOD-PRESSURE.

Dr. W. Edgecombe of Harrogate, England, writes in the *Practitioner* for April on low blood-pressure. He narrates in detail observations made by him extending over a period of two years on a subject aged 40, normal in every respect, but having a persistently low blood-pressure. He also made serial observations on another subject in addition to routine observations on patients.

Edgecombe points out the types of disorders presenting low blood-pressure. These are as follows: (1) Subjects with poor circulation, cold hands and feet, and liable to chilblains. These may gain a temporary rise by means of baths, massage, and exercise, while at the same time the circulation improves, but it is difficult to effect any enduring rise in the general level of the blood-pressure for they are prone on cessation of treatment to relapse to their former state. (2) Cases of pure neurasthenia, having as their prominent characteristic profound fatigue, either somatic or psychic, or both. It is not easy to say whether the low blood-pressure in such cases of neurasthenia is the cause or effect of the extreme fatigue. A rise in blood-pressure is an almost invariable accompaniment of improvement. (3) Tobacco poisoning. Tobacco has the effect of raising the blood-pressure with the apparent anomaly that heavy smokers frequently have a subnormal pressure. (4) In cases of dilated heart, with or without valvular disease, the pressure will sometimes be found low, and a rise in pressure is one of the indications of the progress of the case toward recovery. (5) There are many examples met with of the so-called gouty or rheumatic manifestations of lumbago, sciatica, or neuritis which show a blood-pressure somewhat below the normal. Many of these cases have a subnormal acidity of the urine, and are liable almost constantly to a copious deposit of phosphates, which leads to, or is accompanied by, a state of nervous depression. Edgecombe is of the opinion that the origin of the diminished acidity is digestive and the nervous depression is due to reflex disturbance from irritation of the sensitive nerve-mechanism of the bladder and urethra by the phosphatic urine. He is convinced that some of these cases usually regarded as gouty or rheumatic are neither, but are due to an obscure poison of digestive origin as yet undefined. (6) The clinical symptom phosphaturia, in whatever condition it may occur, is generally accompanied by a low blood-pressure. (7) Young subjects with "rheumatoid arthritis" frequently have a blood-pressure below normal, which rises as the condition improves.

As for treatment Edgecombe points out that it is seldom necessary, were it possible, to raise the blood-pressure to a great extent; a relatively small rise being in most cases coincident with marked amelioration. To effect such a rise, nonmedicinal measures, as diet, exercise, change of air, and hydrotherapeutic procedures, are to be preferred to drug treatment. With regard to diet, an excess of meaty food should be prescribed, with a corresponding diminution of the starchy elements. If, however, drugs are indicated, pituitary extract would seem to have the most powerful and rapid effect. Next in potency would be caffeine, while calcium lactate appears to be moderately effective. Strychnine, according to the writer, is disappointing, and digitalis should be reserved for cardiac cases.

The Treatment of Colitis.

At a meeting of the Chelsea Clinical Society, held on March 14 last, and reported in the *Lancet*, April 1, the treatment of colitis was discussed. Dr. W. Hale White, one of the best known British authorities, maintained that the first point to decide in the treatment of colitis was as to whether the attack was primary or secondary. Colitis might be due to injury or inflammation in a neighboring part, to septic disease or fever, or to Bright's disease. There was also a variety due to the absorption of pneumococci and it might be the result of malignant disease or of appendicitis. If in the latter form it was essential to know whether the appendicitis preceded or followed the colitis. If appendicitis followed not only was appendicectomy useless, but it rendered appendicostomy, the really appropriate treatment, impossible. The important thing in primary colitis was to keep the bowel empty. The question as to treatment by inoculation was debatable. If such treatment were pursued, it should be from a culture of the dominant microbe, which was not always easy to find, and the patient often got well while it was being discovered. Mucomembranous colitis was almost always the result of constipation. Here again the treatment consisted in keeping the bowel empty, and this was best effected by a light peptonized diet and by the administration of castor oil. Regular abdominal massage by a properly trained nurse often did good, but White said that he had never observed any benefit from the employment of electricity. If enteroptosia were present support should be given by suitable stays. Diet did not appear to have any influence. In fact, there were two opposite forms of treatment both equally successful. One consisted in a bulky diet, the other of one which practically left no residue. Opium should be strictly tabooed. Ulcerative colitis

was due to various organisms—*B. coli*, streptococci, and penumococci. A diet of milk and eggs was indicated in such cases and here opium might sometimes be given to relieve pain. Occasionally intestinal antiseptics were useful and very frequently a relapse occurred after vaccine treatment in two or three months' time. In this event appendicostomy should be performed and in severe cases at an early stage. It should also be borne in mind that in these relapsing cases the microorganisms might have got into the blood and that the condition might have become general instead of merely local.

Sexual Education.

One of the live subjects of the day, sexual education, is discussed by J. A. Doléris in *La Gynécologie*, for November, 1910, in a scholarly and interesting way. He deplores the false system of education and morality which has made of reproduction, the highest and holiest of our human functions, a shame and a by-word. He pleads for a proper system of education in sexual matters, begun as soon as the child begins to ask questions about generation and reproduction. For this education we must have competent instructors to teach natural sciences, hygiene, pathology, physiology, and morality. We cannot depend for this instruction on the parent, who too often is almost as ignorant as the child, and is ashamed to impart any instruction to him. The educated woman physician who has been a mother is, in the opinion of the author, the best teacher for the young girl. Questions should be satisfactorily answered as soon as they begin to be asked. By teaching the facts of sexual life in the plant, the bird, and the domestic animals the mind of the child may be gently and easily led to comprehend the facts of fertilization and generation, and when the facts of the human race are told there will be no shock to the mind, but everything will be to him natural, simple, and moral. With the arrival of puberty the young girl should be taught the facts of generation, gestation, and parturition. She should be taught how to receive the approaches of her husband in such a way as to produce healthy offspring, and how to nourish and educate physically her children. The young man should learn that self-control is physiologically possible and normal. The aid to continence derived from physical exercise, manual labor, and abstinence from alcohol and stimulating foods, should be shown him. Continence before marriage, says Doléris, should be inculcated in both sexes. The young must be taught that science and natural law justify this continence, and that sexual indulgence is not necessary to health.

Is New York Proud of Herself?

A writer in the Monthly Bulletin of the New York State Department of Health, March, 1911, asks this question in commenting upon a table reprinted from the twenty-first biennial report of the State Board of Health of California, issued in 1910. The table shows that among the States mentioned New York stands third in per capita wealth and twenty-first in per capita health appropriation; first in total assessed valuation of property and second in total health appropriation. New York's health appropriation is 1.5 mills per $100 of assessed valuation as compared with an average for all the States listed in the table of 8.6 mills. The annual appropriation of Pennsylvania was $1,500,000; that of New York was $152,500; and that of Massachusetts was $140,500. Thus, according to these figures, New York is a very bad second to Pennsylvania. It is a question whether these figures give an accurate idea of the actual amount of money appropriated in the various States for public health purposes. They do not take account of the sums set aside by the various cities for this work. In order to make a just comparison of the expenditures of the different commonwealths for public health purposes, it would be necessary to compile figures giving the total amount of money expended throughout the State, in the various cities and counties, in addition to that expended by the State government. A table such as this would undoubtedly present an entirely different showing. Nevertheless New York, the Empire State, may well look to her laurels when her stalwart neighbor presents such an admirable showing in the appropriation of one and a half millions, which is tenfold that of New York.

News of the Week.

Medical Legislation.—Among the bills reported favorably in the New York Senate on April 21 was that of Senator Loomis establishing in Buffalo a State Cancer Hospital to be managed by the State Commissioner of Health and six other trustees to be appointed by the Governor. The bill appropriates $65,000 for constructing and equipping the hospital on ground adjoining the Gratwick Laboratory at Buffalo, which ground, as well as the present Gratwick Laboratory and land, must be conveyed to the State free of charge. The new institution will continue to be known as the Gratwick Laboratory.

A bill was introduced into the New York Assembly on April 21 providing for the creation of a commission to investigate the prevalence of tuberculosis and methods of prevention, treatment, and cure. The bill appropriates $10,000 for the expenses of the commission, the members of which are to be appointed by the Governor, and it is directed to report to the Legislature by February 1, 1912.

The Bayne antivivisection bill, to the evils of which we referred last week, has been defeated in the New York Senate by the emphatic vote of 34 to 11.

State Medical Examiners.—The New York State Board of Regents has made the following appointments to the State Board of Medical Examiners: Dr. Arthur W. Booth of Elmira to fill the vacancy caused by the death of Dr. Willis G. Macdonald of Albany; Dr. Aaron B. Miller of Syracuse to fill the vacancy caused by the death of Dr. William S. Ely of Rochester, both of these appointments being for terms to expire on July 31, 1912; Dr. Henry B. Minton of Brooklyn; Dr. Floyd S. Farnsworth of Plattsburg, and Dr. Ralph H. Williams of Rochester, for full three-year terms from August 1, 1911. No appointment was made in the place of Dr. William Warren Potter of Buffalo who died recently.

Street Railway Accidents.—Twenty persons were killed on street railroads in New York City during the month of February, three less than in February, 1911. The total number of persons injured during the month was 2,522, of whom 139 were seriously hurt.

Nurses Graduate.—The Margaret Fahnestock Training School for Nurses of the New York Post-Graduate Hospital held its annual commencement exercises on April 18, twenty-nine nurses receiving diplomas for the regular three years' course. The

new addition to the nurses' home, the gift of Mr. Fahnestock, is almost completed, and will be occupied in June. It will provide accommodations for 145 nurses, and will contain also two new classrooms, sitting rooms, and reception rooms, as well as a roof garden.

Christian Science and Contagion.—The Milwaukee Medical Society, at a meeting on April 16, adopted a resolution to the effect that a committee be appointed to investigate the attitude of the Christian Science Church toward the practice of medicine, with special reference to the treatment of contagious diseases. It was explained that there were in one ward of the city alone fifty-three cases of scarlet fever which were being treated only by Christian Scientists, and that many persons were being exposed to the contagion.

Dr. Ewald Found Guilty.—At a meeting of the Board of Censors and the Comitia Minora of the New York County Medical Society held on April 20 a resolution was adopted recommending the expulsion of Dr. Louis Anton Ewald from the society on the charge of falsifying records at the Sydenham Hospital. At the meeting of the Society on April 24, action was taken in accordance with this recommendation, and Dr. Ewald was expelled by a unanimous vote.

Montclair Hospital.—At a joint meeting of the representatives of the Mountainside Hospital Association and the Montclair Homeopathic Society on April 21 action was taken which will permit homeopathic physicians to practise in the wards of the hospital. Heretofore the homeopaths have had the use only of the operating room and the private rooms in the hospital, and plans have been considered for building a homeopathic hospital.

Measles Closes Nursery.—The Eighth Avenue Day Nursery of Newark, N. J., has been temporarily closed because of an epidemic of measles among the children. Up to April 21 eighteen cases of the disease had developed among the forty-eight permanent inmates.

New Toronto Hospital.—The cornerstone of the new hospital in Toronto, Canada, was laid by Lord Grey, Governor-General, on April 11 in the presence of a number of distinguished guests. The buildings, which, when completed, will be the finest structures of the kind in the Dominion, will, it is estimated, cost about $2,600,000. The grounds cover about ten acres in the heart of the city.

Bloomingdale Hospital.—The Board of Governors of the New York Hospital has elected Dr. William L. Russell to be superintendent of this hospital to succeed Dr. Samuel B. Lyon, who will retire July 1, after twenty-five years' service. Dr. Russell is at present superintendent of the Long Island State Hospital, and for a number of years was medical inspector for the New York State Commission in Lunacy.

Gifts to Charities.—By the will of the late Dr. Martin H. Boyce of Coopersburg, Pa., bequests of $12,000 each are made to the ophthalmic and dental departments of the University of Pennsylvania, to St. Luke's Hospital, Bethlehem, and to the Allentown Hospital.

The Hahnemann Hospital of Chicago has received a gift of a plot of land on which to erect its new buildings. The plot, which is valued at $65,000, was given by Mrs. Anna W. Phelps in memory of her husband, Erskine M. Phelps, who was for many years president of the hospital.

The Montefiore Home for Chronic Invalids, New York, has received a gift of $10,000 for the endowment of a ward for the treatment of patients suffering from locomotor ataxia. The gift is made in memory of Adolph Scheftel.

Clinics on Spondylotherapy. — Dr. Albert Abrams announces a series of five clinics on the principles of spondylotherapy, to be given in San Francisco during five days following the session of the American Medical Association at Los Angeles. The clinics will be free to members of the Association. In these clinics will be demonstrated Abrams' methods of diagnosis and there will be an exhibition of patients who have been symptomatically cured of aneurysms (thoracic and abdominal), myocardial affections, pulmonary tuberculosis, and other diseases by simple methods. As the space for the clinics is limited, only those will be admitted who have applied for cards of admission to Dr. Albert Abrams, 246 Powell street, San Francisco, Cal.

The Necessity for Animal Experimentation.—At the recent annual meeting of the American Philosophical Society held at Philadelphia Dr. George W. Crile of Cleveland read a paper entitled "Phylogenetic Association in Relation to the Emotions," in which he pointed out the profound effects on the brain induced by fear and anger. Dr. Alexis Carrel of New York presented a communication entitled "Abnormal Forms of Life and Their Application," in the course of which he illustrated by lantern slides the growth of normal and abnormal tissues in plasma outside the body. In discussing these communications Dr. E. C. Pickering, Director of Harvard Observatory, said "Although not personally interested in these matters, two things have been impressed upon me by these addresses. One is the wonderful progress made in science and the other the necessity of using animals for vivisection purposes. It is the death of either the dog or the man."

Tuberculosis Statistics.—According to the report of the Pennsylvania State Sanatorium for Tuberculosis at Mont Alto, 3,649 cases of tuberculosis were treated in the eighteen months ending December 31, 1910. These included 1,382 cases in a moderately advanced stage of the disease and 1,803 in a far advanced stage. Of 636 moderately advanced cases discharged the disease was arrested in 134, and improvement had taken place in 375. Of 780 far advanced cases discharged, the disease was arrested in 67, and 387 were improved.

Association of American Physicians.—The twenty-sixth annual meeting of this association will be held in the Marborough-Blenheim, Atlantic City, N. J., on May 9 and 10, 1911.

The Northern Medical Association of Philadelphia celebrated its sixty-fifth anniversary on April 11 by a dinner at which Dr. John B. Deaver was the guest of honor. An address of welcome was delivered by the president of the association, Dr. O. L. Latchford. Dr. Thomas Shriner acted as toastmaster, and addresses were made by Dr. Deaver, Dr. David Riesman, Dr. H. C. Paist, Dr. F. X. Dercum, Dr. C. K. Mills, Dr. Austin O'Malley, and others.

The Medical Association of Georgia held its annual meeting at Rome, April 19-21, under the presidency of Dr. Edward C. Davis, Atlanta. The following officers were elected for the ensuing year: *President*, Dr. W. L. Fitts, Carrolton; *First Vice-President*, Dr. R. M. Harbin, Rome; *Second Vice-President*, Dr. T. E. Bradley, Cordele; *Secretary*

and Treasurer, Dr. W. C. Lyle, Augusta; *Delegate to American Medical Association,* Dr. William Doughty, Augusta; *Alternate,* Dr. E. G. Ballenger, Atlanta. Next place of meeting, Augusta.

Rock Island County (Iowa) Medical Society.—At the annual meeting held in Davenport on April 11 the following officers were elected: *President,* Dr. W. L. Eddy of Milan; *Vice-presidents,* Dr. E. Sargent of Moline and Dr. William D. Snively of Rock Island; *Secretary,* Dr. Albert N. Mueller of Rock Island; *Treasurer,* Dr. A. T. Leipold of Moline. The next meeting of the society will be devoted to exercises in memory of the late Dr. G. C. Craig, who was one of its early presidents.

The Cass County (Illinois) Medical Society.—The following officers were elected at the annual meeting held on April 13: *President,* Dr. J. G. Franken of Chandlerville; *Vice-president,* Dr. W. R. Blackburn of Virginia; *Secretary,* Dr. J. A. McGee of Virginia; *Treasurer,* Dr. Charles M. Hubbard of Virginia.

Long Beach (California) Medical Society.—At the annual meeting on April 7 the following officers were elected for the ensuing year: *President,* Dr. W. H. Newman; *Counsellor,* Dr. A. C. Sellery; *Secretary-Treasurer,* Dr. Thomas L. Rogers.

Golden Belt (Kansas) Medical Society.—The following officers were elected at the annual meeting held in Salina on April 4: *President,* Dr. L. S. Steadman of Junction City; *Vice-presidents,* Dr. W. E. Fowler of Brookville and Dr. R. C. Lowman of Kansas City; *Secretary,* Dr. L. O. Nordstrom of Salina; *Treasurer,* Dr. J. W. Neptune of Salina; *Librarian,* Dr. E. E. Hazlett of Abilene.

Northwestern Homeopathic Medical Society.—At the annual meeting held in Rockford, Ill., on April 13 officers for the ensuing year were elected as follows: *President,* Dr. C. A. Walker of Rockford; *Vice-president,* Dr. H. E. Morrison of Freeport; *Secretary,* Dr. Elizabeth Maas of Rockford; *Treasurer,* Dr. F. K. Hill of Rockford.

The East Feliciana Parish (Louisiana) Medical Association met in Clinton on April 5, when the following officers were elected: *President,* Dr. J. W. Lea of Jackson; *Secretary,* Dr. R. P. Jones.

Mississippi State Medical Association.—At the annual meeting held in Jackson on April 12 and 13 the following officers were elected for the ensuing year: *President,* Dr. D. J. Williams of Ellisville; *Vice-presidents,* Dr. J. T. Longino of Jonestown, Dr. S. E. Eason of New Albany, and Dr. J. C. McNair of Fayette; *Secretary,* Dr. E. F. Howard of Vicksburg; *Treasurer,* Dr. L. B. Sparkman of Cleveland.

Tennessee State Medical Association.—The annual election of officers held on April 13 resulted as follows: *President,* Dr. C. J. Broyles of Johnson City; *Vice-presidents,* Dr. J. H. Atlee of Chattanooga, East Tenn.; Dr. W. J. Breeding of Ravenscroft, Middle Tenn., and Dr. J. D. Brewer of Newbern, West Tenn.; *Secretary,* Dr. Perry Bromberg of Nashville; *Treasurer,* Dr. W. C. Bilbro of Murfreesboro. The next meeting will be held in Chattanooga on the second Tuesday in April, 1912.

Tazewell County (Illinois) Medical Society.—At the annual meeting held on April 11 at Pekin the following officers were elected: *President,* Dr. H. V. Bailey of Pekin; *Vice-president,* Dr. H. L. Yoder of Morton; *Secretary-Treasurer,* Dr. E. F. Kelchner of Delavan.

Obituary Notes.—Dr. Thomas P. Scully of Rome, N. Y., a graduate of the Albany Medical College in 1885, a member of the New York State and Oneida County Medical Societies, and attending surgeon to the City Hospital, died at his home of pneumonia after a brief illness on April 19, aged 50 years.

Dr. Elizabeth Mabel Henderson of Hamilton, Ontario, a graduate of the Medical Faculty of Queen's University, Kingston, Ontario, died suddenly at her home on March 26.

Dr. Arthur Case Fitch of Porto Velho, Brazil, a graduate of the Medical Department of Columbian University, Washington, quarantine officer in the service of the Madeira-Mamore Railway, and formerly at St. Elizabeth's Hospital, Washington, died suddenly of cerebral meningitis, on April 9, aged 44 years.

Dr. William E. Wilson of Denver, Col., a graduate of the New York University Medical College in 1853, and a member of the American Medical Association and the Colorado State and Denver County Medical Societies, died after a short illness on April 2, aged 77 years.

Dr. Charles H. Bernstoff of St. Louis, Mo., a graduate of the Humboldt Medical College of St. Louis in 1897, died at the American Hospital of complications following an operation for appendicitis on April 2.

Dr. Leartus Connor of Detroit, Mich., a graduate of the College of Physicians and Surgeons, New York, in 1870, A. B., Williams College, 1865, and A. M., 1868; clinical professor of diseases of the eye and ear in the Detroit Medical College; attending ophthalmological surgeon to the Children's Free Hospital, Detroit, and a member of the American Medical Association, the Michigan State and Wayne County Medical Societies, and the Detroit Eye Club, and an ex-president of the State Medical Society, died suddenly on April 16, aged 68 years.

Dr. Walter H. Muchmore of Brooklyn, N. Y., a graduate of the Medical Department of New York University in 1894, died at his home on April 19, aged 49 years.

Dr. William E. Webb of Unionville, Pa., a graduate of the Jefferson Medical College, Philadelphia, in 1887, consulting physician to the Chester County Hospital for the Insane, died at his home from pneumonia on April 14, aged 48 years.

Dr. Charles A. Oliver of Philadelphia, Pa., a graduate of the Medical Department of the University of Pennsylvania in 1876, and later resident physician in the Philadelphia Hospital; professor of ophthalmology in the Woman's Medical College of Pennsylvania, attending surgeon to the Wills Eye Hospital, ophthalmic surgeon to the Presbyterian Hospital, consulting opthalmologist to the Friends' Asylum and to the State Hospital for the Insane, a member of the American Medical Association, the Pennsylvania State and Philadelphia County Medical Societies, and the American Ophthalmological Society, and a fellow of the College of Physicians of Philadelphia, died at his home of uremia on April 8, aged 56 years.

Dr. Robert L. Hill of Oakland, Cal., a graduate of Rush Medical College, Chicago, in 1864, died at his home of pneumonia on April 6, aged 69 years.

Dr. Frank Anthony of Sterling, Ill., a graduate of Rush Medical College, Chicago, in 1881, a member of the American Medical Association, and the Illinois State and Whiteside County Medical

Societies, and a veteran of the Spanish-American War, died at his home on April 9, aged 53 years.

Dr. Charles S. Elder of Chenoa, Ill., a graduate of Rush Medical College, Chicago, in 1863, and a former mayor of Chenoa, died at his home on April 12, aged 75 years.

Dr. Carl L. Larson of Butte, Mont., a graduate of Rush Medical College, Chicago, in 1902, and a member of the American Medical Association and the Montana State and Silverbow County Medical Societies, died in Chicago on April 7, aged 39 years.

Dr. Lewis B. Craig of Salem, Mo., a graduate of the Missouri Medical College, St. Louis, in 1879, and a member of the American Medical Association and the Missouri State and Dent County Medical Societies, died at his home of pneumonia on April 9.

Dr. Joseph M. Hollingsworth of Mount Airy, N. C., a graduate of the College of Physicians and Surgeons of Baltimore in 1886, and a member of the North Carolina State and Surry County Medical Societies, died suddenly on April 11, aged 43 years.

Correspondence.

SOME SUGGESTIONS CONCERNING THE PRESERVATION AND STERILIZATION OF RUBBER GLOVES AND OTHER RUBBER INSTRUMENTS.

To the Editor of the Medical Record:

Sir:—Even though tactile sensation is lessened and the dexterity of the surgeon somewhat hampered, the routine use of rubber gloves—both for the patient's and the operator's protection—is now conceded, by all experienced surgeons, to be essential to success. This being so, the question of the best means of preserving and sterilizing the gloves becomes important, especially as the constant use of gloves runs into considerable expense. Some surgeons, of extravagant trend, never use a pair of gloves twice; others, bent on economy, try to preserve the glove without endangering its sterility for use on several occasions. After many experiments myself I think I have hit upon a satisfactory technique. The usual method now in vogue of first powdering the gloves and wrapping in a cloth, then sterilizing them, is well enough when attended to by a hospital nurse used to the system, but as any error in the technique may bring about a disastrous result one hesitates to trust all nurses in this matter.

Finding that the large rubber concerns preserve their rubber by keeping it under water, I decided to try this method with my gloves. I selected a very large jar which, after boiling, I filled with sterile water. The gloves were then boiled and immersed in the jar, where they were kept for two months. When examined I found the gloves all right, but a most disgusting odor from the water. In my next experiment, therefore, I added formalin in the proportion of 1 to 10,000. This makes an excellent preservative and there is no smell.

Each time the gloves are used they are tested for punctures. If sound they are boiled for twenty minutes, then immersed in the jar. I find that they last indefinitely preserved in this way, unless punctured during operation. Two pairs that I kept in the solution for a year as an experiment I found to be sterile and perfect in texture at the end of that time. Assuming that my colleagues will find this technique of benefit, I am submitting it for publication.

Jerome M. Lynch, M.D.
58 West Fifty-eighth Street.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

ANKYLOSTOMA.—RHEUMATOID ARTHRITIS AND ORAL DISEASE.—ARTIFICIAL FEEDING OF INFANTS.—INFANTILISM.—EXHIBITIONS.—LORD LISTER.—COLLEGE OF SURGEONS PRIZES.—MEASLES.—OBITUARY.

London, April 7, 1911.

The Milroy Lectures at the Royal College of Physicians were given in March by Dr. Boycott. He took as subject "Ankylostoma Infection." It is important to note the difference between this and the disease, ankylostomosis, because a person may carry the worm in his intestine without suffering the symptoms. Such a one is a "worm carrier," and may spread the disease far and wide, while unconscious of any ill health. That the parasite, the hookworm, was the cause of disease was first established during the construction of the St. Gothard tunnel, though its existence as a parasite of man was known some forty years previously. We now know it to be widely distributed, and in some countries, especially the tropics, it is responsible for a great amount of illness. Indeed, it has been estimated that in some outbreaks it has rendered four-fifths of the population permanent invalids. In America you have a distinct form widely distributed, which was discovered by Dr. C. W. Styles in 1902. Whether its effects differ is for your physicians to determine.

Dr. J. S. Haldane, in 1902, discovered that a skin disease prevailing in Cornish mines, called "bunches" by the workmen, and accompanied by grave anemia and other symptoms of ankylostomiasis, was in reality that disease. Dr. Boycott studied the cases with Dr. Haldane, and they made some interesting observations. They confirmed that of Loos of Cairo, who years before had asserted that the parasite's encapsuled larvæ could penetrate the human skin, and by a roundabout way reach the intestine. Dr. Boycott does not, however, discard the older view of mouth infection, but said he had known this to occur. Infection by the skin, however, assumes a great importance when we remember how the soil is contaminated in some countries by fecal discharges, and these when the disease prevails are laden with the ova of the parasite. It seems certain that the larvæ do not fully develop in the soil, but to attain the adult stage must gain access to the body. The manner in which natives in some parts pollute the soil and go about barefooted may well account for epidemics. As to treatment of the patient Dr. Boycott practically would confine it to thymol, for though three other drugs have been well tried they are inferior, male fern being found useless, eucalyptus, nauseating, and betanaphthol liable to cause nephritis. All four drugs are poisonous if absorbed from the bowel into the economy. But the idea that thymol is very dangerous, he asserted, was not true so long as alcohol, or anything likely to promote absorption, was not taken. But small doses were useless. Half a dram must be given at once if many worms are to be killed, and two or three such doses may be necessary at intervals of one to two hours. The first dose may kill three-fourths, the others diminishing proportions from 30 to 14 per cent. or less. Sodium sulphate should be given concurrently. What is needed is a strong effect of thymol, which

need not last long, but can be repeated in two hours, instead of the older plan of twenty-four hour repetitions.

Mr. Kenneth Goadby detailed in his Hunterian lecture the investigation he has made into the relation of mouth disease to rheumatoid arthritis. A considerable number of animal experiments were made, and he has isolated a streptobacillus, experimenting with which he was able to induce symptoms indistinguishable from osteitis deformans, as well as the changes in joints seen after death. He did not attempt to show that the organism is the etiological factor in all cases of rheumatoid arthritis, infective fibrositis, or other rheumatic ailments, but that in diseases of the jaws, and most especially in rarifying alveolar osteitis, his streptobacillus is present, pure cultivations from which inoculated into or around the knee joints of rabbits have produced symptoms similar to and, in fact, indistinguishable from those of arthritis deformans.

Treating the mouth disease by vaccine proved useful, and a case so treated in a patient suffering from arthritis, as well, was cured of that also. In other such cases the treatment was more or less successful. In all the patients an autogenous vaccine was employed, and the arthritic, as well as the mouth diesase, concurrently improved, and the cases were numerous enough, in the lecturer's opinion, to preclude the explanation of mere coincidence. In the early cases the first inoculation caused increase of the pain and swelling. Reduction of the dose which had been 10,000,000, was therefore tried. Subsequent doses at ten-day intervals were ordinarily increased to 150,000,000 or more. When a tooth was extracted from an infected mouth increase of joint pains might occur, but not if two or three doses of vaccine have been given as a preliminary. The lecturer expressed horror of "that potent predisposing cause of infection of the jaws," ill-fitting, ill-adjusted, ill-conceived, and pernicious crown and bridge work which separates the gum edge, rarely if ever fits closely, but provides a trap for débris of food and invariably promotes "ulceration, periosteal infection, and, sooner or later, rarefying osteitis and suppuration."

Artificial feeding of infants has become so extensively practised—and that in spite of no little opposition by a large section of the profession—that the history of its adoption is worth looking into. Dr. D. Forsyth, brought the subject before the section for children's diseases (R. S. M.) on the 24th ult., tracing the changes from the time of Elizabeth. He said that in the fifteenth century the period of suckling varied between two or three years, a duration still customary among the Japanese and the Greenlanders. In the time of the Stuarts it had declined to between eighteen months and two years. In the time of the Georges it fell to one year, and now he reckoned the average as eight months. The wet nurse, in her palmy days in the eighteenth century, brought many evils, and her disappearance is not to be regretted. Bread and water pap was introduced in the Hanoverian period—a strong prejudice against boiled milk prevailing. This brings us to the nineteenth century, in which the sucking bottle appeared, and was followed by the manufacture of artificial foods. The original feeding bottle was only a cow's horn, to the small end of which were sewn two pieces of leather, as a finger of a glove, and the infant sucked the milk between the stitches. From this have developed the bottles of the present day. The history thus consists of a steady decline of breast feeding under the pressure of improving artificial methods. What, then, of the future? Is Nature to prevail, or man's ingenuity? Dr. Forsyth seemed to think that medical men favored the bottle more than is generally supposed, and he seemed, too, himself, to approve of it, for he spoke of it as nothing more than a practical appreciation of the modern trend of infant feeding.

Some interesting cases were shown at the same meeting, among them two of infantilism; one a boy, aged six, had not grown since he was two. Height, two feet seven inches; weight, twenty-one pounds; intelligence good, teeth carious, genu valgum at five years. Had always drunk large quantities of fluid; at four months as much as four pints a day. Thyroid extract had been given without effect. The other case was in a girl of eight, who had thyroid inadequacy (juvenile myxedema). Height, two feet nine inches; weight, twenty-four and a half pounds. Walked and talked at the usual age. She looked pale and the skin was dry and rather rough. Hair abundant. Mental process rather slow. Thyroid treatment for three months reported to have caused considerable improvement, but no growth.

A tuberculosis exhibition was opened on Tuesday by Princess Louise, Duchess of Argyll. It was arranged by the North Kensington Dispensary for Consumption, and follows on the lines of the exhibition in Whitechapel two years ago. It includes models of rooms, houses, sanatoria, and various appliances for prevention and treatment. It will remain open (free) until the 17th.

Another exhibition is the fourth annual one on nursing, open all this week, in which a wide range of articles directly or indirectly bearing on the work may be seen. Most of them are associated with practice and hospital work, but as an example of "Nature cure," there is a model landscape with arrangements for sleeping out of doors, or for taking air baths (in enclosures). A daily conference was also given, the first by Dr. Dyce Duckworth, who traced the advance made in nursing during his own career. Sir J. Crichton Browne followed on Thursday, and spoke of nursing in lunatic asylums. Sir William Collins has also addressed the meeting. Yesterday Sir F. Chamneys presided, and district nursing was discussed.

Lord Lister has entered his eighty-fifth year, his eighty-fourth birthday being on Wednesday last. He is at present residing at his seaside cottage, and does not often leave his room.

At the Royal College of Surgeons, yesterday, the Walker prize (£100) was awarded to Dr. Bashford for his work on cancer research during the last five years. The committee acknowledged advice and assistance from eminent American, French, German, Italian, and British surgeons and pathologists.

The Cartwright prize (medal and £70) was awarded to Mr. H. P. Pickerel, M.B., L.D.S., professor of dentistry and director of the dental school at the University of Otago, New Zealand

The Jacksonian prize went to Mr. Macfarlane Walker, F.R.C.S., of St. Bartholomew's Hospital.

The Registrar General's report shows that the epidemic of measles is abating. The deaths last week, all of children, numbered 153, as against 182 and 197 in the preceding weeks. There are 914 cases remaining under treatment. The Stepney Board had made the disease notifiable for three months.

On Wednesday the education committee met to

consider a report of their subcommittee. At a late conference of medical officers of health it was held unanimously that children under five years of age should be excluded from the schools. The subcommittee named oppose their opinion, and allege that closure is not likely to influence the course of the outbreak, and add that the notifications show a decline, being for the last four weeks, 3001, 2900, 2197, and 1487, respectively. So they propose no action be taken on the suggestion of the health committee.

Surgeon-General J. A. Marston died on the 31st of March, aged seventy-nine. He was M.D., St. Andrews, 1854; F.R.C.S., 1888; entered the army, 1854; retired, 1889. He was sanitary officer in the Egyptian expedition, 1882, and present at the battle of Tel-el-Kebir. He was mentioned in despatches, received the medal and clasp, the bronze star, and the Order of the Osmanish. In 1887 he was made C.B., and appointed honorary surgeon to Queen Victoria in 1899, an appointment continued by King Edward.

Mr. F. J. Marshall has died at the age of sixty-eight. He has been resident medical officer of St. George's Hospital for thirty years. He took his M.R.C.S. in 1864.

Dr. James Roric has died at Dundee, where for forty-five years he has been medical superintendent of the lunatic asylum. He also lectured in mental diseases at the University College. He graduated at Edinburgh, taking the gold medal, in 1859. He has been a free contributor to medical literature, especially in reference to lunacy legislation and the treatment of the insane. He has been examiner for the Medico-Psychological Association.

Dr. Thomas Murphy, divisional police surgeon, while walking in the street on Tuesday was seen to fall, and was taken to the nearest hospital, where he was found to be dead. He was sixty-three years old, and had been a police surgeon for twenty-four years.

Dr. Alfred Sykes-Ward, surgeon to the Victoria Hospital at Frome, has died at the age of fifty-five. He was M.D., Ed., 1889.

Mr. W. D. P. Swain, J.P. for Yorkshire, has died at the age of eighty-two. He qualified, M.R.C.S., in 1850.

Surgeon-Lt.-Col. A. B. Robinson, whose death has occurred at the age of seventy from cardiac failure, entered the army medical service in 1864 as a licentiate of the two royal Irish colleges and retired in 1885.

OUR CANADIAN LETTER.

(From Our Special Correspondent.)

REPORT OF ROYAL COMMISSION ON TUBERCULOSIS IN QUEBEC—COCAINE IN QUEBEC—MEETING OF THE CANADIAN MEDICAL ASSOCIATION IN MONTREAL—RODDICK BILL—POLIOMYELITIS IN CANADA—ONTARIO MILK BILL—PURE WATER BILL FOR CANADA—OPIUM BILL INTRODUCED INTO CANADIAN HOUSE OF COMMONS—CANADIAN ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS—REPORT ON THE PREVALENCE OF SMALLPOX IN MONTREAL—WILL OF THE LATE CHARLES BYRD—PROHIBITING THE SALE OF MORPHINE IN BRITISH COLUMBIA—EXTENDED COURSE OF STUDY AT MCGILL UNIVERSITY—PUBLIC HEALTH EXHIBIT FOR THE NEXT CANADIAN NATIONAL EXHIBITION—SMALLPOX IN OTTAWA—LAYING THE FOUNDATION STONE OF THE NEW TORONTO GENERAL HOSPITAL—BILL INTRODUCED INTO ONTARIO LEGISLATURE TO PROVIDE SPECIAL CLASSES FOR MENTALLY DEFECTIVE CHILDREN AND FOR MEDICAL INSPECTION—DISEASES IN ONTARIO DURING MARCH—SCARLET FEVER IN TORONTO—INADEQUATE ACCOMMODATION IN TORONTO — ISOLATION HOSPITAL — PROPOSED DENTAL CLINICS FOR POOR OF TORONTO—OTTAWA'S WATER SCHEME—TUBERCULOSIS IN ONTARIO—CONDITION OF THROATS AND EYES IN TORONTO SCHOOLS—SUGGESTED HOSPITAL FEDERATION FOR TORONTO—ABOLITION OF THE COMMON DRINKING CUP—CONTAGION IN BOOKS—VACCINATION OF CHILDREN IN VANCOUVER.

Toronto, April 15, 1911.

The Royal Commission on Tuberculosis appointed to inquire into the prevalence of the disease in Quebec has presented its report recently. The death rate from tuberculosis in Quebec remains stationary and it is therefore urged that a vigorous antituberculosis campaign, both educational and preventive, be initiated at once. The new regulations with regard to the sale of cocaine in the Province of Quebec provide that the drug cannot be sold in any form without a physician's prescription. The attendance at the forthcoming meeting of the Canadian Medical Association, to take place in Montreal on June 7, 8, and 9, is expected to be large. Sir James Barr of Liverpool, almost the greatest authority in England on heart disease and a racy and humorous speaker, will deliver the address in medicine. The address in surgery will be given by Dr. Primrose of Toronto, while Dr. W. J. Mayo of Rochester, Minn., will read a paper on "Gall Stone Diseases." Dr. Casey A. Wood of Chicago will read a paper before the ophthalmological section. The Roddick bill, reference to which has been made in a former letter and which provides for one registration and establishes a Dominion Council, upon whose license physicians may practise in any province, passed a special committee of the Canadian House of Commons on March 3.

Efforts are being made by the Public Health Committee of the Canadian Commission of Conservation to acquire more definite details with regard to the prevalance of poliomyelitis in Canada. With this object in view circulars are being sent to physicians throughout the dominion requesting information as to cases of this disease which have come under their notice between November 1, 1909, and October 31, 1910. A Milk Bill has been passed by the Ontario Government to regulate the standard and sale of milk. The bill provides that in fixing a standard for milk much discretion is left with the municipalities. An endeavor has been made recently to introduce into the Canadian House of Commons a bill the object of which is to compel municipalities to supply pure water for drinking purposes. The provisions of the bill are to the effect that any municipality which takes water for people's use from a river, or stream, or running water into which sewage is discharged without properly treating the water and sterilizing it, shall be liable to a fine of $200. Mr. Mackenzie King has brought a bill into the Canadian House of Commons to restrain the sale of opium. The Canadian Association for the Prevention of Tuberculosis will hold its annual meeting on May 18 and 19, in London, Ont. Dr. J. E. Laberge, chief of the civic contagious branch of the Board of Health of Montreal, a short time ago submitted a report on the prevalence of smallpox and the neglect of vaccination. The controllers of Montreal have taken cognizance of the matter and have decided to rigidly enforce the by-law calling for the vaccination of all school children

and employees engaged in manufacturing and in other industrial establishments in that city.

The late Charles Byrd, Montreal, left $10,000 to Montreal General Hospital, $5,000 to the Protestant Hospital for the Insane at Verdeen, $2,500 to the Western Hospital, and $2,000 to the Alexander Hospital. The British Columbia Pharmaceutical Association is the first society of a similar kind in America to prohibit the sale of morphine, cocaine, and liquor, and medicine containing the same, without the order of a physician. The medical faculty of McGill University has announced that an extended course of study for graduate students will be given during the coming summer. Commencing on Monday, June 12, the course will be continued for a period of six weeks, during the first half of which the work will be conducted in the Montreal General, and during the second half in the Royal Victoria Hospital. According to an announcement made by Dr. John W. S. McCullough, chief health officer of Ontario, a public health exhibit under the auspices of the Provincial Board of Health of Ontario will be a feature of the next Canadian National Exhibition. The exhibit will consist of public health equipment of every kind and will also include a varied assortment of apparatus, etc., relating to the prevention of disease. The existence and spread of smallpox in Ottawa has occasioned a considerable amount of alarm amongst its inhabitants. On April 4 the mayor wired to the Ontario Board of Health requesting that immediate action be taken.

The Board of Control of Ottawa, it was thought at the time, would probably authorize Dr. Hodgetts, medical adviser to the Dominion Conservation Commission, to take charge of the city health department. On April 4 there were twenty-five cases of smallpox at Porter's Island Hospital, Ottawa. On April 4 Earl Grey, Governor-General of Canada, laid the foundation stone of the new General Hospital, Toronto. The proceedings were characterized by a good deal of ceremony. Mr. J. W. Flavelle, chairman of the board of trustees, introduced the speakers and gave a brief sketch of the preliminary work in connection with the new building. He described how the site comprised a little over ten acres facing College street, and in proximity to the University of Toronto. He said that there was already under contract $1,400,000 worth of buildings, and when further contracts were let the expenditure would be brought to $2,000,000. The site cost $600,000, so that the total expense would be $2,600,000. The University of Toronto had made a grant of $600,000; $400,000 had come from the city of Toronto, and $1,000,000 more had been contributed by private citizens. Consequently, $600,000 was still needed in order that the institution when completed might be free from debt. Dr. Pyne, Minister of Education for Ontario, introduced a bill in the middle of March providing for the establishment and maintenance of special classes for children mentally defective, and for the medical inspection and treatment of the health of those children. The bill specifies that such classes may be formed for those "who are backward or abnormally slow in learning," and "who, from physical or mental causes, require special training and education." Provision for medical inspection is made as follows: "The board may provide for medical inspection by a duly qualified medical practitioner of the children attending special classes, and, upon the recommendation of the medical inspector, may provide for medical treatment being given to any child who appears to the medical inspector to require the same, and whose parents are unable from poverty or other cause to provide adequately for the treatment of the child. It shall be the duty of a board, which has established special classes under the act, to provide for the proper supervision of the health and treatment of every child attending a special class, and for this purpose to direct the medical inspector, or such officer as the board may appoint, to visit the children in their homes and to consult and advise with the parents of the children as to their treatment in their homes, and the conditions which will best enable the children to attain a normal degree of intelligence and education." Subject to the approval of the Minister of Education, the board may provide a special course of study for children attending the special classes. Grants shall be annually apportioned among the special classes by the Minister.

In Ontario during March scarlet fever has been unusually prevalent. Out of 707 cases there were 24 deaths, as compared with 357 cases and 20 deaths in March of last year. According to Dr. McCullough, chief medical officer of the Provincial Board of Health, the disease has been of a mild type. Dr. McCullough at the beginning of April issued a statement showing that there had been 1,763 cases of contagious disease in Ontario during March, 201 of which were fatal. Seven cases of cerebrospinal meningitis were reported in the course of the month, all of which proved fatal. Of three cases of poliomyelitis, one resulted fatally. Smallpox showed a marked decrease, with 52 cases and one death, as compared with 81 cases and no deaths in March of last year. Typhoid fever cases numbered 300, with 41 deaths, as compared with 162 cases and 54 deaths for the corresponding month of 1910. There had been 176 cases of diphtheria, with 24 deaths; 369 cases of measles, with 8 deaths; 127 cases of tuberculosis, with 91 deaths, and 22 cases of whooping cough, with 4 deaths. In March 441 cases of scarlet fever occurred in Toronto, and Dr. Charles Hastings, medical officer of health for the city, attributed the large number to the inability to take care of such cases in the isolation hospital.

The proposition to establish dental clinics for the poor of Toronto was made on April 4 to the subcommittee on medical inspection of the Board of Education, by representatives of the following organizations Academy of Medicine, Board of Education, Dental Association, Local Council of Women, Children's Aid Society, Associated Charities, Board of Trade, and Trades and Labor Council. Those who advocate the proposition desire the establishment of at least four clinics.

Canadian press despatch, March 15, states that a progress report on Ottawa River storage, submitted to the Minister of Public Works by C. R. Coultee, the engineer in charge, shows that storage so far in sight, and for which controlling dams are either under construction or sites fully surveyed and contract plans under way, will have a most beneficial effect on the water of the river, both as to its flow at certain seasons and its suitability for drinking purposes. "Taking the low period at 150 days between October and March," says the report, "it will be possible to augment ultimately the low water flow at Ottawa for that period by 10,000 or 12,000 cubic feet per second."

Dr. R. W. Bruce Smith, in his report on the hospitals and charities of Ontario, issued recently, says: "Tuberculosis is recognized as the most frequent

cause of death in Canada; no other single disease approaches it." Still the disease is steadily decreasing in Ontario, evidently due to the fact that people are beginning to learn how to live rationally. Dr. Smith is a great believer in the good effects of education, and says: "If people were educated, not frightened, in regard to tuberculosis a more rational view would be taken, and the steps necessary for its cure and prevention would be better understood. The result would be seen in the disease being gradually but certainly exterminated from Ontario." "There should be in at least twenty hospital centres of Ontario a public dispensary, established and worked on the lines similar to those adopted in Toronto and Ottawa, and similar to those under the direction of the Health Associations in Hamilton and London." Every city, in Dr. Smith's opinion, needs a convalescent home, but there is only one institution of this description in Ontario.

Condition of children's throats and eyes in Toronto is very unsatisfactory. The reports on medical inspection in the city schools have just been submitted to the management committee of the Board of Education by Dr. Struthers, chief medical inspector, and Miss Lina Rogers, superintendent of nurses. Enlarged tonsils were found in 1,387 children, and eye affections in 1,203, while 420 were found to have bad teeth. The total number of children examined was 2,897.

According to the *Toronto Evening Telegram*, March 24, a scheme of federation under which the policy of all the regular hospitals in the city, and the purchasing of supplies for these hospitals by one purchasing agent, to be controlled by a central board, is said to be so far advanced that the scheme will be laid before the City Council at an early date. It is said to be no part of the scheme to deprive each hospital of its local management, but merely to prevent overlapping in different lines.

The by-law suggested to abolish the use of the public drinking cup in Ontario provides that it shall be unlawful to provide a public drinking cup in the city in any public school, hotel, theatre, public hall, public park, streets or ways, or any premises used as a public institution, the same to be substituted by a sanitary fountain or individual drinking cups. Dr. Hastings, the medical officer of health of Toronto, however, stated that he had discovered that a by-law was not necessary to abolish the evil, that he had found that he possessed, under the Medical Health Act, the necessary authority to take proceedings to do away with it.

It has been resolved at a meeting of the management committee of the Board of Education of Toronto that in order to protect the school children from the danger of contagious diseases new scholars, or scholars promoted to another class, be given a new set of books, which shall become the property of the pupil; if these are ordered destroyed by the medical health officer on account of contagious disease they shall be replaced by a set supplied by the Board of Education.

A resolution has been passed by the South Vancouver School Trustees that children are not to be vaccinated without first obtaining the consent of the parents.

Individual Isolation in General Wards.—Lesage describes in detail the system of isolation practised at the Hérold Hospital. Each bed is in an individual closed compartment. This obviates the necessity of separate pavilions for infectious cases.—*Bulletin de la Société de Pédiatrie de Paris.*

Progress of Medical Science.

Boston Medical and Surgical Journal.

April 13, 1911.

An Analysis of Forty-six Cases of Prostatectomy. L. Davis.
Vaccines in Puerperal Sepsis. W. H. Watters and C. A. Eaton.
Intrathoracic Insufflation Anesthesia: Apparatus and Cases. A. Ehrenfried.
The Extirpation of the Tonsil by Enucleation: Partly Instrumental, Partly by the Use of the Finger. L. M. Freedman.
Late Cesarean Section; Report of a Case. S. Rushmore.

Prostatectomy.—L. Davis states that the suprapubic enucleation has its strong points; it is a quick method, and easy of performance, except when the gland is small, fibrous and adherent, when it may be impossible, as admitted even by Freyer. The end results are excellent; if the patient survives the operation, he is almost sure of a good functional result. There is little danger of injury to the rectum or of incontinence, the bugbears of the perineal route; sexual power is often retained, although the ejaculatory ducts are seldom spared. On the other hand, there is considerable shock, and often hemorrhage, which is difficult to control; also liability to sepsis and urinary infiltration. The chief advantages of the open perineal method are that the operation can be done under the control of the eye, shock is markedly less, hemorrhage can be more effectively controlled, sepsis is usually inconsequential, fibrous or adherent prostates can be removed by morcellement. Sexual power can be preserved in a fair proportion of cases. The convalescence is quicker and more comfortable; the functional results are as good in the hands of the elect.

Vaccines in Puerperal Sepsis.—W. H. Watters and C. A. Eaton report a series of fifty cases of puerperal sepsis in which polyvalent vaccines were used. No claim is made that the vaccines should replace other generally recognized methods. On the contrary, they should be used to assist all others that have proved to be of value. Unfortunately, such procedures of proven value are as yet only too few. In the series reported a hot vaginal douche was usually employed; very rarely, in only one or two cases, an intrauterine douche. Curettage was not performed in any instance. The bowels were maintained in an active condition and remedies were used when indicated. The authors strongly advise leaving the patient as free from manipulation or local treatment as possible and believe that the results well bear out these instructions. They prefer to draw no conclusions concerning the results of the treatment as a whole, as they realize that the ground is still debatable. Two facts are given in conclusion: One is that no demonstrable harm was done to any person; the other, that patients showed much improvement after the inoculations and recovered when even the best clinicians foretold a fatal termination.

Insufflation Anesthesia.—A. Ehrenfried describes the apparatus that he has devised for the application of intrathoracic insufflation anesthesia. This form of anesthesia has a wide scope of application outside of the field for which it was originally designed. In operations upon the face, mouth, and neck it has obvious advantages. The operating field is unobstructed. Run at a low pressure, it will insure adequate ventilation of the lungs and obviate the possibility of aspiration of mucus or blood and thus lessen the frequency of secondary pneumonia following face and mouth operations in the elderly.

Enucleation of Tonsil.—L. M. Freedman describes his operation of extirpating the tonsil by enucleation, partly instrumental and partly by the use of the fingers. The steps of this operation are as follows: Separation of the anterior pillar; incision into the supratonsillar fossa; finger dissection of the tonsil anteriorly and posteriorly; snare engaged over the tonsil and tightened; and handle of the snare turned and tonsil gradually excised.

Late Cesarean Section.—S. Rushmore reports a case

of this operation which is of interest because of the gratifying result after fifteen hours of labor, three with membranes ruptured, when delivery with forceps on the floating head had been attempted in vain.

The Importance of Nasal Breathing. A. E. Schmitt.
The Rôle of Acute Bronchitis, Exacerbations, and Remissions in Pulmonary Tuberculosis. H. J. Hartz.

Rectal Constipation and Obstipation.—S. G. Gant calls attention to the following types of constipation which are not generally recognized, although they are fairly common and easily corrected: 1. Hypertrophied O'Beirne's sphincter. 2. Hypertrophied rectal (Houston's) valves. 3. Hypertrophied levatores ani muscles. 4. Hypertrophied sphincter muscle. 5. Coccygeal deviation. 6. Foreign bodies. 7. Atonic rectal constipation.

Leprosy.—By H. Fox. See MEDICAL RECORD, January 28, 1911, page 177.

The School Nurse.—S. W. Newmayer states that the school nurse has opened a path to the development of an ideal system of betterment of public health in our cities. The school nurse of the future will be the Municipal Nurse, whose duties will include not only protecting the health of the school children but also caring for infants, teaching mothers their hygiene and proper feeding, thereby reducing this great and unnecessary mortality. By improving housing and living conditions she will reduce the mortality from tuberculosis. She will be the supervisor of health and sanitation in the factories, as well as a teacher of hygiene to the children at school and to their parents at home. She will be the connecting link between the destitute family and the numerous organizations dispensing aid. With a small district assigned to a nurse, and she being held responsible for the health of every person and sanitation of every house in that district, results will be obtained which would be impossible by any other system. The school nurses of the future are destined to be the guardians of public health.

Polioencephalitis.—I. D. Steinhardt discusses the clinical picture of poliomyelitis under this name.

Syphilis Followed by Paresis.—C. Pope reports a case of cerebrospinal syphilis followed by paresis. He states that syphilis in this domain of the human economy is so regularly irregular, that irregularity of symptoms, the absence of system, constitutes a valuable diagnostic point. When one runs across a strange mixture of psychic and somatic symptoms, a mélange of no type, bizarre, unsystematized, transient, appearing, disappearing, recurring, seemingly sudden changes, better now, worse again, this should lead the diagnostician to an inquiry and investigation, including a serodiagnosis. One must remember that nervous syphilis follows no law, no rule, that it is as inconsistent and fickle as femininity itself. Especially does this apply to the mental symptoms, which are in these cases to be interpreted by the somatic state. A group of mental symptoms, in conjunction with well marked physical ones, reads differently than when they stand alone.

Functional Nervous Diseases.—G. E. Price discusses the etiology of hysteria, neurasthenia, and hypochondria, noting that these have in common many predisposing and exciting causes.

Duodenal Ulcer.—J. M. Lynch notes that the two conditions which are most apt to be confounded are spasm of the pylorus, due to chronic appendicitis, and duodenal ulcer, with all the symptoms referred to the appendix. A carefully taken history will clear up the diagnosis, as every case of duodenal ulcer has a clear-cut history.

Importance of Nasal Breathing.—A. E. Schmitt states that mouth breathing in most instances is purely a habit. In the case of nasal obstruction the amount of air possible to be drawn through the nose may be entirely inadequate, and mouth breathing becomes a necessity until the obstruction is removed. In other cases it occurs in conditions in which the muscle tonus has been lowered in various parts of the body, resulting in relaxed and flabby muscles and ligaments. When this occurs in muscles supporting the lower jaw (the temporals, masseters, and pterygoids) the jaw drops and mouth breathing occurs and becomes a habit. The relaxed lower jaw muscles remain shortened, the reduced traction on the bone itself producing the small mandible and receding chin. The drawn skin of the cheeks, produced by the dropping of the jaw, presses on the superior alveolar process, and this, added to the vaulted palate, is a second factor, producing the contracted alveolar process and irregularity of the teeth.

Bronchitis in Tuberculosis.—H. J. Hartz notes that of a series of fifteen cases, presenting themselves with vague symptoms of colds, bronchitis, pleurisies, stomach trouble, or muscular pains, six proved to be cases of tuberculosis in the incipient stage, while four patients were tuberculous for months prior to their coming under observation. In the latter the progress of the disease was extremely slow and exacerbations and remissions were so mild and infrequent as to give the patient no cause for alarm. The symptoms in most cases were transient in character, incapacitating the patient but for a brief duration of time, yet were frequent enough to oblige the patient to seek medical relief. These transient exacerbations are of great importance both to the physician and patient, since they give the patient a false sense of security upon being told that he or she is suffering only from a cold when in fact the underlying lesion is tuberculous in character.

Chronic Pancreatitis.—J. B. Deaver presents a description of this condition based on a study of thirty-eight cases. The leading and most constant symptom is pain, but it is often absent or inconspicuous and is not itself characteristic. It varies from dull discomfort or ache to lancinating or colicky pain quite like gallstones. In this latter case the gall-bladder is usually diseased and the author is inclined to interpret colic as indicative of involvement of the bile passages. No definite relation to diet was found in his thirty-eight cases, which seems in a measure to differentiate the trouble from gastric or duodenal ulcer of gall-bladder disease. Nausea and vomit-

ing are only slightly less frequent than pain and in ten of his cases preceded the pain. The third important symptom is jaundice, which was altogether absent in only fourteen. It may come on painlessly and may be continuous. When associated with rapid wasting and loss of strength it simulates malignant disease of the head of the pancreas. The combination of intermittent jaundice, pain, and febrile attacks may also be perfectly characteristic of Charcot's hepatic intermittent fever. The author has diagnosed stone in the common duct in such cases. The degree of jaundice may vary from the slightest tinge to the black jaundice of the older writers. General symptoms are usually well marked. When the function of the organ is seriously disturbed there is always loss of weight, but loss of appetite is not by any means constant, though the loss of weight may sometimes be due to decreased intake of food. Second, it is due to malassimilation of the imperfectly digested food, and sometimes to the biliary intoxication and, more rarely, to the absorption of the bacterial products. In most cases fever was known to have been present, but it is not such a prominent symptom in chronic pancreatitis as figures would seem to show. It is present only during exacerbations and, as a rule, the temperature is normal.

Intestinal Bacteriology.—A. I. Kendall states that fermentation takes precedence over putrefaction; that is, carbohydrate shields or spares protein from bacterial attack. The same generally holds in the metabolism of the human body; carbohydrate spares protein. Toxic substances are not formed to any extent in media containing more than minimal amounts of utilizable carbohydrate, so long as there is enough carbohydrate for the bacteria to act on. When one remembers that bacterial toxins are, so far as is known at present, associated with the breakdown of protein, the significance of this shielding action of carbohydrate for protein becomes apparent. In cases referred to as endogenous infections, that is, in which there is an overgrowth of bacteria of intestinal origin, the most noticeable, or at least most common, pathological result is the slow absorption of putrefactive products which not infrequently are the result of a too liberal protein diet.

Vaccines in Otitis Media.—P. G. Weston and J. A. Kolmer presented the following tentative conclusions: the best time, all things considered, for commencing vaccine treatment in cases of otitis media is from the eighth to the sixteenth day of the discharge. Continued high fever, nephritis, toxemia, and various intercurrent affections are contraindications to the administration of vaccines. Under vaccine treatment three times as many patients are cured within thirty days and permitted to go home as under the usual treatment. This means that the average residence of a patient in the hospital has been considerably decreased. In general, cases of otitis media offer a fruitful and encouraging field for the employment of vaccine therapy.

Multiple Myeloma.—J. M. King states that in this condition the chief clinical symptoms are pain referred to the bones, often with later formation of palpable or visible tumors, cachexia, and the presence of Bence-Jones albumose in the urine. In some cases pain is absent. Leucocytosis is not common. The Bence-Jones albumose is virtually diagnostic though not invariably present. It usually occurs early and persists throughout, though there may be remissions. The amount of urine is usually increased, often slightly cloudy, pale in color, neutral or slightly acid, with specific gravity ranging from 1.004 to 1.012. It is often mistaken for ordinary albuminous urine, but when heated is found to become cloudy at from 50 to 60° C., the turbidity disappearing with the addition of acetic acid or by heating to the boiling point, to show again on cooling. There is usually a biuret reaction. The diagnosis may be difficult if the Bence-Jones body is absent.

Emergency Culture Medium.—I. M. Wood recommends the use of normal salt solution with material from the site of the infection as a culture medium for the cultivation of bacteria in the preparation of bacterial vaccines. He finds that a number of these will survive and grow in such media. There are some exceptions; pneumococci can be kept alive in it only a very short time and streptococci do not grow well unless serum from the site of the infection be added, but this can easily be done. Staphylococci, *Bacillus typhosus, B. coli, B. pyocyaneus,* and acne bacillus can be readily grown.

Systemic Blastomycosis.—R. G. Washburn states that the characteristic skin lesions in this condition are usually easily recognized while the diagnosis can be confirmed by the finding of the blastomycetes. He reports a case of systemic infection in which, in spite of repeated search made for it, the sputum contained no blastomycetes. Otherwise the case resembles closely the majority of those so far recorded. The prognosis in these systemic cases is exceedingly unfavorable, only four recoveries having been reported, and the treatment may be considered rather unsatisfactory. The only drug having any apparent specific action on the disease is the iodide of potassium. All the recovered patients have received it in large doses. Locally the lesions should be treated like those of the purely cutaneous form of the disease. One of the best local applications is 1 per cent. copper sulphate solution in conjunction with the use of the *x*-ray.

Tonsil Snare.—W. D. Black has devised an improved instrument of this kind.

Proctoclysis.—J. E. Cannaday states that he has found the most simple method of inducing the fluid to flow drop by drop is an ordinary wire hairpin, straddling the rubber tube and with the free ends twisted together. Three or four wooden toothpicks or a match trimmed down to a wedge-shaped point are pushed in between the hairpin and the tube till the flow becomes just as desired. A steady drop-by-drop flow can be provided for as long as needed. A soft rubber catheter in the rectum, made after the type of the usual retention catheter or secured by sticking plaster, is much less irritating than a hard nozzle.

Venereal Prophylaxis.—R. E. Ledbetter, from an experience of several years has found that treatment within twelve hours after exposure makes the danger practically *nil.* After twelve hours it often fails. The use of 33⅓ per cent. calomel ointment appears to be of special value in syphilitic exposures, and an absolute preventive if employed early and thoroughly.

Furunculosis.—H. K. Gaskill states that furunculosis showing no causative factor in any kidney complication, can be successfully treated by being opened with a sharpened cotton applicator dipped in phenol, with injections of polyvalent staphylococcus vaccines and applications of salicylic acid ointment from 8 to 15 per cent. strength. The inability of the physician to prepare autogenous vaccines on account of lack of time, laboratory facilities, and experience makes the stock vaccines prepared by reliable firms a much more desirable method of procedure in the average case. The pain on opening a furuncle is much less than with a knife, as phenol is slightly anesthetic. The reaction is very slight after the first injection and is lessened by use of the dry cup. It is not necessary to record the index, and the dose may be regulated by the clinical manifestations.

Epidemic of Typhoid Fever.—J. P. Simonds reports an epidemic in which the typhoid and colon bacilli were isolated from the spring water used for drinking purposes.

Typhoid Vaccine.—J. P. Fletcher presents abstracts of fourteen cases giving the Widal reaction, in some of

which the effects of the vaccine were very striking. In all the cases the general condition was improved, and in none of them were there any bad results caused or any increase of the patient's discomfort.

Dysmenorrhea.—M. L. Harris describes his method of treatment of certain forms of dysmenorrhea due to abnormal conditions of the ovaries and tubes. The method consists in resection of the nerves supplying the ovary and the internal three-quarters of the tube, especially those of the spermatic plexus. The effect of the resection is to cause anesthesia of the ovaries and inner portion of the tube. Of course, this operation does not relieve other forms of dysmenorrhea than those attributable to these nerves. He has operated now on over twenty women with gratifying results, and no other effect than the relief of pain has been noted, as the sexual and reproductive functions are not disturbed.

Testing Visual Fields for Color.—T. A. Williams describes a convenient method of testing the visual fields for color without the use of a perimeter.

Heart Failure.—By J. Mackenzie. Will be noticed later.

Total Enucleation of the Prostate.—P. J. Freyer adds to his series of 600 cases already reported a recent series of 300 cases of this operation. There were 9 deaths, or 4.5 per cent.

Treatment of Pulmonary Tuberculosis with Bovine Tuberculin.—N. Raw concludes on the basis of an experience of 300 cases that injections of bovine tuberculin are of the greatest value, especially in early cases in which the deposit of tubercle is localized, as in one apex, or in a lymph gland or single joint, but where the tuberculosis is disseminated and complicated by secondary infections the use of tuberculin cannot be expected to be of much avail.

Acute Inflammation of the Thyroid.—W. S. Robertson notes that this condition comprises two forms; acute thyroiditis, in which a previously healthy gland is attacked; and acute strumitis, in which the gland is already goitrous. The disease may occur as an epidemic, is more common in men, and trauma, congestion, and exposure to cold have been looked on as predisposing conditions, but the condition arises either in an already goitrous gland or as a complication in the course of an infectious disease. The cases terminate by resolution, or go on to suppuration and even gangrene. The thyroiditis associated with mumps and influenza has never been observed to suppurate; all the malarial cases of which the author has records, and all the cases connected with acute rheumatism, tonsillitis, erythema nodosum, and other rheumatic affections, ended in the same way. On the other hand, in all the pneumonic and puerperal cases and in a very large majority of the typhoid, diphtheria, and erysipelas cases the inflammation went on to suppuration.

Law and the Prevention of Drug Abuses.—D. W. Gadd discusses the present state of the law with regard to the prevention of drug abuses.

Bullet Wound of the Skull.—W. L. Harnett reports a case in which the bullet had entered through the squamous portion of the temporal bone, passed vertically downward between the bone and the dura mater, and finally lodged in the petrous portion of the temporal, with the posterior end in the temporo-sphenoidal fossa, the body wedged in the tympanum almost vertically, and the point protruding into the glenoid fossa.

The Eye of Surgical Needles.—J. L. Thomas describes a surgical needle which he has devised, in which the part played by the thread in the process of threading is absolutely passive, which is a reversal of the part taken by the thread in the ordinary course of threading the needle. The eye possesses a side entrance with a spring grip.

The Curative Effect of Salvarsan Serum in a Case of Syphilis. C. Gibbs and E. S. Calthrop.

Heart Failure.—By J. Mackenzie. To be noticed later.

Antivivisectionists and the Research Defence Society.—Professor Schäfer states that it is mainly the ignorant and ill-informed members of the community who support the antivivisection agitation. It receives little encouragement from the educated classes. But ignorance will always be in the majority, and, unless one takes means to dispel it serious impediments may be imposed on the future progress of medicine. To prevent this the purpose of the Research Defence Society is to advance the knowledge of the functions of the animal body both in health and in sickness—a knowledge which alone can render it possible to alleviate the sufferings, not only of man, but also of the creatures which are dependent upon him and of which he is entitled to make use for his subsistence and comfort.

Melancholia.—G. M. Robertson discusses certain medicolegal and practical considerations relating to melancholia. Mental diseases are divided into two groups. First, those which are not accompanied by any loss of the power of self-control or disorder of conduct, such as, for example, a slight failure of memory. The diseases of this group are purely medical and personal. In the second group are those diseases in which there is loss of the power of self-control with disorder of conduct, and therefore these conditions are of legal as well as medical interest. The term "insanity" or "lunacy" may be applied to all these.

Etiology of Iritis.—T. H. Butler, as the result of an analysis of 100 cases of iritis, notes that in at least 30 per cent. of all cases it is almost impossible to determine the real origin of the disease. Twenty-five per cent. are due to syphilis, and only about 5 or 6 per cent. can truly be termed rheumatic. An examination of the figures shows that in 22 syphilitic cases 10 were monolateral and 12 bilateral, so that this question cannot be considered in coming to a diagnosis. Cases due to oral sepsis and to intestinal stasis are more frequently bilateral than syphilitic cases. One patient put down as rheumatic iritis had had an acute attack of rheumatic fever only five weeks before the iritis came on. Two cases were associated with albuminuria. In one there were albuminuria, iritis, and a single retinal hemorrhage, but no retinitis. The other was a case of albuminuria and general anasarca.

Affections of the Eyes.—H. P. Bennett discusses a few practical points in relation to some common affections of the eyes.

Mechanical Etiology of Optic Neuritis.—M. Mamourian and C. J. Smith advance the contention that arrest of, or marked interference with, the cerebral venous return (with consequent subnormal cerebrospinal fluid absorp-

tion) is the predominant factor in producing increased intracranial pressure, and that papilledema is due to the resulting rise of fluid pressure in the optic nerve sheath. Given a condition of inhibition of the process of absorption, the pressure in the subarachnoid space will increase, the authors assert, either in consequence of continued secretion of the cerebrospinal fluid or else as a result of the diminution in the size of the cerebrocranial space.

Salvarsan Serum.—C. Gibbs and E. S. Calthrop report the curative effect in a case of syphilis of the injection of 10 c.c. of a serum obtained from cantharides blister on the abdomen of another syphilitic patient who four days previously had had an intravenous injection of 0.4 gram of salvarsan.

Berliner klinische Wochenschrift.

April 3, 1911.

Acceleration of Growth by Radium.—Falta and Schwarz write briefly on the effects of emanations on plants, which they find to be intense. For instance, 96 oats were sowed on a narrow space and treated for 9 days with a definite number of emanations. Control cases showd that under radium the growth had been much greater. Other experiences lead to a general conclusion as to the uniform character of the results. So far as known, similar experiments have never been made save in the case of bacteria, in which case the results were contradictory.

Relationship between Kidneys, Adrenals, and High Blood-Pressure.—Frank discusses what he terms the hypertonic diathesis and nephrogenic hypertonia. The former is related to functional insufficiency of the kidneys, the efferent and interlobular vessels being primarily affected. The author thinks it is going too far to claim that the advance of this condition can lead to disappearance of the renal epithelia, which gives rise to hypertonia and primary contracted kidney. Nephrogenous hypertonia is a condition which pertains to kidney disease of several kinds and is so commonly accompanied by cardiac hypertrophy, and with this we are naturally familiar. The hypertonic diathesis, on the contrary, may involve other organs than the kidneys and heart, and depends more especially on the adrenals. That a given product of the latter, adrenalin, is responsible for a vascular syndrome is seductive, but only a hypothesis. The consideration of the hypertonic diathesis appears to show that arteriosclerosis as a whole is of two types. The true senile and presenile type has little to do with the diathesis. But it is otherwise with gout, chronic alcoholism, lead poisoning, etc., which probably occur in people with the diathesis.

Scapular Crepitus.—Habermann writes extensively on the causes and nature of that extrathoracic crackling heard in auscultation which so often leads to suspicion or diagnosis of apical tuberculosis. The literature of the subject is very large, and the cause is by no means always a single simple condition. It has been found to be a cartilaginous exostosis of the scapula, hygromata in various localities, etc. Terrillon once analyzed the types and localities of sounds heard, while others have adduced much testimony to show the condition may often be associated with certain occupations. Serratus paralysis has often been found in association with it. Röntgen rays have never been able to throw any light on any phase or form of this condition, although exostoses and fracture calluses have been known to determine the sounds. The present author places on record several cases in which cartilaginous scapular exostoses were extirpated. The crepitus had been present, but this type of cause is not likely very common.

Deutsche medizinische Wochenschrift.

April 6, 1911.

Phlegmon of the Gastric Wall Cured by Resection.—Koenig describes a subacute phlegmon which recovered under resection of the gastric wall. Such a result is a direct result of the progress in freeing the stomach from its surrounding tissues. Naturally such an operation is indicated only when an acute case has become chronic. A stomach abscess naturally differs from a diffuse phlegmon (which often produces death in a few hours); yet there is no fundamental distinction between the two. Koenig believes that a circumscribed lesion of the gastric wall may sometimes end in spontaneous cure. The pus may penetrate through the mucosa. The author cites as a form of case in which resection of the gastric wall can cure the patient the following: An acute phlegmon has become chronic before the case has taken a lethal course. Despite discharge of the pus into the stomach the patient may not recover, but remain an invalid. The phlegmon may be replaced, however, Koenig says, by a white tumor-like mass and then this mass may be successfully cut out.

Syndrome Comprising Subacute, Disseminated Myelitis and Recurring Endocarditis.—H. and F. H. Lewy sum up a case as follows: Patient first had the endocarditis, which lasted over 1¼ years, there having been three relapses with intervals of perfect health; then there developed similar relapses of myelitis and its membranes, the spinal affection being progressive. There were separate foci up and down the cord, and eventually the picture became one of acute, disseminate encephalomeningomyelitis. The spine must have suffered as a result of the endocarditis, but the authors admit their ignorance as to what extent infectious emboli and to what toxins were responsible.

Herpes Zoster and Renal Colic.—Kanera refers to an article on this subject by Bittorf, recently published in this journal. Despite the great rarity of this association, the author has just seen one like it. The coincidences indicate that similar cases are overlooked. Bittorf's patient had floating kidney and hydronephrosis. The author's patient, an elderly woman, consulted him for pain in the right hypochondrium. There was here also evident a floating kidney. A few days later the zoster broke out. The zoster in each case corresponded to the proper Head zone.

Kala-Azar in Greece.—As far back as 1842, according to Christomanos, a certain peculiar cachectic state has been known to exist, and has been known from time to time as cachectic anemia, pseudoleukemia, etc. Banti's disease or splenic anemia has doubtless been confounded with this syndrome, also chronic recurrent fever and syphilis. Several popular terms have also been applied to some of these conditions regarded as one. The disease alternately identified as kala-azar was a form of pseudoleukemia, apparently identical with or closely resembling Banti's disease in its clinical picture, but characterized by the parasites found in the liver and spleen originally described as occurring in kala-azar. The parasites were obtained during life from the pseudo-Banti disease by puncture of the spleen. That kala-azar has heretofore escaped recognition in Greece, etc., because of the great number and frequency of diseases with greatly enlarged spleen is more than probable. Besides ordinary malaria, syphilis, Banti's disease, and unknown forms of tropical splenomegaly, several severe types of fever are attended with the latter condition; such are typhoid fever, chronic recurrent fever, and several other infectious conditions, while pseudoleukemia of the commoner form should also be included.

Book Reviews.

Radium: Its Physics and Therapeutics. By Dawson Turner, B.A., M.D., F.R.C.P., Edin.; M.R.C.P., Lond.; F.R.S., Edin.; Lecturer on Medical Physics, Surgeons' Hall, Edinburgh; Additional Examiner in Medical Physics to the Edinburgh University, and to the Royal Colleges of Edinburgh and London; medical officer in charge of the electrical department of the Royal Infirmary, Edinburgh. Price $1.75. New York: William Wood & Company, 1911.

Dr. Turner has produced a very useful handy manual dealing with the physical phenomena of radioactivity and with the therapeutic uses of radium. The book contains in a condensed form the greater part of what has been investigated and written upon by authorities on these subjects, as well as the observations of the author. The manual will be found most interesting and instructive to those who desire a non-technical knowledge of the subject of radioactivity and it also will prove a valuable textbook for students

Education in Sexual Physiology and Hygiene. A Physician's Message. By Philip Zenner, Professor of Neurology in the medical department of the University of Cincinnati. Price $1.00. Cincinnati: The Robert Clarke Company, 1910.

In recent years, and especially during the last year or so, the social evil or evils have been widely discussed by physicians and laymen. It is recognized that if the matter is to be grappled with successfully the public must comprehend the main points of the question. The book under notice was written with the object in view of educating the youth of the country and the community at large with regard to the dangers of venereal disease. In Europe, or, at any rate, in parts of Europe, boys and girls in schools are given some instruction concerning sexual physiology and hygiene and Dr. Zenner's book shows how, in his opinion, this is best carried out. The work is clearly written and will be found a useful guide to parents and others who have the care of children and are responsible for their moral upbringing.

A Manual of Hygiene and Sanitation. By Seneca Egbert, A.M., M.D., Professor of Hygiene and Dean of the Medico-Chirurgical College of Philadelphia; Member of the Academy of Natural Sciences of Philadelphia; Member of the American Medical Association, etc. Fifth Edition, enlarged and thoroughly revised. Illustrated with 97 engravings. Philadelphia and New York: Lea & Febiger, 1910.

At a time when the importance of public health and sanitation is awakening the attention of lay writers and legislators, it is desirable that books on this subject should bear the authoritative stamp of medical men. The present volume, representing the fifth edition of this well-known work, apparently fulfills this requirement to the extent afforded within the limits of a small manual. The essentials of the subject are admirably presented, although one notes the absence of such important topics as bacillus carriers, the preventive inoculation of typhoid, and sexual hygiene, all of which ought to be included in an up-to-date manual of hygiene.

Primitive Psycho-Therapy and Quackery. By Robert Means Lawrence, M.D., Author of "The Magic of the Horse-Shoe," etc. Boston and New York: Houghton Mifflin Company, The Riverside Press, Cambridge, 1910. Price, $2.00.

The titles alone of the chapters of Dr. Lawrence's book are of a nature well calculated to stir the interest of any reader, for there is enough of superstition of one form or another still left subconsciously in nearly every one to lend a fascination to the records of beliefs that once were potent over whole races and nationalities. Medical amulets, talismans, the royal touch, the blue glass mania, styptic charms, metallotherapy, animal magnetism, healing spells, runic inscriptions—these are some of the topics which he discusses in a most pleasing literary vein. Physicians, especially, who so constantly witness the effects of imagination in influencing states of the body, should find pleasure and profit in reading of the spells and incantations, the laying on of hands, the cult of relics, and the countless other forms of treatment by suggestion that were the prototypes of various legitimate and illegitimate methods of appeal to the same agency that are current to-day. The latter part of the book is devoted to the subject of quacks and charlatanry, sores that have been always present on the body medical, but whose modern protagonists seldom reach the heights of reputation attained by Paracelsus or Cagliostro. To number Cardan and van Helmont among the "irregular practitioners" seems barely just, however, for eccentric as they may have been in some of their views, both made important contributions to science and occupied university chairs of prominence. Altogether, the book is a very worthy addition to the still far too scanty literature of the medical borderlands.

Sammlung klinische Abhandlungen über Pathologie und Therapie der Stoffwechsel und Ernährungsstörungen. Herausgegeben von Prof. Carl von Noorden. Neunte und zehnte Heft. Die Vagotonie. Eine klinische Studie von Dr. Hans Eppinger und Dr. Leo Hess (Wein). 2 M. 80. Berlin: August Hirschwald, 1910.

The authors of the present pamphlet, of ninety-nine pages, endeavor in their contribution to this well-known series of monographs to furnish a starting point for a future neurology of the internal viscera. While the pathology of the peripheral nervous system is fairly well understood, comparatively little is as yet known of the underlying factors in disturbances of visceral function, largely, of course, owing to the lack of precise information concerning the physiology of the so-called vegetative nervous system. Under the term "Vagotonie" the authors comprehend a state of hypersusceptibility of the autonomous sympathetic system, and make this responsible for the multitude of functional disorders associated with hysteria, neurasthenia, and nervousness. The essay is of much interest, particularly in regard to what is said concerning such conditions as the cardiac neuroses, asthma, anaphylaxis, gastric neurasthenia, etc., and the effects of atropine and adrenalin. It is most suggestive and very well worth reading.

Fractures and Separated Epiphyses. By Albert J. Walton, F.R.C.S. (Eng.), M.S. (Lond.), L.R.C.P., M.B., B.Sc. (Lond.), Surgical Registrar, London Hospital. New York: Longmans, Green & Co.; London: Edward Arnold, 1910.

The purpose of this book is to deal with the more practical aspect of fractures, and the author has aimed throughout at giving special attention to the smaller details of treatment, such as the application of splints, so that anyone having no special previous knowledge of this branch of surgery might find this book an aid to him in the practical treatment of any fracture. In these aims the author has succeeded in presenting an admirable handbook, valuable particularly because it is not overelaborate, omitting the rarer forms of fracture and the uncommon forms of treatment. The newer methods of treatment, such as the open method, and the subject of massage as advocated by the French school are fully presented. There are a large number of illustrations, including many *x*-ray pictures, all of which form an excellent feature of the book.

Practical Physiological Chemistry. By R. H. Aders Plimmer, D.Sc., Assistant Professor of Physiological chemistry University College, London. With colored plate and other illustrations in the text. London, New York, Bombay, and Calcutta: Longmans, Green & Co., 1910.

While numerous other books having just about the scope of this one have appeared during the last few years, careful examination of the present volume justifies the conclusion that it will find many users. This was to be expected of a work produced by so widely known an authority as Professor Plimmer, and this review of the essentials of physiological chemistry can only enhance his reputation. Although intended primarily for classroom use, the wide range of topics discussed and the clearness of presentation, together with the excellent arrangement adopted, make the book well adapted for purposes of reference as well as for the use of readers desirous of familiarizing themselves with the present status of the subject. Particular pains have been taken to keep before the student the relationship of physiological chemistry to organic chemistry as a whole, and though the subject-matter is divided into distinct sections these have been so grouped as to make a continuous and well knit presentation of the entire field. The only criticism that suggests itself is in relation to the chapter on metabolism and the quantitative determination of the various urinary constituents. This could with advantage have been made more ample, and the directions for the analysis are quite too concise to serve as satisfactory working guides. Some of the methods recommended also are unsuited for work pretending to the desirable degree of accuracy.

Puerperal Infection. By Arnold W. W. Lea, M.D., B.S. (Lond.), B. Sc. (Manch.), F.R.C.S (Eng.). Lecturer in Obstetrics and Gynecology, The University, Manchester; Surgeon, Northern Hospital for Women; Assistant Surgeon, St. Mary's Hospital; Manchester University Scholar and Gold Medallist in Obstetric Medicine. Price, $9.00. London: Henry Frowde, Oxford University Press, 1910.

Notwithstanding its great practical importance, nothing in the nature of a monograph on this subject has appeared in the English language and most of our textbooks have not given the matter the attention which it deserves. In the interesting historical review which serves as an introduction to this book, attention is attracted by the comparatively recent date from which our present day knowledge of the bacteriology of puerperal fever may be counted. For although the publication of the observations of Holmes and Semmelweiss on the contagiousness of puerperal fever marked an epoch in modern medicine, it was Pasteur who, in 1879, completely established the relation of bacterial organisms to puerperal infection. Notwithstanding the great advances which have been made in our knowledge of the prevention of septic infection and the consequent reduction of sepsis in general surgical practice, this cannot unfortunately be said of obstetrics, a branch of medicine in which the death rate from puerperal infection alone is unreasonably high. According to the statistics presented by the author it appears that the accidents of child-birth in England are responsible for an average of 2.5 deaths per 1,000, while the mortality from puerperal infection alone is only slightly less. This seems to be true in general practice outside of the hospitals everywhere and among women in whom operative interference has been undertaken the number of cases is especially large.

The book is divided into sixteen chapters and aims to present the complex manifestations of puerperal infection with scientific precision so far as this is obtainable. A great deal is now known regarding the essential nature of this affection and although much remains unsolved, we should be under obligations to the author for having presented to us a sufficiently extended source of information in this book.

Dr. Lea believes that we should modify our conception of puerperal infection as regards the nomenclature and be therefore classifies the disease according to the anatomical distribution of the various lesions. The important chapters on the bacteriology and etiology are very complete and extensive. The symptomatology of puerperal infection is very carefully described and extended attention is accorded to the subject of treatment. As a prophylactic measure in hospitals, the writer favors the isolation of patients in whom puerperal infection has developed, a procedure which in most institutions in this country at least, has not been generally adopted or else has been abandoned. In discussing the treatment of puerperal sepsis considerable space is devoted to the presentation of arguments for and against currettage. This operation the author seems to favor only in those cases where retained products cannot be removed by the finger. He believes that the character of the lochial discharge is important in deciding the method of procedure; if profuse and foul after uterine irrigation, the operation of curettage is a reasonable procedure, but if scanty or purulent it is contraindicated. This corresponds with the views generally accepted. The newer methods of treatment including the use of sera, vaccines, etc., are all considered and Dr. Lea concludes that at the present time the value of the antistreptococcus serum is questionable, as too much uncertainty attaches to the methods of preparation. He is inclined to accord greater value and importance to the opsonic treatment. The operative treatment of puerperal infection is very satisfactorily presented but summarized with the other methods, one is inclined to feel that much remains to be done before a successful solution of the problem is attained.

Dr. Lea's book fills a long felt want in presenting to the English reading public a complete and well arranged presentation of this important subject and constitutes a most valuable and much needed reference manual. Every branch of the subject is fully discussed and in the pathological features of this disease alone a great deal of material is presented which is usually foreign to the contents of English textbooks. Aside from what is contained in the obstetrical manuals of Williams and Hirst, an insufficient amount of attention has been accorded to the pathology of puerperal infection in American and English textbooks and the presentation of the subject as here given is a most welcome addition to the literature. The book is well printed and sufficiently illustrated and at the end of each chapter is a list of the more important bibliographical references.

Movable Kidney. Its Etiology, Pathology, Diagnosis, Symptoms, and Treatment. By William Billington, M.S. (Lond.), F.R.C.S.; Senior Surgeon to Out-Patients, Queen's Hospital, Birmingham. With 12 full-page plates and illustrations in the text. London, New York, Toronto, and Melbourne: Cassell & Company, Ltd., 1910.

This book is based on extensive clinical experience and goes a great way toward clearing up the controversy that has existed as to the importance of movable kidney in the causation of ill-health. This controversy chiefly centers about the frequency with which movable kidney causes serious symptoms, and about the possibility of its causing functional nervous and mental derangements. The author discusses the position, relations, and supports of the normal kidney; the frequency and etiology of movable kidney, the pathological changes in the kidney and in surrounding structures, the general pathology of movable kidney, the diagnosis of this condition, and in separate chapters are discussed the symptoms, pain, disorders of the sexual organs, disorders of digestion, disorders of the nervous system, and disorders of the mind. The treatment of movable kidney, the operation of nephropexy, and the author's technique are each described in separate chapters. In the etiology of this condition the following factors are detailed: Heredity, trauma, errors of dress, pregnancy and the puerperium, constipation, and pathological changes in or near the kidneys. It is noted that the urine in all the acute accidents of movable kidney gives unmistakable evidence of great interference with the functions of the kidney, and of severe injury to its secreting structures. On this and other evidence, taken in conjunction with the clinical manifestations of movable kidney, the author holds that it is difficult to arrive at any other verdict than that kidneys which are movable are frequently unable freely to eliminate the body's waste products, and that these accumulate and cause a general toxemia. The frequency with which movable kidney occurs, and the large number of symptoms that are attributable to this disorder, render this subject one about which the general practitioner should acquire definite knowledge. This may be amply supplied by a careful reading o fthe present volume. It deserves wide circulation.

The Prevention of Sexual Diseases. By Victor G. Vecki, M.D., Ex-President San Francisco German Medical Society. Member American Urological Association, American Medical Association, California State Medical Society. With Introduction by William J. Robinson, M.D. $1.50. New York: The Critic and Guide Company, 1910.

In this little volume the author discusses the reality of the venereal peril, the sexual diseases, the question of ignorance versus knowledge, prostitution, supervision versus the open door, the government's duty toward prevention of venereal diseases, the physician's duty toward prevention of sexual diseases, individual prophylaxis, and the physician's personal prophylaxis. The book is a plain-spoken sermon on an important subject and deserves wide reading.

Refraction and Motility of the Eye. With Chapters on Color Blindness and the Fields of Vision; Designed for Students and Practitioners. By Ellice M. Alger, M.D., New York. Adjunct Professor of Ophthalmology at the New York Post-Graduate Medical School, Ophthalmologist to the New York Dispensary, etc. With 122 illustrations. Philadelphia: F. A. Davis Company, 1910.

The student of refraction who acquires Dr. Alger's work should first read the introduction, as it gives excellent hints regarding what the student should seek to know, also in regard to the limitations of the subject. The book is one of 380 pages, well printed, and sufficiently well illustrated. The first chapter is devoted to optics, then follows a chapter on anatomy and physiologic optics, both being treated in an elementary way. The various errors of refraction, the motility of the eye and its anomalies, and the color sense are considered in separate chapters. The work is intended to supply the needs of "the general practitioner and of the embryo ophthalmologist in this part of ophthalmology." It is quite well written to fulfill its purpose, and its teachings may be safely followed. There is a suggestion of vagueness throughout the text, which we wish did not exist.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

238th Regular Meeting, Held March 3, 1911.

The President, Dr. H. M. Biggs, in the Chair.

Psychasthenia Treated by Hypnosis and Freud's Method.—Dr. C. L. Dana presented a patient suffering from psychasthenia, with symptoms of depression, morbid fears, doubts, dreamy states, and a sense of unreality. The patient had been under the care of Dr. W. H. Frinck, at the Cornell Clinic, who had treated her first by suggestion, and later by the psychoanalytical and cathartic method of Freud. The patient illustrated in a rather typical way the technique of this new method. In introducing the case Dr. Dana spoke of the general principles underlying the method, which had been mainly worked out by Freud. There existed in the subconscious mind of certain people emotional states, produced often by shock or trauma in early life. The ideas and feelings connected with these early shocks had disappeared from conscious memory and were no longer part of the patient's life, so far as he or she was aware. The presence of these nuclei of irritation in the subconsciousness acted in an injurious manner upon the general mental condition of the patient, producing irritation, nervousness, depression, obsessions, and similar phenomena which were observed in psychasthenia. The object of the Freud method was to bring into the memory of the patient the facts regarding this early emotional trauma, and to reawaken the latent associations and explain the situation to the patient. In this way the subconscious irritation was brought into consciousness and explained away; new and normal associations were formed and the patient got well. The methods employed in finding this subconscious nidus were: (1) That of ordinary interrogation; (2) that of psychoanalysis, by means of association tests; (3) the use of word associations; (4) the study of dream states. These methods were all employed by Dr. Frinck in the treatment of the patient under consideration. The following was the history as first obtained: Mrs. V., aged 23; two children, family history negative. The early history of the patient, as first given, was negative, that is to say, she said that she was well as a child and had been subjected to no shocks or emotional disturbances, though she admitted having had an unimportant love affair. She had been married for three years, had one child, now a year old, and had a miscarriage seven months ago. Her habits were good: menstruation was normal. She stated that three weeks after her child was born, she had "nervous chills" and then began to have very distressing dreamlike states in which things seemed strange and unreal to her. She became extremely depressed and had a constant feeling of going insane, was afraid of being alone, afraid of having consumption, had morbid doubts, and could not make up her mind about even trivial things. There were no severe pains; no special digestive disturbances. She stated that her married life was normal and happy. Physical examination was practically negative. She was well nourished and not anemic. There was a slight tremor of the hands. The cranial nerves were normal. Reflexes were normal, and there were no evidences of organic disease, no stigmata of hysteria, though the conjunctival reflexes were absent. Dr. Frinck at first had treated her by suggestion for some time but without any results. This treatment lasted at intervals from April to October, 1910. He then began to treat her by the method of psychoanalysis and mental catharsis, using the association test of seventy-five words. He found on studying the delayed reactions, an erotic complex twenty times, the average delay being four seconds. He found a minor complex, associated with home, nine times, with the average delay of 2.7 seconds. Following up the lead obtained by the delayed association in the erotic complex, he brought out a very different kind of history, which was as follows: The story of the patient as worked out by the association test, in hypnosis, and a little from her dreams, was that when she was six years old another girl aroused her interest in sexual matters and taught her to masturbate. Masturbation continued until the patient was about fourteen years old; then, through the confessional, she learned to look upon the habit as sinful and disgusting, and she was able to stop it. From that time she felt a disgust for frankly sexual matters, and her life was all it should be until she was married. She claimed that she never again experienced erotic feelings until after her marriage. When she was fourteen years old she went to work in a factory. The superintendent, who was a very handsome young man, immediately attracted her attention and almost from the first she found herself indulging in romantic dreams concerning him. He was far above her socially, but this did not prevent her from thinking about him. He made many advances toward her, but, though this was just what she wanted, she was always overcome by a feeling of shyness on such occasions, and was never able to meet him half way. As a matter of fact she spoke to him but four or five times, though she saw him continually, as she worked in the factory until she was married. She related many little episodes in which she found him watching her, where she heard him saying nice things about her, etc.; and all these matters, though trivial in themselves, served to keep up her romantic affection for him. When she was about nineteen, the brother of this man, who worked in the same factory, began to pay her attentions and finally asked her to marry him. This brother had a very inferior position and was in no way equal to the superintendent, but, as she was very tired of working, and the superintendent seemed out of her reach, she finally persuaded herself that she cared for him and shortly after this they were married. When the man, who is now her husband, told his brother of the engagement, he said very nice things about her, and these remarks and some other gossip that was repeated to her gave her the impression that the superintendent was by no means indifferent to her, and this impression was strengthened by the fact that he very suddenly married a week before she did. Since her marriage she had heard from various sources that this man claimed to be in love with her, that he was unhappy with his wife, etc. He was well off and had very little to do with her husband, so that she had only seen him once since her marriage. That was at the funeral of her aunt. Her husband was very good to her and she realized that she ought to forget about the other man, and after a time managed to repress her thoughts of him until she thought she had succeeded. Her task was made difficult by the fact that she heard a good deal of gossip that led her to believe that the man she admired was still in love with her. When the patient first came to the clinic she was treated by hypnotic suggestion without any more attempt at an analysis than was given on the history blank. She was a pretty good hypnotic subject and the treatments given twice a week would make her feel perfectly well for about twenty-four hours, but then all her symptoms would come back and she would feel as badly as ever, and at the end of a month of this her condition was really not improved at all. Then an analysis was undertaken which revealed the infantile traumata, and she improved immediately and was practically well for a month. Then she visited a sick relative in the hospital and her fear of insanity returned. She was treated by suggestion a few times and she felt pretty well again. She did not visit the clinic again during the summer, but came back in October saying that in the summer her fear of insanity had returned again. Her depression had disappeared apparently. She had visited

the clinic a few times since then, but as she had moved to Brooklyn she could not come often. She still had some dislike of being alone and the feeling of unreality occasionally, but this did not last long, and on the whole she had improved a good deal. The explanation to the patient was about as follows: When she had stopped the habit of masturbation and had learned to look upon such things as worthy of reproach she had endeavored to forget these unpleasant facts about herself and was finally successful. She then went to the other extreme as a compensation and was inclined to be shy and prudish, as manifested in her attitude toward the superintendent. Her sexual instinct, which was over-developed presumably by her early sexual activity, manifested itself in romantic day dreams only, as to this form of gratification no reproach could be attached. When she married she was prevented from adjusting herself to her husband by the memory of his brother, and their sexual life, though satisfactory in a physical way, was not so psychically and a certain amount of sexual excitement was prevented from escaping in the normal way. This excitement, which was dammed up, so to speak, then sought to escape by the infantile route, and this brought about a failure of repression. That is, it gave rise unconsciously to a desire for the same form of gratification which had satisfied her in early childhood. This of course tended to bring to consciousness the forgotten reproaches that had been attached to the thought of masturbation, but the unpleasant emotion was detached from the idea to which it really belonged and reattached to an associated but less significant idea. The fears, etc., were further determined by certain adult experiences which tended to produce the same emotion and which she wished to forget. Thus her depression was self-reproach for masturbation, further determined by reproach for ideas of infidelity, etc. Her fear of insanity and of tuberculosis was really a fear of masturbation, which she had been told caused insanity and tuberculosis. Her fear of being alone was a fear of masturbation and of later erotic thoughts in which she indulged while alone. The feeling of unreality originated from the fact that while one part of her personality lived with her husband and baby, another and unconscious part lived in the past with her lover. The globus might be connected with the thing she refused to tell. Her doubts, etc., originated from doubts as to her morality, her fidelity, and from attempts to reason away all these feelings of remorse, etc., that seemed peculiar to her. Dr. Frinck later made a study of her dreams which showed also an erotic complex, and explanations of these helped her still further. The speaker thought that the case and its method of treatment were well worth bringing to the attention of the Practitioners' Society because the method in some form had come to stay, and in some modified form it would become a part of modern therapeutics.

Dr. L. A. Conner asked how this association word test was carried out.

Dr. Frinck said that the words were read off one at a time and that the patient was instructed to reply with the first word thought of, and that the time of reply was taken with a stop watch. The first word that was given to the patient was house and that she replied with the word building in two seconds. To the word secret she did not reply at all, saying that she could not think of anything. To the word hotel in ten seconds she replied with the word street. The list was gone over a second time to learn if she remembered what she had answered. The speaker asked her about the word secret, taking up some memory, and he learned that it referred to some erotic feeling. It was put down together with the others and figured out to be an erotic complex.

Dr. R. Abbe asked if they could differentiate a weak mind from an insane one. He said that people of this type of mind drifted into insanity, and he inquired if they were put with persons who had become insane, could they restore them.

Dr. Dana replied that if they were psychasthenics they would drift into dementia præcox.

Dr. Abbe inquired if it were not the conditions under which the patient lived that kept her in that state, and if under more favorable circumstances she would get well.

Dr. Dana said the patient lived alone a great deal of the time, as the husband's work was hard and kept him away at times at night, and if she could be placed in different surroundings it would be better for her. The whole trouble was one of environment, which in her case was very poor.

Pulmonary Symptoms as Premonitory Signs of Venous Thrombosis.—By Dr. Lewis A. Conner. (See page 753.)

Dr. James stated that he thought it a very interesting hypothesis that many of the minor complications in these diseases were due to small pulmonary emboli. At any rate it was evident that pulmonary infarct was a much more common occurrence than was usually supposed and unfortunately was not expected and looked for enough by physicians.

Dr. L. A. Conner said that he had worded his description so in order to save details, and that what he meant to indicate was that there were signs of consolidation in a small area.

Dr. Abbe was inclined to the belief that these coincident attacks of pulmonary phlebitis were associated with a phlebitis in other parts of the body, and that the onset of the phlebitis was in the lower extremity, due to some irritating force setting up the phlebitis rather than an infarct. He had a case last year where the pulmonary symptoms were preceded by a weak phlebitis of the leg which showed that the trouble was in the venous system, which was followed later by a thrombosis of the leg. He said that multiple phlebitis was due to an arterial infection. The attacks of phlebitis with secondary pulmonary trouble that were seen in surgical cases had always been very grave and fatal. Minor attacks were due to a chemical process in the blood which set up conditions of multiple phlebitis.

Dr. A. A. Smith was interested in the conclusion or rather the suggestion of Dr. Conner, if it was a fact that we were going to be able to anticipate probable phlebitis with thrombosis with pulmonary symptoms, and he said that it behooved all observers to be on the lookout for phlebitis to see if these suggestions could be confirmed.

Dr. S. W. Lambert said that he had seen one of the cases reported by Dr. Conner, and that quite recently he had seen the direct counterpart of that case in a patient with an attack of grippe. This patient had started with an ordinary grippe and bronchopneumonia, and was apparently getting well when he was suddenly taken ill with pulmonary symptoms and signs of consolidation in the lung opposite to that in which he had the bronchopneumonia. On the fourth day thereafter he had developed a venous thrombosis in the calf of the leg. It was the exact clinical picture of the typhoid case he had seen last summer with Dr. Conner. The point made in regard to surgery, the speaker said, could be applied to obstetrical cases where the labor was severe and rapid. Dilatation and damage of the soft parts in forced deliveries was not infrequently followed by emboli from the veins of the pelvis though not necessarily accompanied by a thrombosis in the veins of the leg.

Dr. J. A. Blake said that he differed from Dr. Conner on the point that the serious and fatal cases of pulmonary embolism always occurred late in the course of a thrombophlebitis. In the cases of pulmonary embolism occurring after operations for appendicitis, the patients were usually apparently well and normal and the fatal embolism took place early, between the fifth and twelfth day after opera-

tion, without preliminary signs of phlebitis. The question of thrombophlebitis after appendicitis, the speaker said, was a very important and serious one. According to statistics, it occurred in from eight to ten per cent. of operations for appendicitis. He himself thought that this statement of the percentage was rather high, but nevertheless it was a very common complication; in fact, it was the chief cause of death after operations for appendicitis in the interval. He knew of one surgeon who in a single summer had had three deaths from this cause after appendicitis done in the interval. In some of these cases the thrombosis increased in size in the pulmonary artery after its lodgment there. An example of this occurred in a case of his that had had an exploratory operation for cancer of the rectum in which the growth had been thought to be inoperable and the abdomen was immediately closed. This patient developed thrombosis of the pulmonary artery on the fifth day, and at autopsy it was found to be a very large thrombus filling the bifurcation of the pulmonary artery saddle-wise, so large that it could not possibly have passed through the heart. It was difficult to say in such a case whether the thrombosis occurred *de novo* in the pulmonary artery, or had been transferred from elsewhere. The patient lived about two hours after the onset of the symptoms.

Dr. C. L. Gibson stated that surgical thrombosis following operation was a different matter from that in Dr. Conner's paper, because here we had a very obvious lesion. The autopsy on cases following an interval operation for appendicitis showed a clean wound and a normal blocking of the vessels that had been tied and nothing between the site of the thrombosis and the lesion. There was no explanation that could be offered, although he thought it was possible that our modern methods of making small incisions might have something to do with it, for in order to get at the appendix the gut was pulled up through small incisions, but our German friends, who made large incisions, seemed also to have their share of postoperative emboli. Statistics show that a large proportion of these thromboses occurred within 48 hours after operation. He was unable to explain why we had these thromboses after abdominal operations and not after operations on the upper part of the body. The speaker also noted the fact that phlebitis never occurred on the right but always on the left side, and that it was far from clear in his mind why this was so. The blame for these conditions had been attributed by some to milk diet.

Dr. Blake said that some surgeons claimed that getting their patients up early prevented thrombosis. This he felt was a dangerous thing to do.

Dr. Gibson did not think that getting the patients up early applied at all.

Dr. Abbe recalled that Dr. Richardson looked up this same point and wrote that the more patients were permitted to thrash about in bed the better it prevented thrombosis, and that Dr. Keen said that there was an anatomical reason why thrombosis was on the left rather than on the right side, and that he too stated that the patients should be permitted to thrash around in bed and that they should be gotten up on the fifth day.

Dr. James stated that of late years he had a growing conviction that it was not always a good plan to keep a patient quiet and flat in bed for a long time in acute disease; and that perhaps some tendency to complications would be avoided if patients would be allowed to sit up earlier. It was traditional among nurses and most physicians to keep typhoid fever and pneumonia patients quiet and flat until they were almost well and pillows were allowed them grudgingly. It was thought that the time would come when a less rigid line of demarkation would be drawn between sick and well and when patients with acute disease would be allowed more solid food and would be allowed to shift more in bed, unless there were some contraindications. There was much less danger connected with having a case of pneumonia sit up for examination than was commonly supposed, and the rare cases of sudden death in pneumonia did not seem to follow such exertion. Occasionally one had met with pneumonia in a very obstinate case, the patient insisting upon sitting on a commode each day throughout the illness, and it seemed to make no difference in the recovery.

Dr. Francis Kinnicutt said that not only had Virchow long ago pointed out that the anatomical relations of the right common iliac artery and the left common iliac vein might well contribute to the much more frequent occurrence of thrombosis on the left side of the artery as it crosses the vein exerting a certain amount of pressure upon it, but recent demonstrations by McMurrich of Toronto had suggested a further explanation of this phenemonon. McMurrich had examined the iliac veins in 107 individuals and had found congenital adhesions in 32.7 per cent. The adhesions presented several types, the two principal types being respectively (first) a fusion of the anterior and posterior walls of the veins, a diminution or division of the lumen being thereby produced; (second) an adhesion marginal in position, occurring at the lateral borders of the vein, so that the lumen was merely diminished but not divided. A most striking peculiarity in the distribution of the adhesions was their preponderance in the left vein; the adhesions in the left vein formed 91.4 per cent. of the total number of veins examined. The significance of these data in connection with the occurrence of iliac and femoral thrombosis seemed very striking. Dr. Kinnicutt believed that the primary cause of phlebitis with thrombosis was almost always of an infectious nature.

Dr. L. A. Conner said that he was not certain from Dr. Abbe's remarks whether he had in mind thrombosis of the pulmonary artery or of the vein. Thrombosis of the latter was very rare: it did not lead to pulmonary infarction, and its symptoms were unrecognizable. Thrombosis of the pulmonary artery would give symptoms indistinguishable from those of embolism, but there was much evidence to support the view that in the type of case under consideration the pulmonary symptoms were due to lodgement of an embolus and not to the formation of a thrombus in the artery. These symptoms he thought were often quite characteristic, especially in their suddenness of onset and their short and mild course, and one could often be fairly sure of their embolic nature even before there were any signs of venous thrombosis. Our ideas, too, of venous thrombosis and phlebitis would, he thought, have to change radically and we would have to recognize the fact that these occurred much more frequently than was commonly supposed, and that the classical symptoms of involvement of the large veins were frequently lacking. Chiari, in his recent Harvey lecture, had referred to the fact that in his autopsies he had frequently found thrombosis of the small veins of the leg when the larger veins, such as the femoral, were quite free from trouble. Referring to Dr. Blake's statement that fatal pulmonary embolism after operation often occurred within a very few days of the operation he explained that he had not meant to imply that such an embolism always occurred late in convalescence, but only that the large emboli, necessary to cause a plugging of the pulmonary artery, usually represented a later stage in the development of the venous thrombosis than did the small emboli, although the whole period of time covered might be very short.

Castration in the Treatment of Mammary Carcinoma.—F. Cahen reports the good palliative results of this method in three out of seven cases in which it was tried. The palliative effect was seen only in the case of young women.—*Deutsche Zeitschrift für Chirurgie.*

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, Held February 3, 1911.

DR. GEORGE WOOLSEY IN THE CHAIR.

Benign Intramedullary Tumor of the Femur with Spontaneous Fracture; Enucleation; Recovery.—Dr. DEWITT STETTEN presented a patient, 23 years old, who had suffered from a chronic apical tuberculosis for four or five years. There was no history of syphilis. For six months prior to the time he came under his observation he complained of pain in the left hip and he had a bad limp which began suddenly and gradually progressed. A tuberculous coxitis in the incipient stage was suspected. On June 28, 1910, while in the country, he had a fall and was unable to walk afterward. A diagnosis of fracture of the hip, possibly complicating a tuberculous focus, was made. A splint was applied and he returned to the city and was referred to Dr. Stetten. On admission to the hospital, July 5, 1910, the examination disclosed a somewhat undernourished young man, with slight signs of a bilateral apical tuberculosis. There was about 1.5 cm. shortening of the left leg. He was unable to move this extremity. There was no eversion or other deformity, except that the upper border of the great trochanter was a little above the Nélaton-Roser line and the base of Bryant's triangle was slightly shortened. The *x*-ray picture showed a rarification of the upper end of the femur, from the great trochanter to about 9 cm. below it and running toward the neck. There was a fissure in the neck of the bone at the upper pole of the rarified area and a traumatic coxa vera. There was no expansion of the cortex. A diagnosis of cyst of the femur with fracture of the neck was made and it was decided to treat the case conservatively for the time being. A plaster cast was applied for a week and then a Buck's extension apparatus; this was removed at the end of four weeks. A few days later while moving in bed the patient felt something give way and he complained of severe pain in the upper part of the thigh. The examination showed a marked bowing of the upper part of the femur, with over 10 cm. shortening. The radiograph showed a decided increase in the degree of rarification, still without expansion, and a transverse fracture of the shaft at the lower pole of the rarified area. The extension apparatus was at once reapplied and operation was decided upon for what was supposed to be merely a bone cyst. On August 25, 1910, a longitudinal incision was made on the outer side of the thigh, exposing the upper part of the shaft of the femur. The bone was entirely gone. He did not enter a cavity, as he expected to, but cut into a very hard, solid tumor. This was enucleated subperiosteally and without much difficulty. He then thoroughly curetted the cavity. The femur was eroded in its entire thickness and a defect of at least 10 cm. between the neck and the upper end of the shaft was left. A spur of bone with the lesser trochanter was still attached to the neck. The wound was packed with iodoform gauze and left wide open. The leg was put into an extension apparatus. He hoped that a subperiosteal bone formation would occur which would fill in the defect and unite the two fragments. He was not disappointed, as the radiographs and final clinical results showed. Within six weeks there was good union, the extension apparatus having been removed one month after the operation. The wound was kept tightly packed so that no sinuses would form and healing would take place from the bottom up. It took four months to close. About six weeks after the operation the patient was allowed to get up, but a Thomas' hip splint was worn for about two months to guard against refracture. Since the first of the year the splint and crutches had been discarded and the patient walked well with only a cane and at times even without this. Rapid improvement in his walk was taking place. The last *x*-ray picture, taken over three months ago, showed a very fair replacement of the defect and solid union. There was less than 0.75 cm. shortening. There was no coxa vara. There was no eversion and with the exception of a slight contracture of the adductors, the movements of the hip joint were freer than on the other side. The specimen presented was a hard, lobulated tumor with a definite fibrous capsule. The microscopical examination showed it to be a benign fibro-chondroma, with a tendency to ossification of the cartilaginous islands.

Resection of the Inferior Maxilla and Cheek for Carcinoma—Plastic Repair.—Dr. GEORGE H. SEMKEN presented a man, 55 years old. The family and personal histories were negative. Three years ago he had a necrosis of the right lower cheek; he consulted a dentist who removed a tooth, hoping to relieve the irritation. It did not relieve the irritation or stop the developing neoplasm. When Dr. Semken first saw him, the patient had a very extensive involvement of the right cheek which was shown on a diagram he presented. The question as to operation came up; because of clean tissues it was decided that operation would be successful. A plastic operation was done, which was followed by splendid results. The operation was described in detail, and the specimen removed shown. Artificial jaws which could be molded into form under hot water were shown.

Two Cases of Lung Abscess.—Dr. A. A. BERG presented these patients. CASE I. This patient had a cholecystitis. He had a number of chills for two days, two chills on the third day after his seizure, etc., with a corresponding rise and fall of temperature and perspiration. All evidences of cholecystitis were very marked. Operation was advised. The gallbladder was found to be very much distended, walls thin and containing necrotic material. The cause for the number of chills prior to the operation seemed to be some lesion of the vein. At operation the arteries bled freely. The cystic vein was patent. The patient was out of bed on the third day after operation. At the end of the third week he had an intense cough and gave the physicial signs of a pleurisy at the base of the right chest. One evening he had a chill and a rise of temperature to 102° F. The physical examination made out no evidence of any process at the base of the right lung. The temperature ranged from 100.5° to 102° F. The patient's physical condition remained excellent, and it was thought that he only had a basilar pleurisy. He was suddenly seized with another chill, dyspnea and expectoration, and the physical signs then revealed consolidation at the base of the right lung with compression signs. Several aspirations for fluid were made, but all proved negative. The cause of these compression signs at the base of the right lung and the foul expectoration interested Dr. Manges; he thought that there was in all probability an embolic pneumonia present which had resulted in the formation of an abscess. The patient's condition became desperate. He had a pulse of 130 to 140; he was very cyanotic and expectorated an abundance of fetid material. On Christmas morning he had another chill and an operation became imperative. The base of the right lung was exposed posteriorly. Under cocaine anesthesia aspirations were made in ten or fifteen directions, but no pus was found, and so further work was not done. The patient bore this operation well. One week later Dr. Berg again aspirated and through one of the holes made at the previous operation he found a few drops of pus. This pus was very fetid. The finding of pus through one of the openings made at the previous operation was very interesting.

CASE II. One year ago, during a holdup out west,

this patient was shot, the bullet passing through the thoracic cavity. He was taken to a hospital and a laparotomy performed with the idea that the bullet might have penetrated the peritoneal cavity and done damage. Pads were packed into the opening and the patient returned to bed. The bullet emerged spontaneously. His convalescence was very slow. Several weeks afterwards, because of signs at the base of the left chest, an incision was made through the thorax posteriorly. Several weeks later the patient came east with a profusely discharging fistula and with signs of consolidation over the entire lower lobe of the left lung. Aspiration through one of the intercostal spaces withdrew pus and thorocotomy was advised. The incision was made as shown and a pus cavity entered. To effect the obliteration of the pleural cavity the removal of several cartilages became necessary. The patient made an excellent recovery.

A Case of Liver Abscess Which Ruptured into the Lung.—Dr. A. A. Berg reported this case. The patient was 4 years old when admitted to the hospital and had been under observation for several weeks. The history obtained was that the child had had pain in the upper part of the right hypochondrium, the lower thorax, as well as pain in the right shoulder. The temperature was slightly elevated and there were some evening sweats. After a prolonged period of observation, during which they were unable to find pus, the patient was discharged. Several weeks after being discharged the child commenced to expectorate profusely a very fetid material. The child was again brought to the hospital Dr. Berg found signs of an enlarged liver and evidences of fluid in the right chest. The expectoration was very profuse, very fetid and brownish in color. At operation a large abscess of the liver was found. The child made a good convalescence.

Two Cases of Gastric Ulcer Due to Diseased Gallbladder and Appendix.—Dr. Aspinwall Judd presented these patients. Case I. Three years ago this woman suffered from the classical symptoms of gastric ulcer. At operation he found two ulcers, one the size of the finger nail, the other somewhat smaller. They were excised and a good recovery followed. Fifteen months later she suffered again with practically all the symptoms she had during her first attack, except that the homorrhages were not so profuse. She was turned over to the medical side, and in three weeks' time her symptoms had disappeared. Three months ago she returned again suffering from symptoms she previously had suffered from, and with the hemorrhages more profuse. She was anemic and much emaciated. He excised the old scar. He found perfect healing of the sites of the ulcers. He then looked for the appendix and found many omental adhesions. He found it necessary to do a posterior gastroenterostomy. An uneventful recovery followed this operation.

Case II. This patient was a woman with symptoms of marked anemia, nausea, vomiting, constipation, slight jaundice, and tenderness over the appendix. A small resisting mass could be felt. She suffered from considerable gastric hemorrhage the day of operation. The usual incision was made. She took the anesthetic badly, respirations falling to six and seven per minute. He found an enormously distended gallbladder which was bound down by adhesions to the duodenum, omentum and liver. Because of her bad condition he worked rapidly on the gallbladder, quickly turning out the bile. He found no gallstones and the gall ducts were patent. He then found an ulcer on the anterior wall of the stomach; this he excised and almost at once the respirations went up to the normal. The patient then made a good recovery.

A Case of Mesenteric Cyst.—Dr. George Franklin Shiels reported the case of a woman, 41 years old. She had periodical attacks of vomiting and Dr. Shiels was called in consultation. He found her after the strain of vomiting in a state of collapse and with signs of obstruction. He cut through the left rectus muscle and found nothing in the stomach. After going over the intestines very carefully he at last ran across a mesenteric cyst in the ascending meso-colon and this had caused intestinal obstruction. The case was reported because of its rarity. A sketch was shown which gave a splendid idea of the condition.

The Chemistry of Proteins and Proteolytic Ferments in Relation to Surgery.—Dr. William G. Lyle read the paper of the evening. He said that protein food, after reaching the stomach, was digested by pepsin acting in an acid medium. This process proceeded as far as albumoses and peptones only, and was in reality but a preparatory change of the insoluble colloidal protein to its more readily soluble form. Pepsin, unlike trypsin and erepsin, did not split the proteid molecule to its basic constituents, *i. e.*, amino acids or their combinations with one another known as peptides. This was important to remember, because the glycyl-tryptophan test for carcinoma of the stomach was based upon this fact. The simplest amino-acids, such as glycocol and alanin, belonged to the aliphatic series; they were formed from the lower fatty acids by the substitution of an H by an NH_2 group. Other amino acids, such as tyrosin and tryptophan, contained besides the amino group a phenol ring, and belonged to the aromatic series. The presence of this aromatic group was of importance because such substances as gelatine, which did not contain it, had less nutritive value. If amino acids were the final products of protein digestion, and as such passed through the intestinal wall, and were then resynthetized and could keep the body in nitrogenous equilibrum, a mixture of these substances would be of great practical value in rectal feeding after abdominal operations. Abderhalden had shown that by digesting fat-free meat with pepsin, trypsin, and erepsin for a long time a mixture of amino acids resulted. This had been called ereptin. In a preliminary investigation with this they had given 100 grams of ereptin with 100 grams of glucose dissolved in 1000 c.c., of water; 200 c.c. of this mixture were given at five different periods during the day. The solution was readily absorbed, and could be introduced by the Murphy drop method without discomfort. The ability of trypsin to liberate tyrosin from its combinations, and the facility with which this amino acid could be subsequently recognized by its crystalline form, were useful in the diagnosis of pancreatic diseases. This method was as follows: 22 c.c., of olive oil were given on an empty stomach followed by magnesia usta to neutralize the hydrochloric acid. The resulting regurgitated fluid, which, in the majority of cases, contained trypsin, was removed from the stomach, added to a 50 per cent. solution of Seiden peptone (Roche) which contained a high percentage of tyrosin. The mixture was covered with toluol, and after three or four days' incubation at 38° was examined microscopically for the presence of tyrosin crystals, the latter indicating tryptic digestion. Polypeptides might be classified as di-tri-tetra peptides, etc., depending on the number of molecules of amino acids present. He spoke of two dipeptides, *i.e.*, glycyl-glycin and glycyl-tryptophan. The glycyl-glycin was a combination of two molecules of glycocol and was useful for differentiating the ferment action of erepsin from that of trypsin. Fischer and Abderhalden had shown that although it was unattached by trypsin, erepsin was able to split it. Recent studies of the ferments had shown that erepsin was widely distributed; it was present in many organs and tissues, and was possibly the proteolytic ferment of both the leucocytes and of carcinoma. The other dipeptide was glycyl-tryptophan; this as is known had been used as a test

for carcinoma of the stomach. The technique of this procedure was described by Dr. Kober and the writer in the *New York Medical Journal*, June 4, 1910. They had examined, in all, 93 cases of suspected carcinoma of the stomach, 30 of which had been operated upon, one autopsy; 19 of these cases proved to be carcinoma; of these all gave a positive reaction, with the exception of one, in which the color developed in 48 hours instead of 24. Of the eleven negative cases, nine gave a negative result; one, a pancreatic cyst, gave a negative and a positive, and the other gave a positive result from a single examination; this one turned out to be an infected gallbladder with no free hydrochloric acid in the stomach. In drawing conclusions from the test, one must be sure that trypsin had not regurgitated. It was safer to discard all test meals with a greenish appearance, even though the tests for bile were negative. Not less than three, or better five tests, should be done on each case.

Pathological Society of Philadelphia.

At a joint meeting held with the New York Pathological Society on February 9, Dr. Howard T. Karsner demonstrated an "Cerebellar Abscess Containing the Micrococcus Cereus in Pure Culture." The specimen came from an elderly man who had had pneumonia a year previously, followed by abscess of the lung. After many months, symptoms of cerebellar abscess appeared, terminating fatally. The autopsy revealed a large abscess of the cerebellum, involving especially the middle lobe, but extending also to the lateral lobes. From the contained pus the micrococcus cereus was obtained in pure culture. The abscess in the lung had been contaminated by embalming fluid, and the pus from this source was not cultivated. The micrococcus failed to exhibit pathogenic activity in inoculation tests on lower animals. Dr. D. T. Pfeiffer demonstrated for Dr. A. O. J. Kelly a specimen of "Hydatidiform Mole." The formation was obtained from a woman presenting uterine hemorrhage following a period of menstrual suppression. The uterus was removed with its contents and these were found to have an extensive attachment to the endometrium. Dr. E. H. Goodman presented a communication entitled "Isolation of Copper from the Sweat and Urine of a Brass-Worker." The patient was an elderly man with symptoms of metallic intoxication, who had been a brassworker for forty-seven years. He stated that his undershirt became stained with green-colored sweat. Examination of a portion of such a shirt and also of the urine disclosed the presence of copper. Dr. Allen J. Smith demonstrated a specimen of *Schistosoma japonicum* and one of *Hæmatobium*. Dr. M. E. Pennington presented a communication entitled "A Scientific Study of the Deterioration of Poultry During Marketing." She showed by bacteriological and chemical tests that the flesh of poultry obtained in the far Northwest, there treated and stored and thence shipped in refrigerator cars to the East, to be disposed of by commission merchants and retailers, deteriorated in marked degree, that from full-drawn poultry in the greatest measure. The explanation is to be found in the contamination of the poultry in the process of evisceration and the subsequent multiplication of bacteria, with coördinate chemical changes in the tissues. Drs. Warfield T. Longcope and J. V. Cooke presented a communication entitled "A Case of Leukemia with Special Reference to the Enzymes in the Leucocytes." The case was one of acute type, the blood containing leucocytes with large nuclei. These were found to possess proteolytic and fat-splitting activity. Dr. H. H. Donaldson presented a communication entitled "Some of the Effects of Underfeeding in the Growth of the Brain." He had found in white mice that there was a lessened increase of weight including the brain, with, however, an orderly development of the myelin sheath of the medullated nerves.

Medicolegal Notes.

Requirements of Hypothetical Question.—A hypothetical question should contain all the facts essential to the expression of an intelligent opinion by the expert and of which there is evidence and not a partial statement of the facts which could not present the entire matter to the witness, so as to enable him to give such an opinion as the law permits to be considered by the jury.—Long vs. Austin, North Carolina Supreme Court, 69 S. E. 500.

Relative Value of Expert Testimony.—In an action for injuries sustained in a buggy accident it was held that the evidence of a physician who has attended a person immediately after an accident is of more weight on the question of the seriousness of the injury than that of the physician who has attended the injured person a year after the accident, for other causes and conditions may have intervened during the year.—Rickerson v. Town of Meriden, Louisiana Supreme Court, 53 So. 667.

Medical Services to Physician's Mother Not Necessarily Gratuitous.—A claim was made by the daughter of a deceased widow on the latter's estate for professional services rendered by the plaintiff to her mother in the plaintiff's capacity as a practicing physician. The plaintiff did not live with her mother, who, though possessed of enough means for her own support was supported by her daughters. She sustained a fracture of an arm for which the plaintiff rendered surgical assistance. While the decedent was on a visit to the plaintiff she was taken seriously ill, and was under the plaintiff's care for five weeks, until her death. It was held that under these circumstances there was no presumption that the plaintiff's services were to be rendered gratuitously in the absence of an express agreement to that effect, and that he was entitled to recover therefor.—*In re* Parker's Estate, 126 N. Y. Supp.

Physicians' Prescriptions Required under Statute by Druggist Are Not "Private Documents."—The written prescriptions of practicing physicians on which a licensed druggist has made sales of intoxicating liquors, and which he has preserved in his possession, as the statute directs, are not his "private papers and documents" within the meaning of the constitutional guaranty against compulsory self-crimination. Such prescriptions are quasi "public documents," and the constitutional privilege is not violated by compelling a druggist, who stands indicted for unlawfully selling spirituous liquors, to produce them in court in order that they may be used against him on his trial. A licensed druggist cannot sell intoxicating liquor to a practicing physician in West Virginia, except upon the written prescription of a practicing physician in good standing in his profession and not of intemperate habits. Such prescription must state substantially the following facts: (1) The name of the person for whom prescribed; (2) the kind and quantity of liquor; (3) that it is absolutely necessary as a medicine for such person; and (4) that it is not to be used as a beverage. A written order addressed to licensed druggist and signed by a practicing physician in the following words: "Send me OJ spts. whiskey and oblige," is not a lawful prescription for intoxicating liquor, and a sale made thereon is unlawful. When a sale of intoxicating liquors is proved to have been made by a licensed druggist, it is presumed to have been unlawfully made, and the burden is then cast upon him to rebut such presumption.—State v. Davis, West Virginia Court of Appeals, 69 S. E. 639.

Street Railroad Company Liable to Physician for Operation on Injured Person Irrespective of Its Liability to Latter.—While a street car was running between Trenton and Princeton, N. J., a flock of guinea hens ran across the track. The motorman, in leaning out of the car to see if any of the fowls had got into the running gear of his car, was knocked off, and the wheels of the car passed over his left leg between the knee and thigh. The conductor ran the car as fast as he could to Princeton and telephoned for a physician. Shortly afterwards the plaintiff arrived and administered to the injured man, tourniqueting the wounded leg and applying restoratives. The car was then run as fast as possible to McKinley Hospital, Trenton, as the plaintiff considered it necessary to get the man there to amputate his leg as quickly as possible. The plaintiff amputated the leg as soon as he arrived at the hospital. In an action by the plaintiff against the street railroad company for his fees a printed book of instructions issued by the company to its motormen and conductors was put in evidence which contained a rule requiring the conductor of a car in case an

accident should occur to take the injured person to a physician. It was held that the company was liable on contract to the physician for his services. Contributory negligence of the injured person, had there been any, would not have affected the company's liability.—Perkins v. Trenton St. Ry. Co., New Jersey Supreme Court, 78 Atl. 666.

Malpractice—Action in Tort—Degree of Care—Expert Opinion Admissible.—In an action by an infant against a physician for malpractice in treating and setting a broken arm (a compound fracture of the forearm) resulting, it was alleged, in the loss of the arm, it was held that such an action may be either *ex contractu* or *ex delicto,* and when it is *ex delicto* the allegations of the complaint as to a contract are mere matters of inducement and to show the relation between the parties and that there was a breach of duty based on or growing out of the contractual relations between the parties. Such an action need not be based upon a contract, though it may be and usually is. It is sufficient if based upon his legal obligation. The action for malpractice is essentially in tort, and hence it is immaterial by whom the physician is employed.

The reasonable and ordinary care, skill, and diligence which the law requires of physicians and surgeons is such as physicians and surgeons in the same general neighborhood, in the same general line of practice, ordinarily have and exercise in a like case. It was held that there was no error in allowing the question to be propounded to a medical expert whether it was reasonable prudence on the part of a surgeon setting a broken limb to leave the patient for ten days without any one trained in treating wounds, and with instructions to his parents that he need not be sent for unless the hand turned black. This did not substitute the witness for the jury; it merely afforded them the benefit of an expert's opinion as to whether that kind of treatment was reasonable prudence. —Carpenter v. Walker, Alabama Supreme Court, 54 So. 60.

Is a Person Liable for Payment of Fees of Operation on His Brother?—A physician and surgeon brought an action against two brothers for his professional services in performing an operation for appendicitis on one of the brothers. The action as against the patient was discontinued. The plaintiff claimed that the defendant requested a physician to employ another to operate upon his brother, who was then lying sick in the city of Pawtucket; that the defendant made arrangements to have the patient removed to a hospital in Providence, where he was operated on by the plaintiff. The patient was a man of 29 or 30 years of age, *sui juris,* and keeping house in Pawtucket with his wife and three children, while the defendant was a resident of Providence.

There was no denial that the work was performed, or that the sum sued for was the proper charge. The sole issue was whether the defendant was responsible for the services rendered to his brother. The question of to whom credit was given being in issue, it was held that the physician's books of account were inadmissible to charge the defendant for the services. Evidence as to other contracts or payments made by the defendant, as, for example, who paid the nurse for her services rendered to the patient, or whether the defendant engaged or paid for the hospital wherein the operation was performed by the plaintiff, was also inadmissible. These were *res inter alios acta,* and were properly excluded.

It was held that in order to recover, the plaintiff must prove by fair preponderance of the testimony, first, that the defendant requested the work, and, second, that he promised to pay for it, or some circumstance by which a promise could be implied from the request. There was no express promise, so that recovery, if any, must be on an implied promise. "If a husband calls a physician to attend his wife, being under obligation to take care of his wife, the law would imply a promise to pay for those services, even though he made no promise. If a father calls a physician to attend his minor son, he being under obligation to take care of that minor son, the law would imply a promise to pay for those services. But where a mere stranger—and brothers are strangers in that respect—calls upon a physician to attend a third person, whom the man calling the physician is under no obligation to take care of, then the law will not imply any promise to pay for the services rendered that third person, for they are of no benefit to the person making the request. In other words, the physician must look to the one for whose benefit those services are performed." On these facts the court directed the jury to return a verdict for the defendant.—Churchill v. Hebden, Rhode Island Supreme Court, 78 Atl. 337.

THE VACCINE TREATMENT OF TYPHOID FEVER.

By W. H. WATTERS, A.M., M.D.,

BOSTON, MASS.,

PROFESSOR OF PATHOLOGY, BOSTON UNIVERSITY; PATHOLOGIST MASSACHUSETTS HOMEOPATHIC HOSPITAL,

AND

C. A. EATON, M.D.,

BOSTON, MASS.,

LECTURER IN PATHOLOGY, BOSTON UNIVERSITY AND ASSISTANT PATHOLOGIST, MASSACHUSETTS HOMEOPATHIC HOSPITAL.

In the Medical Record, January 16, 1909, the writers presented a preliminary report of their results in the vaccine treatment of typhoid fever. It was there noted that the work was first begun in 1907 and was established as a routine method of treatment in various medical services in 1908. This was, therefore, as far as we are aware, the first instance of such routine measures being employed in any institution, as at that time there was a practically unanimous opinion in opposition to it, or at least a strong skepticism concerning its possible value. Richardson[1] had already experimented widely with various products of the typhoid organism, reporting to the Massachusetts Medical Society in June, 1907, his results from the use of antityphoid serum, of typhoid filtrate and of a nontoxic typhoid residue prepared by Vaughn of Ann Arbor. His results with these products were not particularly encouraging, except for his conclusion that relapses could be much reduced or eliminated. The same author in a later communication[2] adds to his list of cases treated by nontoxic residue, reporting a total of forty cases with but 5 per cent. of relapses. Richardson has used the same nontoxic residue in another series of twenty-eight cases[3] with a relapse percentage of less than five. Except for this, however, he says the results were largely negative. The use of this preparation is, accordingly, not very promising for the future.

Chantemesse[4] has by the use of his antityphoid serum made the most extensive tests of the specific therapy of typhoid. He reports 1,000 cases with a mortality of but 4.3 per cent. Wright has pointed out that this is more nearly a vaccine than an antiserum procedure.

During the years 1907-8 we first prepared and administered regularly vaccines to thirty-four cases of typhoid. The cases were not selected, all those coming into the medical services of Drs. E. E. Allen and J. H. Moore being taken. These have already been described in detail[5] [6]. Two deaths were recorded, one a patient practically moribund after nine weeks' sickness when treatment was begun. In comparing the clinical course of the disease in those treated with vaccines with a series of others in the same institutions and under the same general care and treatment other than vaccines, we made the following summary in a recent annual report to the hospital: "During the existence of this department there have been in the hospital approximately 140 typhoid patients. Some of these have received vaccines sporadically, late in the course of the disease, in a relapse, or for some reason or other the treatment has not been regularly given. Excluding such there have been thirty-six persons who received the regular vaccine treatment in addition to the routine methods. At the same time there have been seventy-one who have not received it. A study of these resulted in the following figures: Average duration of fever—Untreated, 25.3 days; treated, 15.5 days. Average residence in hospital—Untreated, 57 days; treated, 39 days. Percentage of reinfections—Untreated, 25; treated, 9.1. Average gain by those treated—In duration of fever, 9 days; in residence in hospital, 18 days; in relapses, 15.9 per cent."

Shortly after our preliminary paper Smallman[7] reported thirty-six cases with three deaths, and Semple[8] nine cases without any deaths. A number of others have more recently contributed to the list, a complete summary of which will be given below.

The object of the present paper is to report our results during a more recent period with the intention of endeavoring to demonstrate the validity of our earlier claim that not only are vaccines innocuous, when properly used, but that their use confers distinct benefit upon the patients, reducing the mortality, shortening the duration of the disease, and rendering relapse less liable. During the year 1910 all typhoid patients in the medical service of Dr. E. E. Allen received the vaccines as routine, while others were treated that were under the direction of Dr. N. M. Wood and Dr. J. P. Sutherland. We also cooperated in the treatment of nine cases in the Worcester City Hospital by Dr. O. F. Simons, and in the Kings Park State Hospital, Long Island, N. Y., by Drs. Leahy and Martin. During the entire year there has been no death from the disease among those receiving vaccines, either in our own institution under our personal observation or in any instance where others administered the treatment according to our suggestions. This is in contrast to a mortality of 20 per cent. among those not vaccinated.

In all thirty-five cases are reported. A brief synopsis of any unusual features of each case is appended to the accompanying temperature charts. These charts are given in order that each reader may judge the effect of the vaccines upon the course of the disease. No aggravation or injury of any kind was demonstrable as a result of any inoculation. As may be seen there has been a tendency to decrease the size of the dosage rather than to increase it, particularly in making the second and subsequent inoculations somewhat smaller than the

first. The more serious the clinical conditions of the patient the smaller the dose employed. This was apparently well borne out in one case that was considered to be all but hopeless. Here daily doses of one or two million bacilli were followed by gradual change for the better in the clinical symptoms.

In concluding this part of the paper we may not inappropriately summarize the reports of results thus far obtained by various workers.

Author.	Cases.	Deaths.	Relapse

*Whether these cases be classed as vaccine treated or not may be considered as open to question, dependent upon our conception of the relation between non-toxic residue and vaccines.

Case I.—L. A. Patient of Dr. L. A. Brown. This old lady had been sick for about ten days in an adjoining State. The condition was practically stationary and showed the usual symptoms in the

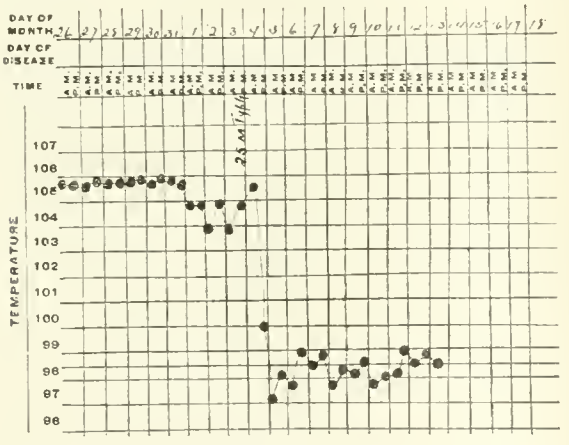

Chart of Case 1.

second week. Widal reaction positive. Following a single inoculation the temperature fell by crisis and convalescence was steady and uninterrupted.

Case II.—W. W. Patient of Dr. O. F. Simonds. On October 10 positive Widal was present. On the 19th one inoculation with vaccine was given, a date

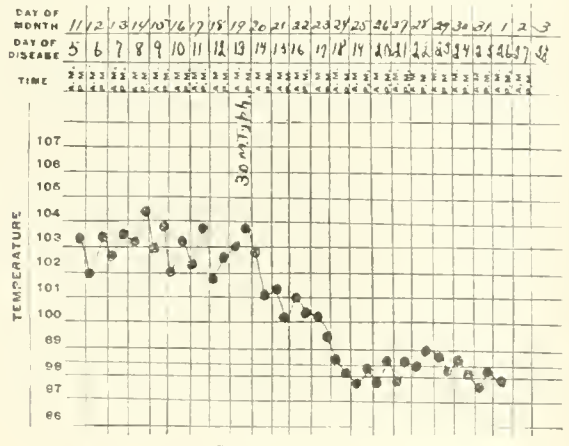

Chart of Case 2.

corresponding to the thirteenth day of the disease. The headaches, nausea, and vomiting, which had been severe for several days, gradually subsided until they completely disappeared on the 23d. Convalescence uninterrupted.

Case III.—Patient of Dr. W. H. Kennison. A man about fifty-five years of age, showing a gradually increasing temperature for about ten days, together with epistaxis, headache, diarrhea, and positive Widal. The heart was in a weak condition and caused considerable anxiety. Following a single inoculation the gradually increasing temperature was changed to a gradually decreasing one and in less than one week reached normal, where it remained thereafter.

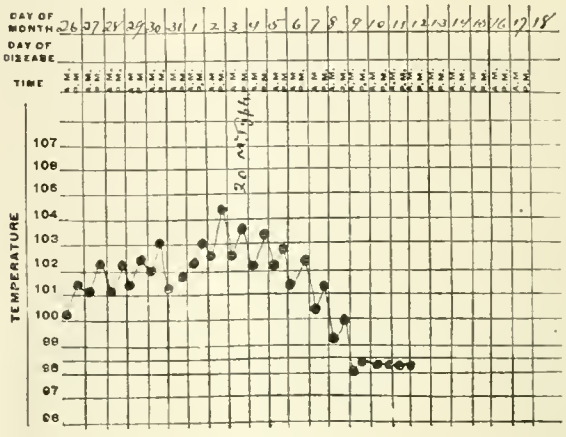

Chart of Case 3.

Case IV.—G. T. Had been sick about a week prior to admission. The usual symptoms of typhoid fever to a severe degree, including positive Widal. Following a single inoculation the temperature gradually fell and with it all the various symptoms subsided.

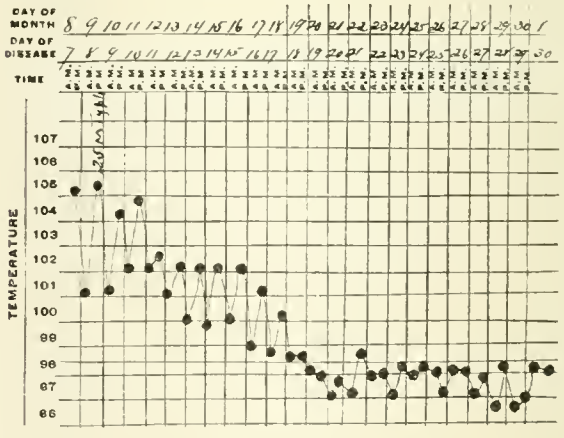

Chart of Case 4.

Case V.—Miss C. T. Sick about one week prior to admission. Temperature had been gradually rising. During this time there had been a gradual increase of symptoms, such as headache, backache, and diarrhea. Widal reaction positive. Following inoculation temperature gradually fell to normal without clinical complications.

Case VI.—J. L. Boy about fourteen years of age. When admitted to the hospital had been sick for about a week. Was delirious and had to be kept under restraint. Marked twitching of the hands and certain muscles of the face was present. Within about twelve hours after the first inocula-

tion the symptoms began to subside and disappeared with comparative rapidity after the second one.

Case VII. Miss K. P. was compelled to take to her bed about ten days prior to admission. At

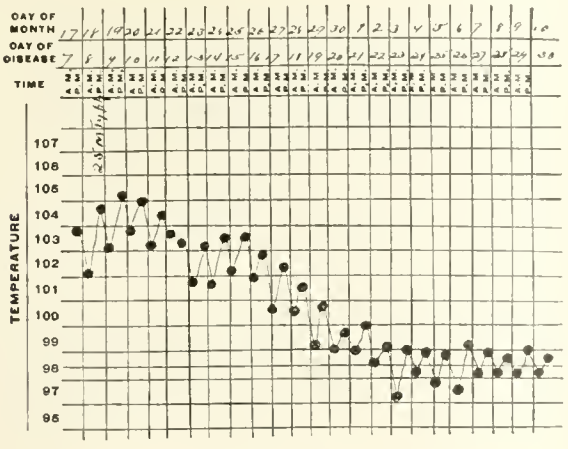

Chart of Case 5.

the time of admission she showed a positive Widal and the usual symptoms of a mild typhoid fever. Following the single inoculation temperature gradu-

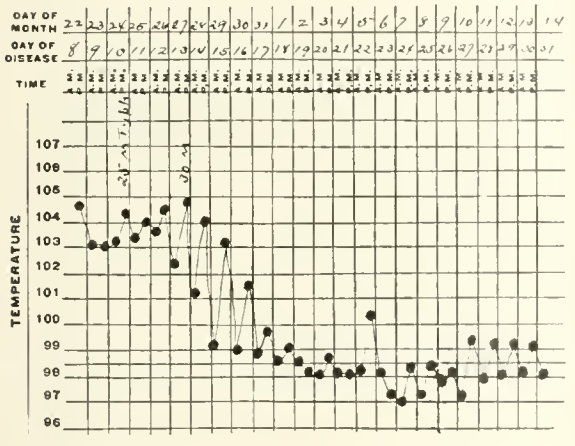

Chart of Case 6.

ally began to subside and the symptoms to disappear in a corresponding manner.

Case VIII. Patient of Dr. Leahy. Had been sick for about two weeks with a somewhat irregular

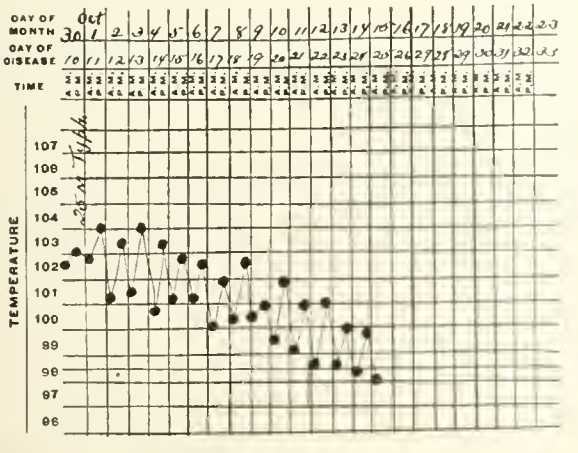

Chart of Case 7.

type of fever clinically corresponding to a moderately severe typhoid infection; also showing positive Widal. Two inoculations were given, which were followed by distinct amelioration of all symptoms and a rapid convalescence.

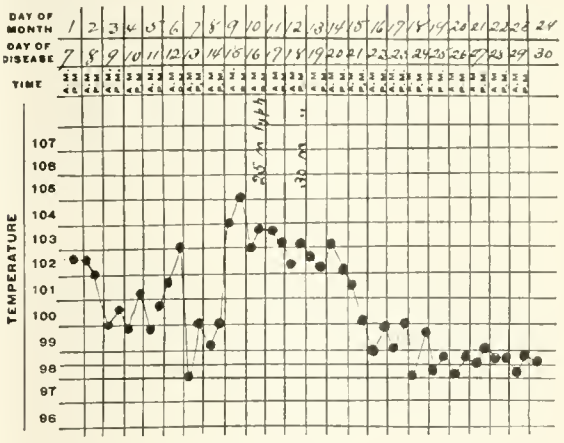

Chart of Case 8.

Case IX. Reported by Dr. O. F. Simonds. On October 20 a positive Widal was obtained. Considerable abdominal pain was present, accompanied by constipation and rose spots, headache, and some nausea. It is interesting to note the decline of fever which was accompanied by a corresponding decline of the various symptoms following each inoculation. The convalescence was uninterrupted.

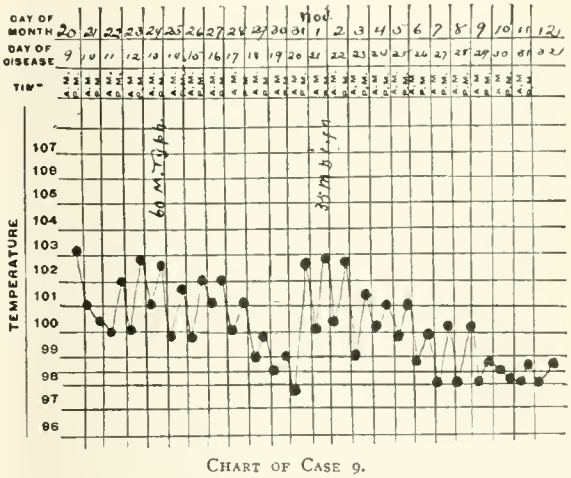

Chart of Case 9.

Case X. J. B. Patient of Dr. Leahy. At the time of the first inoculation duration of fever had been about nine days. For about three days following the first inoculation symptoms of pulmonary congestion appeared which rapidly subsided, as did also the various symptoms of the original disease.

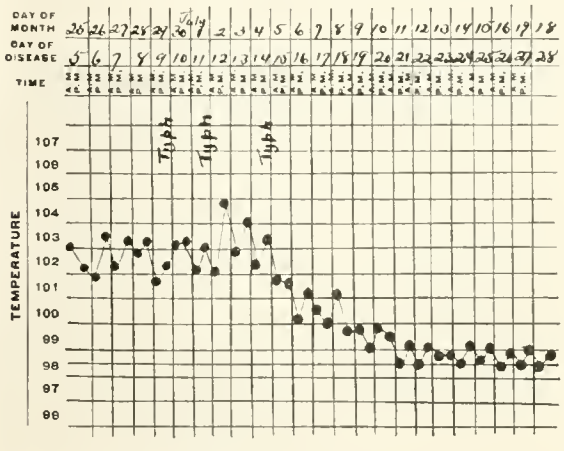

Chart of Case 10.

Case XI. Miss H. H. A young lady who presumably became infected in Naples. The fever appeared during the voyage to Boston. When admitted to the hospital she was in a highly nervous state, showed a positive Widal reaction, rose spots, and severe headache. Prognosis at that time seemed very unfavorable. Following administration of vaccines the symptoms began to improve and showed even greater relative improvement than did the corresponding decline in fever. The convalescence was most satisfactory.

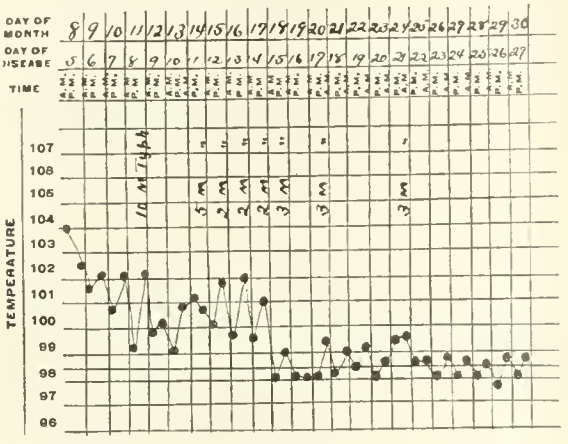

Chart of Case 11.

Case XII. E. A. This man had been treated for a primary attack of typhoid, as stated, about six weeks ago in another hospital. On August 29, when admitted, showed the usual signs of a moderately severe case of typhoid. These various symptoms gradually subsided in a manner corresponding to the fall in temperature.

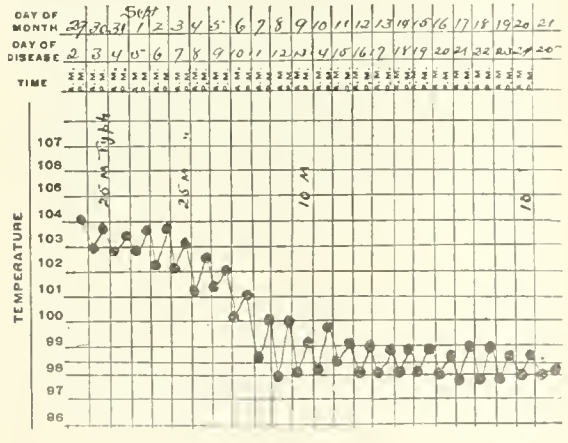

Chart of Case 12.

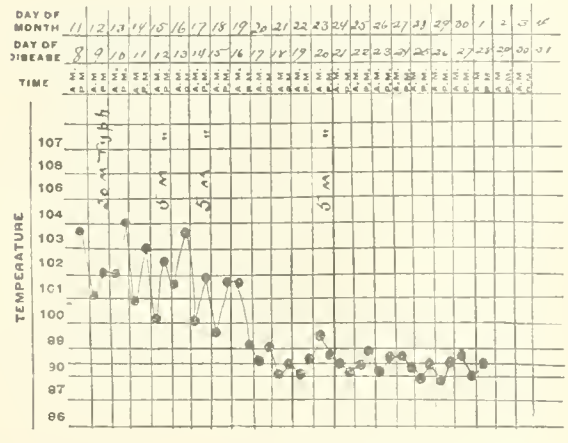

Chart of Case 13.

Case XIII. R. L. A child about five years of age. Positive Widal, headache, backache, and mild diarrhea. The temperature chart forms a very satisfactory indication of the course of the symptoms following admission.

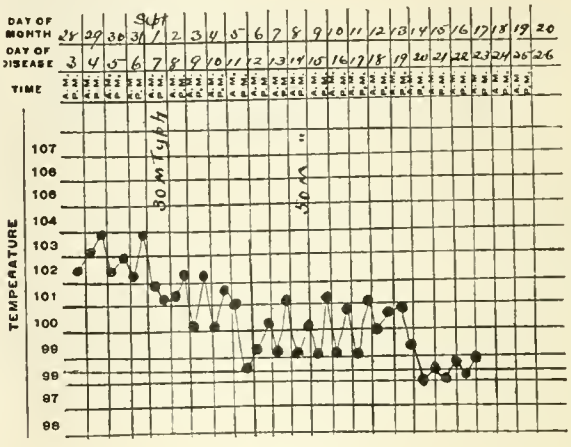

Chart of Case 14.

Case XIV. Patient of Dr. O. F. Simonds. A mild case of typhoid that showed a positive Widal on October 30. Temperature began to decline immediately after the first inoculation. Convalescence quite satisfactory.

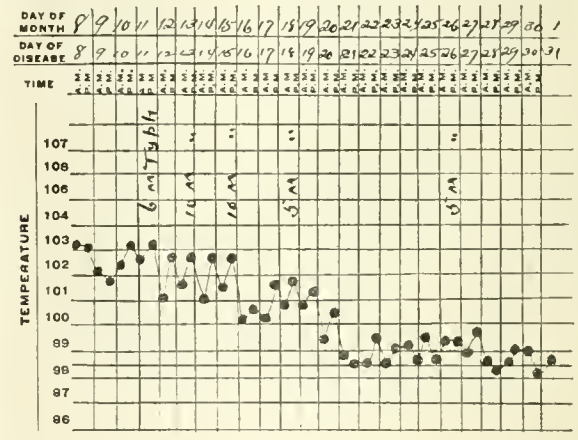

Chart of Case 15.

Case XV. E. B. A child six years of age. The ordinary symptoms of typhoid of moderate severity present. First treatment was given on the eleventh day of the disease. Previous to this time the temperature had remained about stationary. Following this it began to fall, reaching normal on the twenty-second day, with a correspondingly satisfactory convalescence.

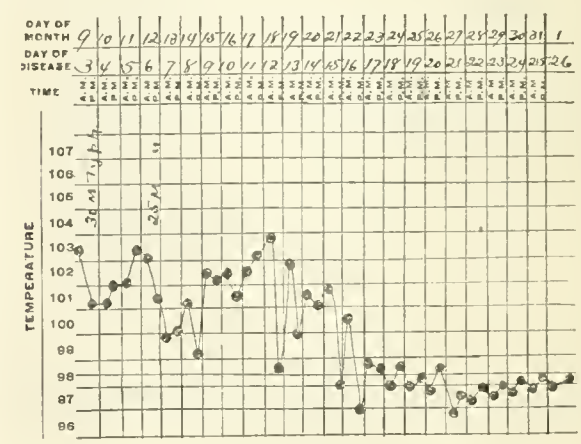

Chart of Case 16.

Case XVI. H. K. Patient of Dr. T. B. Foley. A nurse. Went to bed October 7 suffering from intense frontal headache, nausea, and vomiting. Spleen was enlarged and tender. Tenderness in the ileocaecal region. Positive Widal. Thirty-six hours after the first inoculation temperature fell to 97°. At midnight a slight chilliness, but with no symptoms of hemorrhage or perforation. Patient felt well thereafter.

Case XVII. R. M. Boy about eight years of age. For about three days following admission he was acutely delirious and required restraint. This gradually disappeared and he became more quiet, gradually recovering to a rather early convalescence. Persistent normal temperature on the twenty-fourth day.

Case XVIII. A. W. Patient of Dr. O. F. Simonds. On October 12 showed a positive Widal. Coated, tremulous tongue. Gurgling on right side of abdomen, frequent vomiting. Following inoculations the symptoms gradually disappeared. A somewhat higher temperature for one day was apparently due to an otitis media which rapidly disappeared the next day.

Case XIX. A. Z. Patient of Dr. O. F. Simonds. This man was treated for lobar pneumonia during the last week of October. Pulmonary symptoms cleared up on November 1. Showed a positive Widal reaction with corresponding signs of typhoid. Two inoculations seemed to be folowed by satisfactory convalescence.

Case XX. R. McD. This man showed a positive Widal, rose spots, abdominal gurgling, mild headache, slight diarrhea. A single inoculation was given. Clinical symptoms mild throughout and rapidly disappeared after the inoculation. Duration of fever seven days.

Case XXI. Miss M. S. This young lady had been sick about eight days prior to admission with a mild febrile condition corresponding clinically to typhoid. Widal reaction positive. A single inoculation was given, followed by amelioration of symptoms and a decline of temperature which reached normal in five days.

Case XXII. B. D. Patient of Dr. O. F. Simonds. This was a case of relapse occurring nine days after discharge from the hospital in a patient not previously treated with vaccines. Each of the two inoculations given was followed by distinct fall in the degree of fever, the second fall being a permanent one. Convalescence uninterrupted.

Case XXIII. W. R. Reported by Dr. O. F. Simonds. A nurse. On October 12 showed a positive Widal. Temperature varied from 99° to 101° until October 14, when the first inoculation was given. This did not apparently have much effect upon the temperature, a second and larger inoculation given on October 23 being followed by distinct drop in the degree of fever. Patient was comfortable and rational throughout the entire course of the disease, complaining very little of any disturbance. No fever after the twenty-fourth day.

Case XXIV. M. R. A very mild case of typhoid. Characterized by almost complete absence of symptoms after the first inoculation was given. Following this inoculation the temperature reached 100° only twice throughout the entire course of the disease.

Case XXV. Miss I. O. This young lady showed much more severe clinical symptoms than the temperature would seem to indicate. Following each inoculation there was a distinct fall in the degree of fever, reaching normal for two successive days on four different occasions. The fourth fall proved to be permanent. Smaller doses were given here than in many of the other cases.

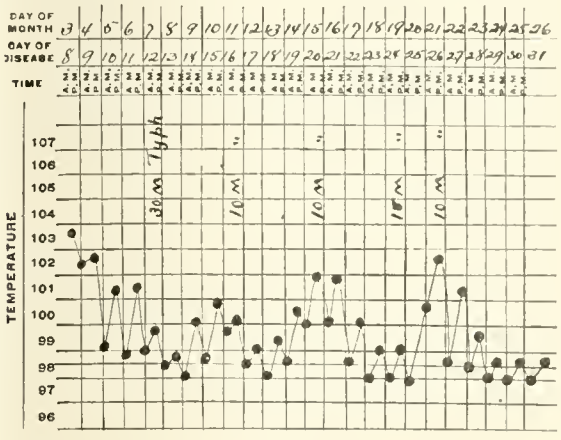

Chart of Case 25.

Case XXVI. R. H. When the first inoculation was administered this man had been sick only two weeks. He showed a temperature steadily maintained at about 103° to 104°. Mental condition was one of semistupor, apparently indicative of a profound toxemia. Inoculations repeated about every fourth day were followed by a gradual decline in temperature and a more rapid disappearance of unfavorable symptoms. When first treated the prognosis was very grave. Convalescence uninterrupted.

Case XXVII. Mrs. E. L. This woman was in a state of profound toxamia when first seen on the ninth day of the disease. Temperature varied between 101° and 103° and was accompanied by a low, muttering delirium. On the nineteenth day after her admission to the hospital she had a severe hemorrhage and was in a very critical condition for two or three days thereafter. This hemorrhage did not seem to show any distinct relation to the inoculations, a small one of 10,000,000 having been given two days prior to its occurrence. The hemorrhage was accompanied by a sudden drop in temperature to 96.8°; it then reached 103.8° the same day, gradually falling to about 100° in two days, where it remained for a short time, then gradually fell to normal. Convalescence rather slow, but otherwise uneventful.

Case XXVIII. Miss A. J. Patient of Dr. O. F. Simonds. This woman had been sick for two weeks prior to admission to the hospital. When admitted she was suffering from a severe diarrhea, headache, and abdominal pain. Tongue very dry, coated and tremulous. There were a moderate amount of general abdominal tenderness and some rose spots. The Widal reaction was positive. First inoculation given on the seventeenth day of the disease. This was repeated on the twenty-second, twenty-fifth, twenty-eighth, thirty-fifth and thirty-ninth. Temperature reached normal on the forty-fifth day and remained there thereafter. For about ten days there was general typhoid decubitus, loss of control of the sphincters, and muttering delirium. During this time the patient was placed upon the dangerous list and was supposed to be in a hopeless condition. Convalescence was slow.

Case XXIX. W. L. This boy received one inoculation on the sixth day of the disease, after the

temperature had been for several days between 103° and 104°. It was followed by an immediate decline in temperature of about 2°. A second inoculation on the eleventh day was followed by a still further decline to normal on the sixteenth day. All clinical symptoms disappeared and remained absent for eight days. Then the temperature gradually rose for four days, reaching a maximum of 103°. A single inoculation at this time was followed by a steady decline in the fever, which entirely disappeared six days later. The recrudescence of the disease, as indicated by the temperature, was not accompanied by a corresponding appearance of the clinical symptoms.

Case XXX. J. S. Reported by Dr. O. F. Simonds. Two inoculations were given to this patient, one on the tenth day of the disease the other on the twenty-seventh Febrile condition persisted for twenty-eight days, the last twenty-five of which the temperature was seldom above 100°. Clinical symptoms comparatively slight.

Case XXXI. Mrs. M. W. This patient received four inoculations, on the eighth, tenth, thirteenth, and sixteenth days of the disease, with no clinical evidence of effect in any way. The disease ran a quite typical course for an ordinary case of typhoid. No inoculations were given later than those mentioned above. After an interval of apparently complete convalescence the temperature once more gradually began to ascend and persisted at about 102° to 104° for nearly a week. Two further inoculations were here given and these were followed by a gradual subsidence of all symptoms and by complete convalescence.

Case XXXII. E. W. A young man treated by a physician at a distance from Boston and where frequent reports could not well be sent. The dosage in this case was much smaller than that usually recommended and did not apparently influence the patient to any marked degree, except a final dose of about 20,000,000, which was followed by a sudden decline in temperature from 103° to 96°. After reaching this low point the symptoms steadily improved. The temperature did not at any time thereafter reach 100°, remaining practically normal.

Case XXXIII. Mrs. C. G. B. A case of typhoid complicated by an acute nephritis. First inoculation on the tenth day was followed by a gradual decline in temperature, which was continued after the second inoculation on the fourteenth day. The inoculation on the eighteenth day was followed by a slight rise of temperature during the next twenty-four hours. Each inoculation was followed by distinct clinical improvement. Apparently in this case the duration of the fever was not materially shortened, although the clinical symptoms were apparently distinctly benefited.

Case XXXIV. W. P. This man showed a condition of great prostration, persistent high temperature, low muttering delirium and other indications of a marked degree of toxemia. He was supposed to be in a practically hopeless state, the prognosis being very grave. First inoculation was given on the fourteenth day. Inoculations were given at intervals of from one to four days over a period of three weeks and were followed by an amelioration of all the various symptoms, at first very slow, later more rapid. Convalescence occurred without complications.

Case XXXV. L. B. This patient was treated in a distant hospital in the State. On account of a misconception of the directions given, the dosage was about one-fifth of that intended. There was, therefore, no clinical improvement demonstrable from the treatment. The man was very sick and made a slow and steady convalescence.

FIBRILLATION OF THE AURICLE.*

By LOUIS FAUGÈRES BISHOP, A.M., M.D.,

NEW YORK.

CLINICAL PROFESSOR OF HEART AND CIRCULATORY DISEASES, FORDHAM UNIVERSITY SCHOOL OF MEDICINE, NEW YORK CITY; PHYSICIAN TO THE LINCOLN HOSPITAL.

We are indebted to laboratory experimentation in pathological physiology for clearer views on many points in cardiac disease. In most instances this has been merely a clarification of ideas that already existed, so that it is not easy to define any particular point for which we are entirely indebted to this work.

Our information of fibrillation of the auricle comes as near as anything to being entirely dependent upon laboratory observation. It has been a familiar observation in physiological experimentation on animals that death of the heart is preceded by a condition of delirium cordis in which there seemed to be a great number of irregular contractions of various fibers, without any efficient contractions of the auricle or ventricle.

The clinical importance of this familiar observation was not known until quite recently, but it is found that under certain conditions the auricle alone may be involved in this remarkable form of muscular activity to which the name "fibrillation" has been given, and it was observed that when this happened the action of the ventricle caused an arterial pulsation very closely resembling the irregularity found in many patients suffering from a temporary breakdown of the heart, and also in many cases of persistent irregularity of the pulse. This, with the study of polygraph tracings, has led to the conclusion that fibrillation of the auricle is a fairly frequent clinical phenomena. In a brilliant course of lectures delivered by Dr. Cushny this winter in New York, he made the statement that this condition existed in upward of one-half of the serious heart cases admitted to hospital wards.

The fibrillating auricle transmits to the ventricle a large number of impulses. The auricle, of course, can only respond to a few of these, and when it has responded it becomes refractory to impulses for a

*Read before the Bronx Medical Association, March 23, 1911, at the Lincoln Hospital.

certain length of time. However, it responds to the next impulse that happens to strike it after the refractory period is recovered from. This very beautifully accounts for the fact that though there are a great number of irregular contractions of the auricle transmitted to the ventricle, yet the ventricle contracts only a relatively moderate number of times and very irregularly. The effect of digitalis is to increase the tonicity of the ventricle and so steady it, and also create a partial heart block which delays and cuts off some of the many impulses from the auricle. Hence the wonderful efficiency of digitalis in cardiac breakdown of this type. When this incoordinate or vermicular action of the cardiac muscle bundles occurs in the ventricle, the ventricle stops, and there only remains this trembling action of the muscle bundles; the ventricle does not empty itself, and is therefore useless as an organ of circulation.

It seems probable that some cases of sudden death are really fibrillation of the ventricle, rather than true asystole. Very large doses of digitalis may cause fibrillation of the ventricle, instead of the picture of tonic contraction that we have always carried in our minds, as apparent in death from digitalis poisoning. The heart can still carry on its work, though in a poor manner, when the auricle is paralyzed, but a fibrillating auricle causes great irregularity of the ventricle. What amounts to definite knowledge of fibrillation only dates back a year or two, and is not yet known to the general profession. However, when it is once recognized and its true nature understood, its existence will, I am sure, be immediately accepted, and all will explain very clearly what is happening in many cases of irregular heart that have been very obscure in the past.

The polygraph tracings in these cases are quite characteristic, but like all venous pulse tracings they are difficult to understand until after one has given a good deal of attention to them. We always thought in these cases that we had failed to get a good venous tracing because it was so hard to analyze the curve, but now we know the reason we did not find the A (auricular) wave was that it did not exist. What impresses one in looking at these venous curves is the striking similarity to the radial curve which is entirely at variance with a normal case, so a good name for it is the "ventricular type of venous pulse," the auricle being practically inactive; the only impulse transmitted to the vein is that from the ventricle, and naturally the prominent wave falls at the same time as the ventricular contraction, while, of course, the A wave or auricle wave in the normal jugular pulse comes before the ventricular contraction. However, in many cases a great number of small waves have been observed, amounting from 400 to 900 in a minute, corresponding to the same waves that can be obtained in the case of an animal in which this condition of fibrillation of the auricle has been reproduced. Dr. Cushny told of a very remarkable confirmation of this theory which was attained in the case of a horse which was afflicted with the clinical signs of fibrillation of the auricle. As you know, the heart action persists a short time after the death of the animal, when killed by some cause outside of the heart. This horse, which was afflicted with an irregular heart corresponding to that of a human being, was shot, after due preparation, and the heart was rapidly exposed and examined, and sure enough this condition of fibrillation of the auricle with an irregular ventricular action was directly observed.

Digitalis has no effect upon the auricle except that it may render the fibrillation finer. Its benefit, as already pointed out, exists in its effect upon the bundle of His and other transmitting structures, and upon the tonicity of the ventricle. It is often said that these very abstruse methods of examination into heart disease only belong to the domain of the specialist. It is absolutely true that no one in general practice could take the time to study cardiac arrhythmias very closely, fibrillation of the auricle being only one side of the subject. However, when the cases have been studied by the specialist and pointed out, they are not so hard to discover, though, of course, the diagnosis must be definitely confirmed by someone of wider experience. When, however, we realize that fibrillation exists in more than one-half of all the very serious hospital cases presenting an irregular pulse, together with symptoms of heart failure, dropsy, shortness of breath, and tenderness over the liver, and when it is realized that this is about the only disease which causes absolute irregularity, it can be seen that it is not so difficult to discover. In some cases the sphygmograph is enough. If a tracing of a pulse shows absolute irregularity so that no two beats are alike and the beats never come at regular intervals, it may be assumed that it is a case of fibrillation of the auricle. In all the other irregularities there is some law discoverable with relation to the occurrence of the impulses, as they are very apt to occur in groups. For instance, in extra systole, which is perhaps the commonest form of irregularity, it is noticed that there is a beat interposed between the natural beats, followed by a correspondingly long pause of the heart, but the rhythm is resumed after this.

The following few simple points in the physiology of the heart I assume you are all familiar with, but they are worth recapitulating: In the normal heart action the contraction of the heart originates in the auricle and passes through the bundle of His to the ventricle, so that the auricle contracts and then the ventricle, the ventricular contraction depending upon the auricular impulse. However, the ventricle has the power of originating contractions of its own, but the natural contractions of the ventricle are much slower—perhaps thirty to the minute—than those which ordinarily originate in the auricle. It is also well to remember that the ventricle is the essential part of the heart, and that the circulation is carried on fairly well without the use of the auricle. If this were not so, patients with fibrillation would immediately succumb. Of course, the best proof of this independent ventricular contraction is found in Adams-Stokes disease, in which the transmission from the auricle to the ventricle is stopped. In such a case the ventricle beats independently of the auricle. Perhaps the most typical case on record is the one which happened in this hospital some years ago, and which was published in the *American Journal of Medical Sciences*, January, 1910. Also remember that the ventricle loses its power to contract immediately after it has contracted, and this power is only recovered after a certain interval; this is called the "refractory period." It is only on account of this property that the ventricle does not attempt to contract after all impulses that come from the fibrillating auricle. It only contracts to the first impulse that reaches it after it has recovered from its refractory period. So there is a limit to the number of contractions to which the healthy ventricle can respond, and the rest are lost.

So, to recapitulate, I should say, using very common language, that fibrillation of the auricle prac-

tically amounts to a trembling palsy of the heart—but a palsy that casts an influence over the healthy part of the heart. The healthy part of the heart is perfectly able and willing to contract regularly, but at a very slow rate. The paralyzed part of the heart is constantly lashing the healthy part of the heart into contractions, but when the heart has contracted once it will refuse to contract again until after it has had a rest, and then as soon as it is able to, it contracts to the next impulse. If we could cut the bundle of His in a case of fibrillation of the auricle, the heart would act regularly, but very slowly.

INTRAVESICAL IRRIGATION IN ACUTE GONORRHEA.

By MAX HÜHNER, M.D.,

NEW YORK,

CHIEF, GENITOURINARY DEPARTMENT, HARLEM HOSPITAL DISPENSARY.

In a paper published two years ago, I strongly advocated the intravesical irrigation treatment in acute gonorrhea even when only the anterior urethra was involved. Since then I have received so many inquiries from physicians, also from private conversation with medical friends, that I have come to the conclusion that some further remarks upon this important subject would not be amiss. Before, however, taking up the discussion of the theory of this method of treatment I would like to say a few words about an objection that has often been urged against treating *anterior* gonorrhea by it. I refer to the supposed danger of setting up a posterior urethritis.

It must be admitted that were this objection to hold it would absolutely debar the use of this method in anterior urethritis, for no matter what its advantages may be, this one disadvantage would outweigh any good that might come from it. In other words, if cases of anterior urethritis treated by the hand syringe method, or by irrigations up to the cut-off muscle, never, or very seldom, develop posterior urethritis, while cases treated by the intravesical irrigation method very often, or more often, develop it, this one fact would, to my mind, be sufficient reason to banish its use in gonorrhea of the anterior urethra, or, in other words, in every acute gonorrhea.

In the following pages I shall in explaining the technique and theory of intravesical irrigation, attempt to show not only why this method must of necessity actually prevent more cases of anterior urethritis from becoming posterior than any of the other methods, but also from the statistics of the very ones who oppose this method, that practically and clinically (which after all is the supreme test) this method yields results and causes less complications than do others.

First, as regards statistics. It is a noteworthy fact that those who are the severest critics of this method are the very ones who judge from theoretical knowledge rather than from practical experience and who, in many cases, admit that they have never used it. Thus, a medical friend of mine told me that he would sooner think of flying than use an intravesical irrigation in the presence of pus in the anterior urethra. Taylor,[2] who severely criticises this method, admits that he did not try it and says "I have it from the word of mouth of gentlemen who have been thus treated that in the manipulations necessary for flushing out the anterior urethra and filling the bladder some of the injection, as a rule, escapes and not only dampens but stains their linen," etc. Although admitting that he never tried it and obtained his information from patients, he nevertheless continues to discuss it and to state its drawbacks and disadvantages.

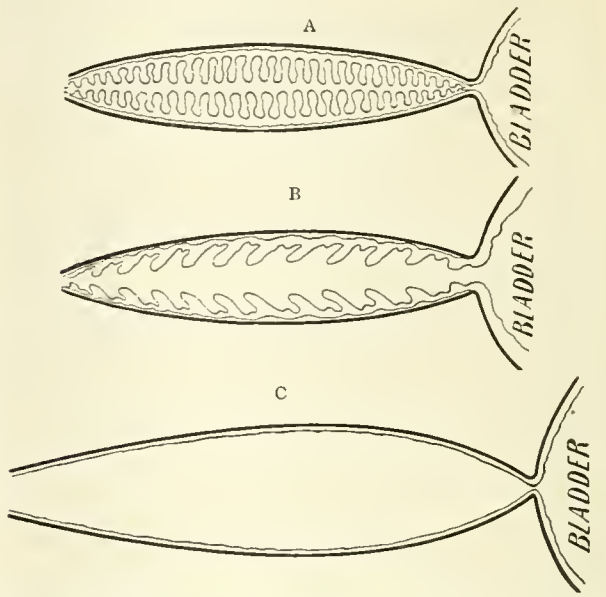

Fig. 1.—Diagrammatic scheme of the urethra: A. Urethra at rest. Mucous membrane thrown into numerous folds. Practically no urethral canal. B. Urethra during urination. Folds of mucous membrane not so numerous, but still present and not entirely obliterated. C. Urethra during erection. Entire urethra lengthened and mucous membrane stretched so that all folds are completely obliterated. Same condition exists during intravesical irrigation.

Those who have performed many intravesical irrigations and know that it can be carried out without either soiling the doctor or patient and without any discomfort whatsoever to the latter, must appreciate that those critics cannot talk of practical experience who write about using cocaine in order to overcome the pain of an irrigation. To quote from another prominent specialist[3]: "Many writers speak of forcing the compressor muscle by hydrostatic pressure. Of course, this can be done, but with what an amount of discomfort and injury to the patient," etc. Surely practical experience with this method could not dictate a statement like this. Or again[4]: "If, however, the posterior urethra

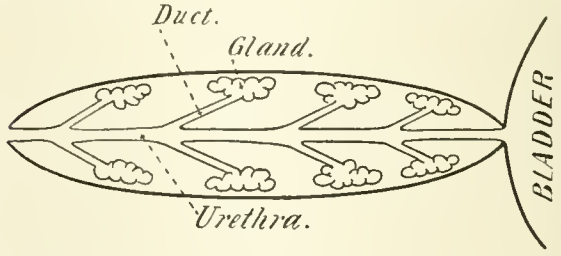

Fig. 2.—Diagrammatic scheme of the glands and ducts of the anterior urethra.

is also involved the irrigation must reach the bladder, where it is better to avoid spasm of the cut-off muscle by the use of cocaine, 10 to 15 grams of a 1 to 150 solution held in the anterior urethra for four or five minutes." As I shall show further on, a certain amount of spasm is not only not harmful but is actually beneficial, and one of the great advantages of this method comes from the necessary distension of the urethra due to the irrigating fluid trying to overcome the tonus of this muscle. I will quote just one more author[5] who in a recent article criticises this method as follows: "By its advocates

the irrigation method is credited with results equal to those of the hand-injection method. To my mind, however, the method is not as rational unless the medicament used be a silver albuminoid compound in weak solution and unless the irrigation be given so gently and skilfully as not to subject the sensitive, acutely inflamed urethra to the additional traumatism of overdistension, nor force the fluid past the sphincter into the bladder. The intentional carrying out of intravesical irrigations during acute urethritis is irrational and unwarranted. They cannot but lead to hyperemia of the mucus membrane of the deep urethra. This in turn invites infection. The dangers, as already mentioned, are urethrocystitis and epididymitis. The main utility of this method lies in the effect that moist heat has upon any inflammation." In discussing the theory of intravesical irrigations I shall show that the writer of the just quoted article misses the chief point of it, namely, the deliberate overdistension of the urethra with consequent unfolding of the folds of mucous membrane and thorough cleansing it of all its contents; also that those who have practical experience with the method do *not* cause epididymitis, urethrocystitis, etc., as the writer theoretically thinks they ought to cause. But more of this hereafter.

Let us now come back to statistics and see what results are obtained by those who criticise the intravesical method.

Of the older writers, Robert W. Taylor,[6] who, as we have previously mentioned, is one of the severest critics of intravesical irrigation, and who gives elaborate and detailed methods of treating acute gonorrhea, first by rest, and then by the hand syringe methods says (page 156): "It is now a well-established fact as we have seen in a previous chapter that anterior urethritis in between *80 and 90 per cent.* of cases within the early days of the infection passes backward and involves the posterior urethra." (Italics mine.) He then makes the very significant statement, to which I shall have occasion to refer later on, that the tonus of the constrictor muscle offers no impediment to the passage of the inflammation from the anterior to the posterior urethra.

Robert Holmes Greene[7] strongly condemns the intravesical treatment as exposing the patient to the dangers of posterior urethritis, prostatitis, etc. He treats his patients by the expectant method. He says: "The best treatment of acute urethritis, for the first six or eight weeks at least, is to refrain from local methods, leave it alone, etc." He remarks, however, that "urethritis not rarely but *generally* invades the deep urethra and prostate and not the anterior urethra alone." (Italics mine.)

Ramon Guiteras[8] says that "fully 80 to 90 per cent. of all attacks reach the posterior urethra."

Coming now down to very recent times we find exactly the same statistics. Leedham-Green[9] in his latest work (1908), after giving elaborate directions for treating the disease, ends by saying that "usually anterior urethritis becomes posterior at the end of the third week." He also quotes Jadassohn (1889) as obtaining posterior urethritis in 87.7 per cent, Rona in 90 per cent. and Finger in 63 per cent. in private practice and 82 per cent. in his hospital practice. None of them use the intravesical method. Hayden,[10] who is a strong advocate of the expectant plan of treatment, says that during the course of an acute anterior gonorrhea the inflammatory process *frequently* passes beyond the compressor muscle and becomes posterior. We thus see that those who most vigorously oppose the intravesical method and who lay stress on the fact that this method must expose the patient to the dangers of posterior urethritis, prostatis, etc., by their own statistics admit that they, by their own method, obtain these complications in 80, 90 and 100 per cent. of their cases. Surely the intravesical method cannot do much worse. I shall show later why it must of necessity obtain much better results.

Since the advent of the new silver salts it would seem that much improvement has been made in this direction. Thus Ludwig Weiss[11] says: "While acute posterior urethritis which is regarded as the most usual complication will develop into 70 to 80 per cent. of cases treated in the beginning with astringents, we will find it when employing the new silver salts only in 30 per cent., and according to some statistics in only 10 per cent. of cases." Frank,[12] speaking in 1900 before the Genitourinary section of the Thirteenth International Congress of Medicine, states that in 631 cases of acute gonorrheal urethritis the posterior urethra became involved in 32¼ per cent., nearly one-third of all the cases. Other very careful specialists did not, however, obtain even as good results as these. Thus White and Martin,[13] in their latest textbook, while extolling the new silver salts and not recommending the intravesical treatment,

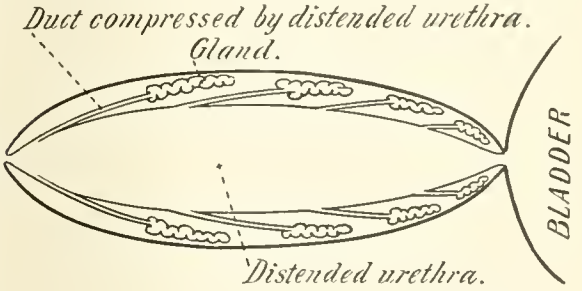

FIG. 3—Same as Fig. 2, with urethra distended.

say: "It may be assumed that in about 90 per cent. of all cases of gonorrhea the posterior urethra is involved in the inflammation." And only a little over one year ago Dr. J. Pedersen, in an article previously referred to in the *New York Medical Journal*, wherein, as we have seen, he severely criticises the intravesical method, and recommends the new silver salts, says that "posterior urethritis occurs in 90 per cent. of all cases of anterior urethritis."

Why is it, then, that so many prominent specialists using either the expectant or hand syringe method, obtain an involvement of the posterior urethra in between 70 and 90 per cent. of their cases? In order to answer this question it is necessary to have a clear idea of the anatomy of the urethra.

It stands to reason that if the urethra were a smooth glass tube, any ordinary irrigation or even the act of micturition would easily wash away any pus, etc., that may be therein. But this is not the case. The mucous membrane of the urethra is made up of numerous folds to allow for its distensibility when necessary, and it is between these folds and in the crypts and ducts that the pus and bacteria lodge. It necessarily follows that in order to dislodge them we must distend the urethra to make it resemble as near as possible a glass tube.

Now, the anterior urethra may be considered as a tube bounded in front by the meatus, in

back by the cut-off muscle, and its mucous membrane thrown into numerous folds and continuous with that of the posterior urethra. It is absolutely necessary to clearly understand the action of the cut-off muscle. Except during micturition, etc., it is in a state of tonic contraction, which, with the external sphincter, prevents fluids from the bladder and posterior urethra from entering the anterior urethra. It was formerly believed that the tonus of this muscle could prevent the spreading of inflammation from the anterior to the posterior uretha, but this theory has long since been disproved. Any rough instrumentation or irritating or cold injections will increase the tonus or spasm of this muscle, while gentle instrumentation, as the gentle passage of a small soft rubber catheter, or the gentle and continuous playing against it of a mild warm solution will cause the muscle to relax. White and Martin, in their latest edition, say: "It being undoubtedly true that even when a softer catheter is used, the steady, gentle pressure of the column of fluid will in a few minutes overcome the resistance of the compressor urethræ and sphincter vesicæ muscles and thus allow the lotion to flow backward into the prostatic urethra and the bladder." Also, when we distend the anterior urethra with an injection by a hand syringe and keep it distended (which is the only proper way of using this method), the steady, gentle pressure against the muscle will cause it to yield and allow some of the contents to escape into the posterior urethra. This fact is of supreme importance and cannot be too emphatically emphasized, to wit, that while rough handling and spasmodic jerks will increase the tonus or spasm of the cut-off muscle, gentle but steady pressure, on the other hand, will cause it to yield perhaps only for a second and allow some of the contents of the anterior urethra to get into the posterior urethra. It must, however, not be imagined that when, under these circumstances the cut-off muscle yields that it yields entirely and opens widely and allows the fluid which is under tension to rush full force into the posterior urethra; not at all, it yields, as it were under protest, only slightly at a time and immediately closes, and only a few drops of the fluid in the anterior urethra oozes past under very low pressure into the posterior urethra.

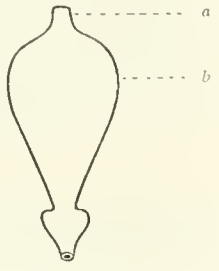

Fig. 4.—Nozzle for irrigating apparatus: A, For insertion into the urethra. B, Bulging portion closing the meatus.

Another fact might with advantage be mentioned here. It is now admitted by all genitourinary authorities that cystitis as a complication of gonorrhea is of comparative rarity, that even when it does occur it is only the small portion adjacent to the posterior urethra, the so-called bladder neck, which in reality might almost be considered as part of the posterior urethra, that becomes affected, and that the gonococcus rarely, if ever, infects the bladder proper even if put into that organ.

We are now in a position to understand the difference in results between irrigations of the anterior urethra by hand syringe or catheter, and intravesical irrigation. Consider for a moment the condition of the anterior urethra in acute anterior gonorrhea. For a variable distance depending upon the length and virulence of the disease, its mucous membrane with its crypts and folds are filled with pus and gonococci. The ordinary act of urination only washes away part of the pus, as it does not distend the urethra and consequently its folds are not ironed out or obliterated, and whatever pus or bacteria are at the bottom between the folds are not touched. This can easily be appreciated by remembering the difference in size and length of the penis (and consequently of the anterior urethra) in normal urination and in erection. In the latter condition, the urethra is physiologically lengthened and all folds obliterated (Fig. 1).

If now we introduce the catheter into the anterior urethra and simply wash out the anterior urethra through it, we do not distend the urethra, as the fluid is allowed to come out of the meatus as fast as it goes in and is never under pressure; besides, that portion of the urethra beyond the eye of the catheter is not affected by the irrigating fluid, and the very putting in of the catheter pushes forward any pus with which it comes in contact. The same is true if we (or the patient) use a hand syringe and gently inject, as is generally advised, any fluid into the anterior urethra. As long as it is not distended so as to resemble a glass tube, its folds will not be obliterated, infection will remain behind, which in due time will find its way into the posterior urethra.

But, it has been argued, that it is possible either with a hand syringe or irrigator, to completely distend the anterior urethra *without* the necessity of allowing the fluid to enter the posterior urethra and bladder. This is undoubtedly true, but let us see what happens. The patient first urinates, which washes away some of the infective material, but not all. A portion of it, at least, as we have seen, is left between the folds of the undistended urethra. The injecting fluid as it comes from the meatus and goes in, distending the urtehra and obliterating its folds, pushes in advance of it some of this material and carries it towards the cut-off muscle. There would be no harm in this, as it would come out at the meatus if the cut-off muscle were an absolutely water-tight cut-off. This, as we have seen, is, however, not the case. Be we ever so gentle, if we distend the anterior urethra and bring pressure to bear on the cut-off muscle, it will now and then relax and allow a drop or two of the fluid nearest to it to escape into the posterior urethra. This is more likely to occur with such solutions where it is necessary, in order to obtain the best gonoccidal action, to keep the fluid in the urethra from between five to ten minutes. As we have seen, the column of fluid under the steady pressure will in this length of time cause an occasional relaxation of the muscle. Let but one drop of pus get beyond it into the posterior urethra and the gonococci therein will be safe, for even if some of the injecting fluid goes with it, it does not go in with sufficient force, nor is it while in there under sufficient tension to do any good.

In other words, in using the hand syringe method we are caught in the following dilemma: Either we do not distend the urethra, in which case we do not reach the gonococci at the bottom of and between

the folds of mucous membrane, or we do distend it, but run the great chance of causing a relaxation of the cut-off muscle and allowing the gonococci to be forced into the posterior urethra.

It might, perhaps, be asked why in every case treated by the hand syringe method the posterior urethra does not become involved. The answer is simple and further illustrates the truth of the above contention. In former years, before the advent of the new silver salts, most every acute anterior gonorrhea did, indeed, become posterior. With the advent of the new silver salts with their marked gonoccidal properties it is possible, if the patient is seen early enough, to kill off very rapidly every gonococcus and then, of course, there is no infection to push backward. The cases must, however, be seen very early, indeed, and the treatment is really more an abortive than a curative one. Hence it is that the statistics of the hand syringe method have improved since the new silver salts have come into use. There is still another reason for this improvement. Almost all of these newer silver salts must be used cold, as warming or heating them is liable to spoil them. Now any cold injection causes a spasm of the constrictor muscle, that is, it contracts more firmly and makes almost, for the time being, a water-tight closure between the anterior and posterior urethra and thus prevents more than a warm solution would a passage of fluid from the anterior to the posterior urethra. Of course, in time the muscle tires and relaxes, but it does not do so as soon as with warmer solutions.

For sake of argument I might even admit that a careful physician, bearing these facts in mind, could possibly distend the anterior urethra without infecting the posterior urethra, although I am even disposed to doubt it, as we have absolutely no control of the reflex of the cut-off muscle and no way of positively preventing its relaxation now and then. But even if a skilled and careful physician could do it, this would be little argument in favor of the hand syringe method of treating gonorrhea. For by this method we understand that the physician merely gives the patient a prescription for a certain injection, instructs him what kind of a syringe he is to get, and how to use it. The physician himself does not see the patient three or four times a day and inject his urethra. This is done by the patient himself, and it can readily be understood, that when it is doubtful whether a skilled physician can do the thing, it can certainly not be done by the patient. It is only necessary that during a single *one* of the many injections the patient has to give himself in the course of a gonorrhea, the cut-off muscle relax and allow a drop of pus to get beyond it, to set up a posterior urethritis; for, as before indicated, once the gonococci get beyond the cut-off muscle they are safe, for the little irrigation fluid that goes in with them does not enter with sufficient force, nor is it under sufficient tension to do any good. Or again, even if the irrigating fluid that enters the posterior urethra with the pus at the moment of relaxation of the cut-off muscle were sufficient to kill off most of the gonococci, it is only necessary for one gonococcus to survive to cause a posterior urethritis, for being beyond the cut-off muscle it is safe from attack, as the injections are only supposed to influence the anterior urethra.

There is yet another feature to which I desire to call attention. The mucous membrane of the anterior urethra contains the openings of the ducts of several glands. These ducts pursue a more or less oblique course directed forward towards the meatus. These glands or follicles and their ducts bear an important relationship to the infection of gonorrhea. They are frequently infected in acute gonorrhea, and, as a result of their anatomical peculiarities, they retain the gonococci even after those on the surface of the urethra have been killed. They are the cause of a large percentage of the chronicity of anterior gonorrhea. When the urethra is not distended they look like Fig. 2, but when distended they appear as in Fig. 3.

Now let us see what happens to these glands and their contents during ordinary hand syringe irrigation. As the urethra becomes distended, the front (meatus) opening being closed by the nozzle of the syringe, the posterior opening being more or less closed by the spasm of the cut-off muscle, it can readily be seen that any pressure of the distending fluid must be exerted directly upon the lateral (also superior and inferior) walls of the urethra and bear directly upon these glands and their ducts. Inasmuch as these ducts open obliquely and not directly vertically on the mucous membrane, in other words, the ducts run more or less parallel to the walls of the urethra in the connective tissue (obliquely) before they open on the mucous membrane, it can readily be understood that this pressure must have the tendency to cause the walls of the ducts to come into contact, in other words, to close them up and thus actually to prevent the emptying of the contents of the glands. It is true that when the nozzle is removed from the meatus and the fluid is let out, there is a tendency to draw or suck out some of the contents of the follicles and ducts, but this suction force cannot be very powerful, as it is limited to the elastic recoil of the walls of the anterior urethra and has not even the muscular power of the bladder to help expel the fluid as in ordinary urination. Thus we see that the ordinary hand syringe injection, except for the slight suction action when the fluid is let out, actually tends to close up the ducts and force the purulent contents deeper into the deep portions of the glands.

Let us now see how all this differs from intravesical irrigation. In order to be clear I shall briefly describe this method of treatment. I shall not go into detail, but refer those who desire to my more extensive article on this subject published in the *New York Medical Journal*, Jan. 30, 1909.

By intravesical irrigation as I practise it, I mean the forcing of fluid from the meatus into the bladder without the intervention of a catheter. The patient first urinates, which washes away a large portion of the pus from the anterior urethra. Then a special nozzle (Fig. 4), which I have described in the paper referred to, is connected with the rubber tubing of a douche bag containing the irrigating fluid and hanging about 4½ feet above the level of the penis. This nozzle is applied to the meatus and the fluid from the bag is allowed to flow into the urethra. The anterior urethra is thoroughly distended and irrigated. Thus far the effect is like anterior irrigation by any other method, except that it is much more thorough. The urethra is much more distended and its folds much more obliterated than can be done by the hand syringe method. I will admit that some of the pus and gonococci may be pushed into the posterior urethra, but, and here is the main point, the irrigation does not stop here.

After several irrigations up to the cut-off muscle this muscle relaxes and the irrigating fluid goes, and continues to go, full force into the bladder, irrigating and distending the posterior urethra, carrying everything before it into the bladder, where, as we have seen, it can do no harm. We thus see that any pus or gonococci that have been temporarily pushed into the posterior urethra while the anterior urethra was being irrigated, are not safe there, because they are pushed forward with the irrigating fluid into the bladder. The irrigating fluid continues to flow into the bladder till that organ is distended (that is, till the patient feels "full"), thus thoroughly churning up the pus with the irrigating fluid, so that every portion of it comes in contact with it and is affected by the gonoccidal action of the fluid. What happens to the pus, etc., in the glands and ducts all along the urethra? The irrigating fluid rushing through the urethra under pressure has the effect of sucking out the contents of these ducts and carrying it with it into the bladder, where it is churned up with the antiseptic irrigation fluid.

White and Martin quote Janet as saying that the chief object of intravesical irrigation with permanganate of potash is that it causes a certain edema of the mucous membrane of the urethra, which so alters the culture ground that no gonococci can live therein. "If the treatment is carried too far the growth of the microbe is encouraged: if not carried far enough inhibition ceases. . . . The special skill in treating this disease depends upon recognizing the required condition of reaction and in so regulating the strength and the frequency of treatment that this condition is maintained for several days."

I have quoted somewhat in full from one of our most recent and best text-books on gonorrhea in order to show their theory of intravesical irrigation. I cannot, however, agree with this theory. It seems to me that this method of treatment would rest upon a very slim foundation, indeed, and would produce most uncertain results if it depended upon obtaining exactly the right amount of edema of the mucous membrane of the urethra, no more and no less. To my mind, as above stated, its success depends upon, in the first place, and thorough ironing out of the entire urethra, in the second place, the thorough mixing up of the pus and irrigation fluid in the bladder, and last but not least, in the suction action as the irrigation fluid goes through the urethra, which mechanically sucks out the purulent contents from the ducts and glands that connect with the urethra and which are a prominent cause of the chronicity of the disease.

When the bladder is distended the nozzle is removed from the meatus and the patient voids the irrigating fluid. Here, again, we have the suction action and even more effectual than before, because the ducts enter the urethra obliquely and point toward the meatus. It is true that there is a certain amount of suction exerted when the fluid is let out in the hand syringe method, but this is far less than in the intravesical method because, as before stated, in the former the action and expelling force is limited merely to the elastic recoil of the urethral walls, while in the latter, besides the suction force that was exerted while the fluid was entering the bladder, we have it again when leaving the bladder and also the powerful muscular action of the bladder to help it.

At my clinic at the Harlem Hospital Dispensary as well as in private practice, every case of gonorrhea is subjected to a modified Kollmann five-glass test (to be described in a subsequent paper), with massage of the prostate. It is surprising how often posterior urethritis is found with these tests when no symptoms of it exist. At the same time when I compare the cases treated at the dispensary where I cannot use the intravesical method (as I am not there every day), also in cases in private practice where patients will not come daily for treatment, with those cases that are treated by the intravesical method, I find posterior urethritis develop much more often in the former classes than in the latter, in which it is, in fact, a rarity.

In conclusion, I would add that this distention method of treating gonorrhea appears to me to be the most natural, and I might almost say physiological (if I may use the term), method. It is simply reversing the thing in the same way it has been acquired. When a man acquires gonorrhea his penis is in the erect position, his urethra is lengthened, its folds are obliterated. Now the gonococcus enters the urethra while in this condition. Immediately after coitus the penis becomes flaccid, the urethra shortened and consequently in folds, and the gonococci are therefore entrapped between the folds of mucous membrane (Fig. 1). What is more natural, therefore, in order to get rid of them again, than to reverse the order, to obliterate the folds and distend the urethra so as to bring it in the same condition as it was when the gonorrhea was acquired?

667 MADISON AVENUE.

Gangrene of Leg Following Diphtheria.—Rolleston reports a case of this condition and draws attention to the fact that though more than eight weeks elapsed between the occurrence of the gangrene and the amputation, no harm resulted from the delay. An earlier operation was considered inadvisable owing to the boy's general enfeeblement and his cardiac condition. For the first fortnight following the onset of the gangrene the temperature ranged between 96° and 100° Fahrenheit, but subsequently it remained practically normal.—*British Journal of Children's Diseases.*

PERFORATING WOUNDS OF UTERUS; WITH A REPORT OF TWENTY CASES.

By EMORY LANPHEAR, M.D., Ph.D., LL.D.,

ST. LOUIS, MO.,

PROFESSOR OF CLINICAL SURGERY IN THE AMERICAN MEDICAL COLLEGE; CONSULTING GYNECOLOGIST TO THE ELLEN OSBORNE HOSPITAL.

Wounds of Uterus. In *Medical Herald*, November, 1910, Dr. Palmer Findley of Omaha records six cases of perforating wounds of the uterus and briefly reviews the literature of the subject. Much to my surprise, his article contains this statement: "Out of a total of 154 reported cases there have been 108 recoveries, with 42 deaths and 4 not recorded." Also: "The expectant plan of treatment has been pursued in 66 reported cases, with 21 fatalities. Abdominal section with the necessary repairs has been done in 72 reported cases with 52 recoveries and 17 deaths and 3 not recorded; vaginal hysterectomy 15 times, with 10 recoveries, 4 deaths, and 1 not recorded." It is astonishing that no greater number of cases has been recorded, for, judging by my own experience, there must have been thousands of such cases. I am sure I have perforated the uterus at least forty times myself during curettement! Indeed, the accident has been so frequent (and regarded as so trivial) that of late years I have failed to index the cases and therefore can only, at present writing, report from memory of surroundings peculiar circumstanecs, etc. The first time a perforation occurred in my own work (*i.e.* to my knowledge) the shock to me was far more severe than to the patient; and the lesson not to open the abdomen unless serious symptoms arise was most forcibly impressed upon my mind. The case was as follows:

Case I.—Abdominal Section for Accidental Perforation. Mrs. —, age 32, patient of Dr. W. H. Manson of Burlington, Kan., was admitted to St. Joseph's Hospital, Kansas City, for curettage. The os having been properly dilated and the scraping nearly done, a sudden push sent the curette through the top of the uterus behind fundus. Hastily the patient was prepared for abdominal section. As soon as possible the fundus was brought up into the wound for arrest of expected alarming hemorrhage. To our astonishment there was only a trace of blood in the pelvis and the point of perforation was not to be found as such! There was an abrasion of the serosa where the curette passed through, but it was fully half an inch distant from the place where the instrument had penetrated the musculosa, downward traction on uterus causing displacement or gliding of peritoneal coat of uterus. A catgut suture (apparently superfluous) was passed around the opening in the peritoneal covering and the abdomen closed. Patient made a good recovery, as she probably would have done if the uterus had been merely cleaned and drained.

Vaginal Hysterectomies for Perforation.—Owing to the small number of recorded cases mentioned by Palmer in which hysterectomy was performed I will first give a few such cases from my records.

Case II.—Perforation of Fundus by Abortionist. Mrs. C., patient of Dr. W. P. Gordon; age 30; operation September 8, 1910, in farmhouse; criminal abortion seven weeks ago at third month, three weeks in bed from retained placenta and sepsis; at time of operation peritonitis from attempt of abortionist to secure placenta with "screw" curette. On opening Douglas's pouch much pus discharged; large hole felt near fundus. Vaginal hysterectomy was performed by lamplight. Specimen showed huge rent on posterior wall, several days old. Pelvis irrigated and loosely packed. Patient had stormy convalescence, but recovered.

Case III.—Vaginal Hysterectomy for Perforation of Uterus. Mrs. C.; age 35; patient of Dr. S. A. Proctor; in bed four weeks following miscarriage of fifth pregnancy; mass around uterus, fever and distended abdomen. Operation April 25, 1908; removal of large uterus and right ovary. On opening uterus placenta of third month found with stinking sinus through uterine wall into suppurative mass around right ovary. Investigation showed that a doctor had "curetted" patient two weeks before her admission to hospital and that "child-bed fever" followed, for relief of which Dr. Proctor was called. Patient promptly recovered.

Case IV.—Vaginal Hysterectomy for Pelvic Infection from Perforation. Mrs. N.; age 30; patient of Dr. S. J. Burch; mother of six children, last four weeks old; had retained placenta for which some doctor curetted. Operation, October 3, 1907: Vaginal hysterectomy and removal of left tube and ovary with abscess in broad ligament. Examination of specimen showed "tube" leading from just above internal os through into abscess of left side of pelvis. Patient had a slow convalescence, but is now in good condition.

Case V.—Vaginal Hysterectomy for Multiple Perforations. Mrs. J.; age 29; confined July 27, 1903; in labor thirteen hours, on tenth day had mastitis and beginning puerperal mania (septic), and since has had temperature 100-103°. Examination showed enlarged, tender uterus, nasty discharge, pelvic exudate. At Centenary Hospital, August 25, with Dr. R. H. Finley; dilated cervix; dilator tore through internal os into peritoneal cavity. On attempting to curette, uterine tissue proved so soft and boggy that instrument perforated in several places; so made vaginal hysterectomy, no pus in pelvis. August 28, patient complained so much of pelvic pain that house doctor removed gauze pack; collapse came soon. Eight hours later omentum and gut were found at vulva! She was chloroformed and intestine returned, after washing, and gauze packed into vagina. She never rallied from the shock.

Case VI.—Porro Operation for Pelvic Abscess from Perforation. Mrs. G.; age 28; patient of Dr. H. G. Nicks, pregnant ten weeks; past four days intense pelvic pain, with formation of mass in broad ligament like ruptured tubal pregnancy of intraligamentous type; temperature 104°. Operation at Missouri Baptist Sanitarium, August 29, 1902, revealed fibrocystic tumor of uterus in folds of broad ligament pushing uterus strongly to left, with pelvic peritonitis and abscess-formation. A Porro operation was performed. Examination of specimen showed several pus pockets, all due to punctures of uterine wall from vagina! Memorandum September 30: "Patient has made an ideal recovery."

Case VII.—Vaginal Hysterectomy for Pelvic Peritonitis Following Perforation. Mrs. B.; age 30; patient of Dr. W. M. Dunn, was admitted to Woman's Hospital July 20, 1901, for sepsis following "jabbing" by midwife for abortion of ninth week pregnancy; fetus expelled July 17, after three days of flooding, but no placenta; temperature 104°, with stinking discharge. July 21, os was dilated (Goodell) and placenta removed with finger. Large hole in left side of uterus, anteriorly, could be made out. On account of precarious condition of patient

nothing more was done except to insert drain. She did not do well; pelvic exudate continuing and temperature remaining high. August 26, with Drs. J. C. Murphy and G. H. Thompson, I made vaginal hysterectomy with removal of both tubes and one ovary. Adhesions were exceedingly dense and omentum glued around injured tissues firmly, but there was no hemorrhage and little shock. She made a perfect and speedy recovery.

Case VIII.—Vaginal Hysterectomy for Perforated Uterus. Mrs. C., patient of Dr. J. Earl Dennis of Kansas City, was confined about 2 P. M. At 4 P. M. the doctor attempted extraction of adherent placenta by introducing hand into uterus and digging fingers behind placenta. He "dug" through uterine wall, got a loop of ileum in the hole, and "dug" a huge rent in the mesentery. On withdrawing his hand full of débris he found this to consist of blood-clot and a large mass of gut! At 6 P. M. I found fully three feet of dead intestine between patient's legs. After hastily removing the uterus by application of clamps the bowel was pulled down and resected and returned to the abdomen, and the pelvis cleaned out and tamponed with gauze. The woman died within a few hours.

Instrumental Perforations. Case IX.—Perforation with curette. Miss T., age 26, operated on March 1, 1900, with Dr. Alfred de Roulet, at St. Mary's Infirmary, for foul-smelling discharge from uterus. During curettage, in spite of extra care on account of fragility of uterine wall, instrument suddenly plunged through anterior wall near fundus. Patient had tempestuous time for about two weeks (emesis being most prominent symptom) but finally made perfect recovery.

Case X.—Perforation of Uterus by Abortionist. B. C., age 17, patient of Dr. G. E. McCosh, was admitted to Woman's Hospital September 21, 1894, with temperature of 106°; had abortion produced four days ago. Much stinking débris curetted away; puncture of uterus discovered by finger. Cul-de-sac of Douglas opened and much blood and pus discharged. As condition was critical nothing further was attempted except irrigation and loose pack in both uterus and pelvis. Death from peritonitis (acute sepsis, temperature running 105° to 106°) on September 24.

Case XI.—Perforation During Curettage. Mrs. K., age 27, patient of Dr. Geo. E. McCosh, was subjected to curettement July 12, 1902. Dilatation was easy but uterus unusually soft and boggy (menstrual flow lasting eight to twelve days). Near conclusion of curettement instrument passed through posterior wall of uterus just above internal os; so plugged uterine canal with iodoform gauze and vagina rather tightly with 1 to 2000 bichloride gauze. She recovered promptly without any pelvic symptoms or unusual degree of pain.

Case XII.—Perforation into Tubal Abscess. Mrs. B., of Cairo, Ill., admitted to St. Mary's Infirmary December 27, 1902, with gonorrheal endometritis and left tubal abscess. January 5, 1902, with Dr. R. H. Finley dilated cervix and began curetting; suddenly entered abscess of tube (or in broad ligament) with deluge of pus. Inserted dilator and stretched opening and then drained abscess through cervix. She made a slow recovery and while not entirely well has never consented to radical operation though now seriously considering it.

Case XIII.—Perforation During Dilatation of Cervix. Mrs. M., aged 30, patient of Dr. G. E. McCosh, was admitted to Woman's Hospital, November 30, 1902, with temperature of 105° from sapremia following abortion. While dilating internal os with the Leonard dilator sudden rupture occurred, and on passing a Volkmann spoon presumably into cavity of uterus its end could be felt distinctly through the thin abdominal wall to left of umbilicus, and on withdrawal omentum followed; this was crowded back and the hole tamponed. Then putrid fetal remains were scooped out, the uterus wiped dry, and a gauze drain inserted. December 8 her temperature was normal and she was permitted to return to East St. Louis.

Case XIV.—Perforation During Curettage. Mrs. C., age 29, patient of Dr. Paul Cook, admitted to Woman's Hospital October 22, 1902; she had pelvic peritonitis in spring following abortion during gonorrhea, now suffering from gonorrheal endometritis; advised cleaning out pelvis, but patient insisted upon curettage. October 23, with Drs. R. H. Finley and Paul Cook, dilated cervix and curetted, perforating anterior uterine wall. Hole was packed tightly with iodoform gauze and uterus lightly with same. She was discharged from hospital November 3.

Case XV.—Perforation During Removal of Sloughing Fibroid. M. H. of Iowa, age 29, was delivered at Woman's Hospital October 5, 1902, of first child. After some hours of ineffectual labor she was taken to operating room and the os was found filled with fibroid tumor. This was pushed above brim of pelvis, forceps applied to head and forcible delivery accomplished, tumor being held back by fingers until head engaged. December 1, 1902, with Drs. R. H. Finley and J. C. Hallam, curetted away this fibroid, now necrotic; curette perforated uterus; made vaginal section for drainage, as sloughing fibroid was infected with saprophytes. Patient made an uneventful recovery, and is still in good health, though possessing two other intramural fibromata.

Case XVI.—Perforation During Curettage. Mrs. M., age 38, two children, five miscarriages, last one year ago with sepsis; subinvolution. Operation April 7, 1904, with Dr. D. C. Todd. Uterus 6 inches deep, soft, much granular matter; in curetting, instrument perforated uterine wall anterior to fundus and could be felt plainly near umbilicus. Uterus sponged dry and loosely packed. Cervix repaired with seven sutures. No symptom was noted from perforation. Patient still in excellent health.

Case XVII.—Perforation of Horn in Uterus Bicornis. Mrs. G., patient of Drs. W. H. & E. B. Mayfield, had a nasty, stinking discharge from cervix for two weeks, with sapremia developing. Operation November 21, 1906. On dilating external os two cervical canals were found and each was dilated, as both were discharging fetid material and decaying blood. Further examination now disclosed uterus bicornis with dead fetus in each horn. Left cervical canal dilated easily and dead fetus and placenta removed. Right canal firmer and placenta adherent; in detaching placenta curette passed through into peritoneal cavity. Both cornua were hastily wiped out and lightly tamponed. Patient made an uneventful recovery.

Case XVIII.—Perforation of Uterus During Curettage. Miss K., age 26, patient of Dr. C. B. Foreman, operated on October 20, 1908. In curetting soft, deep uterus, curette suddenly perforated fundus. As abdomen was to be opened for other work, curette was left with 4 inches projecting into

belly to locate opening on account of difficulty of finding location in previous cases. Hole was closed by pursestring suture through serosa (and uterus later drained with wick), old adhesions broken up, round ligaments shortened for retroversion, and abdomen closed. Through lumbar incision a wandering kidney was decapsulated and fixed. Patient made a happy recovery.

Case XIX.—Perforation of Uterus with Curette. Mrs. B., age 32, patient of Dr. Julia E. Blaich, temperature 103° after chill following abortion, decaying placenta. May 16, 1910, under chloroform, dilated os and removed stinking mass of placenta of three months' development and some clots; in mopping out with gauze around forceps, hole found in right side of uterus behind uterine arteries, but as no exudate or blood clot could be detected no opening was made in cul-de-sac. Uterus and walls of perforation were touched with tincture of iodine, light pack put in, and patient had speedy recovery.

Case XX.—Perforation Found at Curettage. Mrs. M., age 36, patient of Dr. C. Bernstorff, operation November 3, 1910. In September, at the third month of gestation, patient pushed penholder into uterus; miscarried; stinking discharge past three days, with temperature 102° and abdominal distention. On dilatation of os, hole in anterior wall of uterus found, plugged by omentum, firmly adherent. Curetted out placental débris, mopped uterine cavity with tincture of iodine, liberated omentum, and amputated part acting as plug, pushed epiploon back, and tamponed opening with gauze. Gauze removed on fifth day and patient left hospital on eleventh day apparently well.

My records of work in Kansas City when surgeon to the German Hospital, All Saints' Hospital, and one year at St. Joseph's Hospital have been scattered so I cannot refer to them; but they contained numbers of cases similar to the ones here reported. In one case a crochet needle was found near the spleen, in another a hairpin in the bladder, and in a third a penholder in the broad ligament—all self-introduced and all penetrating the uterine walls—one prong of the hairpin having traversed the peritoneum. A case indelibly impressed upon my memory (on account of the effort made to send the "perforator" to the penitentiary, where he later landed) was this:

Case XXI.—Abdominal Section for Perforation with Peritonitis. Kate E., age 17, was admitted to All Saints' Hospital (Kansas City), February 22, 1892, as patient of Dr. J. Earl Dennis, suffering from sepsis from retention of fragments of placenta following instrumental abortion. February 23, dilatation of os for removal of decaying material revealed rent in uterus, with pelvic peritonitis marked; but on account of non-consent of parents radical operation was not performed. February 25, general peritonitis was well developed and parents' consent finally given for operation. Abdominal section revealed large hole in wall of uterus, pelvis filled with pus, and general peritonitis. Specimen and body given coroner February 26, 1892.

While only twenty-one cases are here mentioned, I am sure that careful examination of my records would show fully as many more. As in no case of my own, all accidental and done in hospital, have symptoms of any consequence followed except where gonorrheal infection was known to exist, it is my opinion that perforation of the uterine wall during curettage is not a serious matter, and I believe it to be a very frequent accident. But perforation of the uterus for production of abortion is quite another matter, as is shown by contrast of the abortion cases with the accident cases in this series. Yet, even in the cases due to the abortionist's clumsy work, the surgeon should not be in haste to do radical work unless symptoms are urgent. In this class of work (pelvic peritonitis following criminal or accidental abortion) it is my practice to first clean out and drain the uterus, and, second, to open and drain the cul-de-sac of Douglas. I have thus treated a large number of patients with a very low mortality, even taking in patients who were practically moribund at time of operation. There is, usually, plenty of time to do the ablation work after it is evident that mere drainage (plus the exaggerated Fowler position, now) will not save life.

THE A—B—C OF ETHER ADMINISTRATION.

By PALUEL J. FLAGG, M.D.,

YONKERS, N. Y.

As early as 1805 inhalations of ether were recommended by Warren of Boston to relieve pulmonary distress in advanced phthisis. In 1812 ether intoxication by inhalation was said to have been frequently practised in Philadelphia, but it was not until October 17, 1846, that Warren at the instance of W. G. Morton of Boston used ether as a surgical anesthetic at the Massachusetts General Hospital. A few days subsequently C. T. Jackson of Boston claimed to have used ether as a dental anesthetic. The important facts to be borne in mind, therefore, are W. T. Morton and the year 1846.

Ether is commonly prepared as follows: ethyl-alcohol reacts with sulphuric acid to form ethyl-sulphuric-acid and water. In the presence of an excess of alcohol ether is formed, and sulphuric acid is reformed as a residue. This is known as the continuous etherification process.

The quality of the ether used is occasionally open to question. This because of age and exposure of the particular specimen or possibly because of its faulty manufacture. There are five simple tests to be made before using a specimen of ether of questionable quality: 1. acetic acid, 2. water and alcohol, 3. residue, 4. odor, 5. aldehyde. (1) There should not be an undue amount of exposure to air. When ether is kept for some time it becomes changed to a mixture containing acetic acid. Ether should not affect blue litmus paper even after twenty-four hours' contact. (2) There should not be an undue amount of water or alcohol present. Ether for anesthesia should contain 96 parts ether and 4 parts alcohol, as against 74 parts ether and 16 parts alcohol found in ordinary ether. If 20 cc. of ether and 20 cc. of water previously saturated with ether be shaken together the ether layer on separation should not measure less than 19.5 cc. (3) Upon evaporation ether should leave no residue. (4) Allowed to evaporate spontaneously there should be no perceptible foreign odor present when the last traces of ether have disappeared. (5) There should be no change of color on the addition of KOH. This indicates the presence of an aldehyde.

Ether is given internally as a stimulant and carminative in doses of from 1 to 2 drams. It is best given in capsules or iced water. Two or three minutes before its administration a small

piece of ice may be placed in the spoon, the patient at the same time being directed to suck a small piece of ice in order to lower the temperature of his mouth. This procedure prevents the volatilization of the ether on coming in contact with the otherwise warm mucous membranes. Hoffman's anodyne, a combination of ether, alcohol, and a heavy oil, is a favorite method of administration. Ether plays its most important part as an anesthetic. Ether vapor is 2.5 times as heavy as air and for this reason it may be given in comparatively concentrated form from a source of saturation located some inches above the face.

The object of the anesthetist should be, first, the patient's safety and comfort; secondly, his own ease. It frequently happens that, after having given a number of ethers, the anesthetist, instead of developing a technique conducive to the comfort of the patient, develops instead a method whereby he can save time and make the administration easier for himself. The personality of the patient is lost through the commonplaceness of the work. The anesthetist forgets that, while this affair may be very ordinary to himself, yet it is the culmination of long hours of anxiety on the part of the patient. He does not realize how far a few words of personal interest and sympathy on his part will go toward placing the patient in an easy receptive frame of mind. It is not fair to limit our kindness to private patients, ward cases are in need of sympathy as well.

It is well to prepare the patient as thoroughly as possible for the operation. He should be fasting, having taken nothing but a small amount of fluid, if the length of the fast demand it. A patient with diabetes runs a great risk in taking ether as he may never recover consciousness. The routine heart, lung, and urine examination is important because of the danger following the use of ether as well as the danger of immediate complications during its administration. One must not forget false teeth. These cases will occasionally slip through the hands of the best nurses. It is important to have at hand atropine, strychnine, ammonia, ergot, and oxygen in case of cardiac failure. It is thought that much of the irritation of the upper respiratory tract may be avoided by moistening the mask with 10 per cent. menthol in alcohol. A drop or two of sterile olive oil will prevent the formation of corneal ulcers, an accident which may follow ether dropping into the eye during deep anesthesia. Ether should be brought no nearer than five feet to any light. This applies to the *x*-ray and thermocautery as well as to open fireplaces and low gas lights.

The relative merits of the closed cone and the drop method, as observed by the writer, are as follows: Anesthesia may be begun in practically every case by the drop method. When the period of unconsciousness is reached it may be either continued or the closed cone may be resorted to as occasion demands. Many cases, especially women, do well with a continuous drop method. The exceptions respond to the use of the closed cone. This is used until deep anesthesia has been produced, the drop method then taking its place. This combined method may be used where the drop method alone would be a complete failure. The advantage of the drop method in the early stage lies in the lessened irritation of the pharyngeal mucosa through the thorough dilution with air and in the lessened sense of suffocation experienced by the patient. If the patient be directed to count out loud, anesthesia will come on more speedily because of the increased respiratory efforts demanded. The entire anesthesia, as far as the patient is concerned, lies within the bounds of consciousness. If unconsciousness can be pleasantly induced, the entire anesthesia, from the patient's standpoint, is a complete success. By the use of the drop method the reflexes are kept under a finer control. This form of administration, by demanding closer attention, is rendered less monotonous. The size of the inhaler is of considerable importance. It is essential that ether before being inhaled be thoroughly mixed with air. For this reason the screen should not lie close to the face. The use of a towel for a mask is objectionable for this reason. There is less irritation when using the large mask, one which allows of an air space of from one and a half to two inches in height. Children respond well to the drop method from the start. One can usually produce any required depth of anesthesia in young children by this method.

If ether is pushed from the beginning, especially with the closed cone, there is usually much more spasm and consequent cyanosis than there would be, had the initial stage proceeded easily. Ether acts upon the nervous system by inhibiting, first, the intellectual centers; second, the sensory portion of the spinal cord; third, the motor tracts; fourth, the sensory portion of the medulla, and, fifth, the motor portion of the medulla. When the motor portion of the medulla becomes involved the respiration fails. Anesthesia develops when ether is present in the blood serum in the proportion of 1-400. A patient should be out of ether to the point of vomiting when the operation is concluded. Laparotomies require such a depth of anesthesia that the sensory impressions to the medulla are benumbed, otherwise the shock of handling the viscera is thought to be worse than the additional amount of ether used. Many hold that tonsillectomies and adenoidectomies should be done under deep anesthesia, because while faucial irritation is still present there is great danger of cardiac failure through reflex vagus stimulation. Perineorraphies and other minor operations may be done to advantage under a less degree of anesthesia.

In giving ether the most important signs to watch are the following: 1, respiration; 2, corneal reflex; 3, pupil; 4, color; 5, pulse; 6, Mayo's sign; 7, diaphragmatic integrity. The character of the respiration appears to be greatly influenced by the mental condition of the patient. If quiet and composed all goes well, but if the patient be very nervous the respiration is liable to be irregular throughout. Hence the value of suggestion at the onset. When the ether is given gradually there is little or no laryngeal spasm. The stoppage of the respiration at this period is said to be due to reflex irritation of the trifacial and pneumogastric nerves. Following this arrest of the respiration, but little ether should be given, as the inspiration which follows is usually very deep. Coughing may occur and is best relieved by raising the head, holding the jaw forward, and temporarily stopping the ether. The character of the respiration in the second stage differs according to the temperament. This stage is usually ushered in by deepened stertorous respiration. It frequently occurs, however, that the respiration

simply becomes more rapid and remains perfectly quiet. An entire operation may be carried on with the patient breathing as quietly as though asleep. This condition is more liable to occur with women and with patients who are very sick. A heavily-built, full-blooded old man was brought in suffering from intestinal obstruction. An operation for reduction was performed with the patient breathing perfectly quiet, but with all the other signs of deep anesthesia. The respirations during deep anesthesia will be found to remain between 30 and 45 a minute. They may, however, go up to 60 a minute in a nervous person. If these respirations occur regularly and the other signs do not show deep anesthesia there is no cause for alarm. Increasing depth of anesthesia shows itself in marked stertor, shallowness, rapidity, irregularity, and finally stoppage. Stoppage of the respiration in the presence of marked cyanosis may relieve itself spontaneously, since it is due to asphyxia secondary to obstruction to the respiration. It is practically always relieved by bringing the jaw forward by pressure on the angles or tension exerted on the cheek. It is often necessary to pull the tongue forward in order to free the breathing passages. Stoppage of the respiration in the presence of pallor is very dangerous, as it indicates an involvement of the higher centers. Hiccough sometimes occurs during anesthesia, is a manifestation of laryngeal spasm, and usually disappears spontaneously when the anesthesia is deepened. Sometimes during deep anesthesia the patient may develop a crowing respiration simulating increased respiratory efforts when coming out of ether. If the other signs show deep anesthesia the patient should not be pushed. Mucus occasionally collects in the throat, especially if the first stage has been very excitable. It is difficult to relieve the throat of this obstruction. A wick of gauze put into the corner of the mouth is of some value. The Trendelenberg position is the most favorable, as the mucus thereby drains out of the throat. As anesthesia deepens this condition becomes less objectionable because of the diminished irritation occasioned by its presence. Vomiting is frequently the result of swallowing too frequently during the early stages. The ingested ether stimulates the stomach to evacuate its contents. During the operation all unnecessary pressure on the patient's body should be avoided. Surplus blankets and the weight of the operator leaning on the chest should be done away with as much as possible.

The corneal upper eyelid reflex: Both eyes should be tested, as one is frequently more active than the other. The most active may be taken as the standard. This sign, if properly elicited, does not appear to cause after-annoyance to the patient. It is the most reliable sign of the exact degree of anesthesia present at any given time. To quote from Gardner the technique is as follows: "Standing above or behind the patient the pulp or palmar surface of the middle finger only of one hand should be gently inserted between the closed eyelids and made to draw the upper lid open as far as to disclose two-thirds of the cornea. While doing this the finger pulp very gently but definitely brushes against the surface of the cornea, passing first over its exact center, and then against the palpebral edge of the upper eyelid, in one movement, which ends with the sudden letting go of the lid from the finger. The degree of activity with which the upper eyelid then closes constitutes the most invariable evidence of the extent to which the muscular and nervous systems are at that moment paralyzed by the anesthetic."

The pupillary signs: Before starting it is well to look at the size of the pupils. Sometimes they are irregular, sometimes unusually dilated, as shortly after the use of mydriatics. Sometimes one of them is a glass eye. The usual behavior of the pupil is as follows: During the initial stage it is widely dilated. As anesthesia progresses and muscular relaxation comes on, it becomes contracted to smaller than normal. If the anesthesia is then pushed it again widely dilates. The probable explanation of this phenomenon is as follows: The pupil has two sets of muscles, the dilator and the sphincter pupilæ. The dilator muscles are supplied by the long ciliary nerves which communicate with the cervical sympathetic ganglia. The sphincter muscles are supplied by the short ciliary nerves, which originate from the third cranial nerve, which is, of course, of central origin. During the first stage of excitement the sympathetic nerves are everywhere stimulated, the cervical sympathetic included. The dilator muscles in the eye are consequently stimulated and the pupil dilates. As the sympathetic system is associated with the sensory portion of the cord it is the earliest to go to sleep. The dilator nerves become paralyzed and the action of the deeper centers through the third nerve, by way of the short ciliary nerves, becomes apparent in pupillary contraction. This condition of contraction is also present in normal sleep. It is thought that this contraction is in part due to the dilatation of the ciliary blood-vessels. As the anesthesia is carried further the higher centers become affected and the action of the third nerve in contracting the pupil becomes gradually less. The pupil then dilates by virtue of the ciliary muscles. These allow the lens to bulge forward and enlarge the pupillary lumen. This action is supposedly aided by the elastic fibers in the pupil and the emptying of the pupillary blood-vessels. Dilatation of the pupil accompanies awakening and vomiting. As the patient comes out of ether the pupil again contracts. Nystagmus or oscillations of the eyeball frequently occur in the early stages but disappear as anesthesia deepens. The reaction to light disappears when full anesthesia has been reached.

Mayo's sign: The so-called Mayo's sign consists of a relaxation of the muscles controlling the lower jaw. Early in anesthesia the jaw is rigid; later on it can easily be moved up and down, anteriorly and posteriorly, by pressure at the angles.

The pulse: The pulse is an indication of the operative condition of the patient, loss of blood, shock, etc., rather than the ether status. It is not a very good indicator, as it gives its warning too late. If the pulse is weak, intermittent pressure over the heart may aid it in carrying on the circulation. It has been proposed to pass one hand up under the ribs, holding the other externally, then to press the heart between the two hands. "Sudden arrest of the heart is the most dangerous accident of anesthesia and, as Embly has shown, it is due to inhibitory stimulation acting on the weakened heart. The treatment

consists in inversion and artificial respiration. Atropine should be injected in order to paralyze the inhibitory mechanism, and in view of the arrest of the circulation it might be thrown directly into the heart by means of a long hypodermic needle." (Cushny.) The color is usually dependent upon the condition of the respiration and the heart. It is valuable as a guarantee that the respiration and the heart are both doing nicely. Cyanosis is, of course, an urgent sign. Pinching the ear and the skin will sometimes show the condition of the circulation to advantage. It is remarkable in how short a time a badly cyanosed patient will clear up when the obstruction to his respiration has been removed. In a case of this kind the clearing up of the cyanosis is the all-important sign. A good color at the end of the operation is an indication of the general good condition of the patient.

Diaphragmatic integrity: The integrity of the diaphragm is closely associated with the respiratory condition. It is valuable in the later stages of asphyxia. The early action of ether is to stimulate the contraction of the diaphragm. So great are these contractions that if the glottis be closed the diaphragm on contracting forces the abdominal contents downward and forward. As anesthesia becomes deeper and deeper these excursions are smaller and smaller, but, as in the case of a normal respiration during inspiration, the abdominal contents are still forced down and out. If anesthesia is now pushed the excursions decrease in size and finally cease. The action of inspiration may then aspirate the diaphragm and the abdominal contents into the chest cavity. This sinking in of the abdomen during inspiration is an important sign of danger, as it indicates paralysis of the diaphragm. When the diaphragm ceases to act anesthesia has been carried to its legitimate limit and further anesthesia should be carried on with the greatest of care. Paralysis of the respiratory center is first evident in paralysis of the diaphragm. The neck muscles then come into play. These cease, the jaw drops, and respiration stops. The treatment of cessation of the respiration when pallor is present is practically limited to artificial respiration with oxygen. Strychnine and ergot are supposed to be of some value as also rhythmical traction of the tongue fourteen to sixteen times a minute. One may also try sprinkling ether on the abdomen and chest. Nearly all cases of sudden death are due to grave kidney and cardiac lesions. The mortality is estimated variously as from 1-20,000 to 1-16,000.

123 South Broadway.

IMPRESSIONS AS TO THE VALUE OF SALVARSAN (EHRLICH-HATA 606).*

By WILLIAM B. TRIMBLE, M.D.,

NEW YORK,

LECTURER ON DISEASES OF THE SKIN, NEW YORK UNIVERSITY (UNIVERSITY AND BELLEVUE); CHIEF OF THE COLLEGE CLINIC; ASSISTANT AT THE NEW YORK SKIN AND CANCER HOSPITAL.

It is generally understood that comparisons are odious, but it becomes necessary, in order to arrive at the true therapeutic value of the new drug, to study and compare its effects with the older method of treatment. The very fact that we are experimenting with any drug, the object of which is to cure syphilis, is putting it to the severest of trials; since to be just and fair, it must be tested alongside that celebrated and time-honored remedy, mercury, which has carried approval for years, and was supposed to be the only specific in medicine.

We have already a drug that will remove the lesions in a manner truly magical; one that will cause the disappearance of the spirochetes, and also change the Wassermann reaction from positive to negative; it would seem that this trinity of effects would be all that is desirable, but unfortunately we cannot say absolutely that it permanently cures syphilis.

In the opinion of the author it does cure syphilis in many instances. The well-known and clearly defined sequelæ, that follow in the wake of lues, need no comment here, but they are in the minority as compared to the number of people infected with the disease. Reasons are legion why a great number are not cured, but this is a digression.

The new Ehrlich preparation will also bring about the same result that mercury will effect in removing the lesions, the spirochetes, and the positive serum reaction; whether it will permanently eradicate the disease, time alone will tell, so this part of the subject may be summarily dismissed. It might be added just here, that in the light of my observations and the writings of others, it seems most unlikely that one dose, or even three or four doses, will accomplish this result. However, it is useless to speculate along these lines at the present.

The mission of this article is to speak comparatively, and also to record some observations made while working with the new remedy in the wards of the New York Skin and Cancer Hospital in connection with my colleague, Howard Fox.

The Rapidity of Disappearance of the Lesions.—It has been found from personal experience with a fair sized group of cases that the new remedy does cause the mucous membrane lesions to vanish faster than can be effected with the old drug. It has also been found that it causes the eroded chancres to heal over somewhat faster than other methods of treatment; but the induration, so frequently met with around initial lesions, is not absorbed with any greater rapidity.

It has also been observed that the action of salvarsan on the papular cutaneous syphilides is somewhat slower than that produced by mercury. Its effect on the cutaneous tertiary manifestation has also been carefully watched, and the clinical results have been about the same as those produced by mercury, in reference to length of time of resolution.

The Action on the Spirochetes.—Salvarsan undoubtedly has a magical effect in causing the disappearance of the *Spirochæta palida;* in some cases they can not be found forty-eight hours after injection; such rapid action is hardly possible with mercury, though it must be remembered that it is no easy matter to find the treponema after three or four days of vigorous mercurial treatment.

The Effect on the Complement Fixation Reaction.—There are some statements in the literature in regard to the blood reaction changing from positive to negative within 10, 14, and 18 days; this does not coincide with our work at the hospital, as the best case in the series remained positive for 33 days. In other cases it became negative in 46, 54, 70, and 85 days.

*Work done in the New York Skin and Cancer Hospital service of Dr. Geo. H. Fox. Over 70 cases have been treated up to this writing.

It will also be noticed in the chart that some of the cases have remained positive up to the time of writing. As is the case with mercury, the reaction will, in certain instances, become negative, and after a variable time again become positive, sometimes coincident with the relapse and at other times when no clinical manifestations are visible. Even though the superiority of salvarsan might be granted as to its quick effect on the Wassermann test, I am inclined to the belief that, if the patients were treated vigorously with mercury, for instance by the injection method, the time of disappearance of the positive blood reaction would almost equal that of salvarsan. This question, however, is as yet unsettled.

The most important question now arises: Will arsenobenzol (606) permanently cure syphilis? In the light of the experience gained from personal work at the hospital, and also from the observation of other cases, it is thought that it will not; but the question can best be answered by asking another: Will any drug cure syphilis when, after its administration, numerous and frequent relapses take place? In the group of cases treated, which comprised the primary, secondary, and tertiary forms of the disease, relapses occurred in a ratio of about 25 per cent. In some of the patients, after a period of two of three months, the clinical manifestations have not entirely disappeared and the Wassermann test still remains positive; under such conditions a recurrence could hardly be expected, as the original disease is still present, though somewhat improved.

In other cases salvarsan has acted marvelously; and paradoxical as it may seem, relapse has occurred in several of the most brilliant results. Another point has been noticed in reference to the recurrences, viz., the rapidity with which relapse takes place is almost equal to that of the quick disappearance of the original lesions. In some cases the lesions, with the accompanying spirochetes, reappeared in three weeks. For example: In one case of a young woman with a large indurated chancre of the lip, numerous mucous patches and a mild roseola on the trunk, complement fixation + +, five decigrams in emulsion were given according to the method of Wechselmann; the chancre, which was eroded, healed over very quickly; the induration was absorbed somewhat slowly, and the macular eruption faded in due time. A large indurated swelling appeared at the site of injection, which was tender, but not very painful, after the first 24 hours; the spirochetes vanished in 48 hours, having been present in large numbers before treatment. The patient was dismissed from the hospital, and in exactly three weeks from the time of injection, she reappeared with extensive mucous patches in the mouth, a distinct miliary papular syphilide covering the body, and the *Spirochæta pallida* was again demonstrated.

Another case of a young man with a pustulo crustaceous syphilide of a rather malignant type, with large lesions on the legs and forearms, and a severe ulcerating lesion on the nose—Wassermann, + +. When this patient was admitted, he avowed he had never been able to tolerate mercury, although his physical appearance somewhat denied this. Five decigrams of salvarsan in neutral suspension were administered to him, and the drug had a wonderful effect, the lesions absolutely healing in about one month. He returned in three weeks with a recurrence of the lesions in practically the same locations as before. After observation for one week, he was again injected, this time in the muscles, with the drug in solution, according to the method of Lesser. After this distinct improvement was noticed, but the resolution was slower than after the first dose. The improvement continued up to a certain point, when the ulceration again became active, and the second relapse was apparent. After an interval of five weeks, this patient was given a third dose of five decigrams intravenously, followed by improvement, but not so rapidly as before.

Still another case in which nearly the whole hard and soft palate was covered with a luetic ulceration might be referred to. A small perforation of the palate was apparent when he first presented himself for treatment; five decigrams were given in clear solution intramuscularly, and in three days the ulceration had imprpoved at least 50 per cent., and in one week was practically healed. Two weeks later the lesions reappeared quite as intense as originally. A second dose of .45 gram was administered to this patient in the same manner as previously, and in the same location; the ulceration again almost healed, when in three weeks he again relapsed. In the meantime two other perforations in the roof of his mouth had appeared. The pain was marked after the first injection, but very slight following the second.

It can be readily seen from the cases cited above how quickly the relapse occurred. This recalls the fact that, if a luetic is relieved of his symptoms by a short course of mercurial treatment, the patient will, as a rule, remain free for a number of months, and sometimes a year or more. On the other hand, the drug produced in several of the patients a very brilliant result.

One case, a woman with a large crusted serpigenous syphilide on the side of the face and head, was much benefited in one week, and the lesion disappeared entirely in four weeks. Up to the present time no relapse has occurred, and the result is considered excellent.

Another case may be cited of a young man with large mucous patches on both tonsils, a luetic infiltration of the vocal cords, and slight ulceration at the base of right arytenoid. He could not raise his voice above a whisper, and swallowing was difficult. The mucous patches were healed in three days, and at the end of a week his voice was normal.

The last two patients referred to were treated with intramuscular injections of the clear solution.

Several other cases in the series, mostly of the tertiary variety, healed slowly and have remained without recurrence up to this time. The pain following the injection has varied greatly in the different individuals. Generally speaking, it was intense for about eight hours, following the neutral suspension, and very severe for twelve hours in most of the cases treated with the clear solution injected into the muscles. The pain from the latter method persisted for several days, but gradually diminished.

The induration at the site of injection also varied in intensity in different patients. The swelling and induration were marked following the administration of the Wechselmann method, and persisted for weeks; in a few patients it is still present. The indurations from the intramuscular method were larger and more intense than those following the neutral suspension, but subsided much earlier.

In three patients injected in the buttocks, the induration and swelling was very mild, and the pain caused very little discomfort; in one other the pain and hardness was intense on one side, but scarcely

noticeable on the other. It is thought that the vigorous massage applied to the last four cases immediately after treatment, and kept up for several days, was very instrumental in minimizing the irritating effect of the drug. The systemic reaction generally occurred on the second day; the temperature changes averaging 100° to 101.5°. The pulse rate was accelerated in nearly every case, ranging from 85 to 100.

No attempt will be made here to describe the different ways of preparation of the drug. Suffice it to say that in this group of cases it has been used *intravenously* in clear solution, both by the Schreiber and the gravitation method; *intramuscularly* in solution according to Lesser; and *subcutaneously* in suspension, after the manner of Wechselmann. It has also been given suspended in oil, iodipin oil, and also in a new oil, with which I am now experimenting. This latter method consists merely in rubbing up the salvarsan to 3 or 4 c.c. of the oil and injecting it deep into the muscles of the buttocks.

The rapidity of effect of the drug is in direct ratio to the order of administration as given above.

It is too early at this time to make any definite statements regarding the best method of administration; if it were not for the pain, it appears the soluble intramuscular injections would be preferable; it carries with it no danger; it is almost as quick in its effects as the intravenous method, and perhaps is not so rapidly eliminated, which, in a way, is an advantage. This point was brought sharply to mind by a recent case. The patient, a robust young man, had a chancre, clinically typical, on the corona glandis. It had existed 11 days, was indurated, but no secondary manifestations had appeared. Although the diagnosis seemed absolute, it was not forgotten that mistakes in diagnosis are sometimes made in dealing with venereal sores, so the spirocheta was sought and found in large numbers. Blood for the Wassermann test was taken, and a negative reaction anticipated; but the result was positive. If the patient had presented himself earlier and the Wassermann had been negative, it would have shown that antibodies had not as yet been formed. The spirochetes walled off, as it were. If one desired to inject him under these conditions, trying to reach Ehrlich's goal of sterilisans magna, and the intravenous method employed, it would be possible for the remedy to be eliminated before the spirochetes were released from the chancre; afterwards the spirochetes might seep through the chancre wall, and the patient have his secondaries as usual. If the drug was administered by intramuscular injection, it would remain in the system longer, and we would have a better chance of having it there when the invasion from the chancre took place.

Like many other things in medical literature, there is some divergence of opinion regarding the merits of the new remedy. Some observers, Wechselmann, Herxheimer, Neisser, Junkerman, Jeanselme, Fordyce, and many others, give glowing accounts; whereas Fischer, Bohac, Sobotka, Hoffman, Brocq, Weintrud, Gottheil, and others, are very conservative, and make some adverse reports.

The results from this work conform very closely to those of Gaucher. This last named author, in a paper before the French Academy of Medicine, gave a most valuable, lucid, and conservative exposition of the subject. No bad effects have been encountered, but in several of the cases the pigmentation following the resolution of the lesions has been rather pronounced and persistent; the idea has suggested itself that perhaps the arsenic had a tendency to fix this pigmentation temporarily, as arsenic is known to cause such a condition in some instances.

There was a transient albuminuria in one or two of the patients.

In conclusion, after this experience with the drug, it can be said:

1. Salvarsan causes an unusual and very rapid disappearance of the mucous membrane lesions.
2. Its action is no faster than mercury, if as fast, in the papular form of the disease.
3. It does not act more quickly than mercury on the cutaneous tertiary manifestations of syphilis.
4. Relapses occur in many of the cases.
5. These relapses come very quickly after apparent cure.
6. The tonic effect is excellent, many of the patients improving wonderfully in general condition.
7. It is a very potent remedy, which will probably find a fixed place in the therapeutics of syphilis for use in special cases, but will not supersede mercury.

AN UNUSUAL CASE OF PLACENTA PREVIA.

By JACOB OHLBAUM, M.D.,

NEW YORK.

Mrs. O., aged twenty-four; married three years; nativity, United States. Does not remember having the usual illnesses of childhood. Had one natural miscarriage about a year after marriage of about two months' duration, and had a curettage performed for retained secundines. No complications developed after curettage was performed and the woman menstruated normally every twenty-eight days until September 25, 1909. After this period menstruation ceased and the patient began to have all the early signs of pregnancy; vomiting was very distressing up till about the third month, then it ceased and thereafter the patient felt very comfortable.

At about four and one-half months of pregnancy the patient commenced to feel life and was comfortable and well up to the seventh month, when she phoned for the writer and complained of losing a lot of blood, but having no pain. Questioning the patient did not reveal that she had done any hard labor which might have caused her to have a hemorrhage. Vaginal examination revealed several large clots in the vagina and the os completely closed. Patient was put under morphine and kept in bed for a week, during which time all hemorrhage had ceased, and absolutely no discharge or stain appeared. For three weeks after patient was allowed to get up and about she felt very comfortable and complained of no pain or hemorrhage until one evening she had another hemorrhage, much more severe than the first, which took place a month previously. Vaginal examination showed clots in the vagina; os was open, permitting the finger to enter the uterus, and the diagnosis of placenta previa made.

Dr. Cragin was consulted the next day, June 4, and he advised immediate delivery. The patient was prepared and put under a mild anesthetic. The cervix and the vagina were completely packed with plain sterilized gauze. In about twelve hours after the insertion of the tamponnade the patient had such severe pains that it was decided to remove the gauze and see what dilatation was present. During the re-

moval of the gauze patient had quite a hemorrhage, but there was sufficient dilatation to permit of bipolar version and doing immediate extraction. Fortunately the child was not large and the breech was not left in the canal, but immediately delivered. There was no difficulty experienced in delivering the placenta and a dram of an ergot preparation used hypodermically worked like magic in contracting the uterus. There was comparatively little shock to speak about. Twenty-four hours after delivery patient complained of pain in the lower right quadrant, abdomen somewhat tense and painful on pressure; slight rise in temperature and pulse; no tympanites or chill. Ice bags were applied to affected area which apparently gave patient a great deal of comfort. Lochia was profuse, but no odor detected.

June 9. A slight distinct mass was palpable over McBurney's point. Patient had a severe chill, lasting about twenty minutes, during which period she remained with limbs flexed, pulse intermittent; delirious and vomiting mucus and eructations of gas; temperature rising to 106.8° per rectum. Ice bag and alcohol sponges continuously and quinia phenacitin and salol given internally.

June 10, 1910, 9 A. M. Temperature normal; pulse 80; respiration 18; feels comfortable and is hungry. Mass on right side appears the same and very painful on pressure. June 10, 4 P. M. Patient had a severe chill and temperature rose to 107°. June 11. Temperature at 11 A. M. normal; patient feels comfortable and hungry. Ice bag still continued and hot saline douches are given three times a day. June 12, A. M. Temperature 101°; feels comfortable all day and at 8 P. M. temperature is 103°.

June 13, 3 A. M. Patient had a severe chill, lasting fifty minutes; at 4 A. M. temperature was 108°, and at 8 A. M. temperature, pulse, and respiration dropped to normal.

Dr. Pinkham was called into consultation at this period and advised waiting about a laparotomy, as the mass and inflammation might resolve itself. The question of diagnosis was either between appendicitis or salpingitis.

June 14, 8 A. M. Temperature 97°, a drop of 11° within a period of twenty-four hours. For the next eight days, from June 18 to June 22, temperature varied between 100° and 103° A. M. and P. M., respectively.

On June 22 operation was decided upon, the patient having been nourished and strengthened to a sufficient degree to attempt operation. The mass could be felt with difficulty in the vagina by forcing one's finger into the cul-de-sac. To try and drain this mass through the vagina was not deemed expedient and a small incision was made over McBurney's point and the pus given free vent and drainage. A large rubber tube inserted into the wound kept the pus draining nicely. The diagnosis of suppurative appendicitis was made.

Patient made an uneventful recovery. Three months after operation the patient complained of a burning sensation upon micturition and of a yellow discharge from the vagina. Smears made from both the urethra and the cervical canal show the presence of gonococci. Patient denies having had intercourse since the operation. Husband was questioned and admitted having an old gleet, which every now and then gave him a little trouble. The probabilities are that this case was a ruptured pyosalpinx, patient in all likelihood having been infected and had a latent gonorrheal salpingitis and the accouchement perforce reignited this inflammation which caused the formation of this large pus sac.

At this writing the patient is free from the urethritis and has again started to menstruate, menstruation having ceased for five months after accouchement.

1665 Lexington Avenue.

Latent Pyloric Stenosis.—R. Dahl describes four cases of this condition which passed from a state of compensation to one of broken compensation. This transition was characterized by attacks of severe vomiting, hyperacidity, epigastric pains, which attacks were relieved for a shorter or longer time by a brief fasting cure.—*Mittheilungen aus der Grenzgebieten des Medizin und Chirurgie.*

Congenital Atresia of Bile Ducts.—Weber and Dorner state that the gradual deepening of the jaundice in caes of congenital obliteration of bile ducts, the enlargement of the liver as well as of the spleen, and (above all) the definite clinical evidence that the jaundice is obstructive, distinguish these cases from cases of congenital acholuric (so-called "hemolytic") jaundice with splenomegaly.—*British Journal of Children's Diseases.*

Cocainism Mistaken for Alcoholism.—Higier says these two conditions are often confounded. A subject, perhaps a dentist, of neuropathic tendencies begins to use cocaine in small doses, increased day by day. He begins to suffer with tremor and insomnia. His troubles usually begin when he voluntarily cuts down the dose. He suffers from collapse, bad dreams, mental confusion, and hallucinations bearing on the conviction of immediate death. He develops a high state of mania. The attending physicians diagnosticate alcoholism and treat the patient accordingly. There is indeed a strong resemblance between the two mental states. Morphine is of value in either case. The cocaine psychosis is an acute hallucinatory insanity, with a greater tendency to suicide than is shown by the alcoholic. The author insists that cocainomania is easily curable and but seldom relapses. Withdrawal does not occasion the severe abstinence phenomena present in alcohol and morphine addicts.—*Münchener medizinische Wochenschrift.*

The Skin Reaction with Tuberculin in Syphilitic and Metasyphilitic Affections.—G. Mingazzini gives the results of the test with tuberculin in syphilis. There has been an attempt to obtain a reaction with syphilin similar to the test with tuberculin in tuberculosis. But the results of this reaction have not been satisfactory. Therefore a test was made in syphilitic cases with tuberculin itself. It has been found that in marked cases of syphilis a positive reaction is obtained with tuberculin in the skin test. Out of 49 syphilitics in whom clinically there was no evidence of tuberculosis a positive skin reaction was obtained in 44. Of these patients 5 had initial manifestations of syphilis, 22 secondary lesions, 6 tertiary symptoms, and 12 metasyphilitic lesions. In two cases the reaction was weak, in one inactive. The reaction was less marked than in tuberculosis. In 37 cases in which the history excluded tuberculosis the skin reaction was made. In two of these autopsy showed no tuberculous foci in the body. The skin reaction was positive in 12 cases. The stage of the disease does not affect the reaction. But the general condition seems to influence it, the reaction being less positive in cachectic cases. Mercurial or iodide treatment has no effect on the reaction. The skin reaction and the serodiagnosis have parallel results. The skin reaction will not suffice to make a differential diagnosis between tuberculosis and syphilis. In cases in which we suspect a syphilitic or metasyphilitic disease and in which we can exclude tuberculosis clinically, the positive entire action is in favor of a luetic infection.—*Il Policlinico.*

THE PRESENT-DAY CONCEPTION OF HEART FAILURE.

A SUBJECT in which laboratory investigation and hospital experience have been accorded an undue prominence over the everyday observations of the general practitioner is that of the interpretation of the proximate causes of heart failure. In the first of the Oliver-Sharpey Lectures on this subject delivered before the Royal College of Physicians of London, and published in the *Lancet* and *British Medical Journal*, April 8, 1911, James Mackenzie emphasizes the fact that the position of the general practitioner in the rank of investigators has not been appreciated and his attempts have been too frequently received with a chilling indifference, while the usual exponents of medical science are not brought into intimate contact with the varying manifestations of disease. Particularly in the study of diseases of the heart, the general practitioner has the opportunity of observing the subtle changes that go on as the disease advances.

The views of Mackenzie upon this subject arrest the attention, because they are those of a clinician whose brilliant work in the study of heart disease enables him to speak with authority. He notes that the popular conception of heart failure is erroneous. In accentuating the importance of limited lesions, the appreciation of the heart's action as a whole has been lost sight of, with the result that the real significance of symptoms has never been fully appreciated, while the study of heart affections from the viewpoint of isolated disease has actually led to a misinterpretation of the meaning of many of the most obvious phenomena. The real nature of heart failure not being understood, and experience showing that death occurs unexpectedly, signs or symptoms which are considered abnormal, and whose nature is not known, are viewed with suspicion or as portents of evil. Murmurs are not necessarily evidences of an impaired heart. The assumption has been made without sufficient evidence that all valve murmurs are signs of defects. For example, the tricuspid valves are normally barely competent; a slight degree of physiological dilatation will render them incompetent. The auricles are specially constructed to meet this incompetence. Wilkinson King has shown that this tricuspid incompetence, with the reservoir function of the auricles and great veins, and even of the liver, is a special provision in diving animals, and he described the modified condition in man as the "safety valve function" of the tricuspid valve. Mitral regurgitation due to damaged valves can go on for fifty years without crippling the heart in its work, which shows that even organic valvular incompetence is not incompatible with good health and longevity.

Mackenzie emphasizes the fact that irregularities of the heart are not necessarily a sign of impairment. Any cause that irritates or excites the heart muscle, as fever, excitement, or effort, at once abolishes the irregularity. So marked are these causes in abolishing the irregularity that Mackenzie has for some years looked upon the presence of the irregularity as a possible evidence of the integrity of the heart muscle, and so far from considering it an evidence of disease or of infirmity, it may, within certain limits, be considered a positive evidence of a healthy heart. Although back-pressure may modify the symptoms, it is never the essential cause of the heart failure. The essential cause of the latter is due to changes in the heart muscle. About 70 per cent. of the cases of severe heart failure met with in general practice, with dyspnea and dropsy, owe their onset to auricular fibrillation.

The study of fibrillation of the heart muscle is one to which considerable attention has been paid within recent years. This condition is a state in which the individual fibers or small bundles of fibers contract rapidly and apparently independently of each other, so that the chambers cease to contract as a whole, but stand still, while all their fibers are in incessant movement. The result of these fibrillary contractions is at once to suspend the contractile function of the chambers affected, as shown by Bishop in a paper published in this issue. When the ventricles pass into such a state death ensues, but when the auricles pass into fibrillation death does not occur immediately, for the fibrillation cannot pass along the bundle which connects the auricles with the ventricles. What does occur is that the stimuli for contraction are rapidly and irregularly thrown upon the bundle by the fibrillating auricle; and if the bundle is able to transmit the stimuli, and the ventricles able to receive them, the ventricles are stimulated in a rapid and irregular manner. Mackenzie notes that the back-pressure theory has failed to recognize that the changes which have led directly to the production of heart failure and produced such symptoms as dyspnea, dropsy, enlargement of the liver, are due to the sudden inception of a different rhythm in the heart's contraction by fibrillation of the auricle.

ACTIVE IMMUNIZATION AGAINST DIPHTHERIA.

THE introduction of antitoxin has been followed by a very marked reduction of mortality in diphtheria, yet the disease in its more virulent forms is still an extremely dangerous affection. It is not to be wondered at, therefore, that prevention of this infection should continue to be as important an aim of the physician as the treatment of an infection once developed. Diphtheria antitoxin gives a certain passive immunity to persons exposed or in danger of

exposure to the infection. Yet its administration is not without possible unpleasant features, such as the various manifestations of "serum disease," from a simple rash to a systemic disturbance threatening the life of the patient. Moreover, the passive immunity obtained is not perfect nor is it very prolonged.

These various considerations have prompted several Russian physicians to experiment with the production of active immunity to the disease, and in *Russkii Vrach,* No. 5, 1911, N. P. Blumenau tells of these experiments and of the application of the knowledge obtained through them. S. K. Dsershovsky was the first to produce an active immunity in his own organism by introducing subcutaneously rising doses of the diphtheria toxin; he finally succeeded in producing such a degree of immunity that one cubic centimeter of his blood contained one normal antitoxin unit. Boldireff followed his example and showed that very minute doses of the toxin were sufficient to produce a fair degree of active immunity. Finally Dsershovsky again showed on himself that the toxin may be introduced in the simplest way possible, namely, by passing into the nostrils for several days in succession pledgets of cotton soaked in the toxin.

Blumenau applied this method of immunization in the cases of seventeen children and, after some minor modifications of the technique, succeeded in producing a high degree of active immunity in most of the cases. He also shows that the immunity thus produced is of much longer duration than the passive immunity resulting from the injection of antitoxin. As children suffering from scarlet fever or from measles in the hospital under his supervision have seemed to be especially apt to develop an infection with the diphtheria bacilli, Blumenau expects to apply the method of producing active immunity in all such patients under his supervision. Immunization with the antitoxin in the usual manner was tried by Blumenau, but did not prevent quite frequent infection with diphtheria. The degree of immunity in such cases is certainly much less than that produced by the use of the active toxin of the disease. The older method must remain, however, for use in patients already exposed to infection, for the immunity follows immediately upon the introduction of the antitoxin, while active immunity takes a certain space of time for its development.

AMERICAN MADE FLOUR AND APPENDICITIS.

In the *Medical Chronicle*, for March just passed, Edred M. Corner of London devotes many pages to a consideration of the life history, function, and inflammation of the appendix. Corner deals fully with the physiology of digestion and points out that there is no possibility of doubt that the appendix in the human being is a vestigial structure, a survival of a larger cecum in some possibly herbivorous ancestor. Nature, however, being a good handmaiden, has taken upon herself to endow a dying structure with a secondary function, which is to be found in the large amount of lymphoid tissue aggregated in the ileocecal region and particularly in the appendix. The use of the lymphoid tissue is to supply at short notice leucocytes as watchmen to guard the body and to protect it against invasion by the organisms which are present in the interior of the cecum. Therefore, as the appendix contains the largest amount of lymphoid tissue it is the chief point of vantage of the watchmen, and according to Corner this is indeed the function with which nature has endowed it.

Now as to the influence of American manufactured flour on the causation of appendicitis. It is well understood that the alimentary canal contains more things than food and bacteria. The great storehouse of worms in the alimentary canal is the ileocecal region. Any abnormal articles that we swallow, such as pins, pips, filings, hairs from our brushes, and so forth, are expected to be found in the ileocecal region, seeing that the cecum is the place where the foodstuff undergoes a pause or rest. The statement that certain foreign bodies swallowed are very apt to reach the appendix must be accepted ere the force of Corner's argument as to the injurious effects upon that organ of American made flour can be properly appreciated. Appendicitis first became a popular disease in America and among the wealthier classes. Further, the first epidemic, if such a term be applicable, of appendicitis in America was to a great extent contemporaneous with the preparation of flour for bread in the mills by means of big steel rollers of a fluted type. Now these rollers quickly wear down and have to be frequently replaced. What then, asks Corner, becomes of the material which has come off the roller worn out in the process. Obviously it must be in the flour of our bread. That is to say a considerable proportion of the flour thus made contains minute pieces of steel which, when consumed, stay sufficiently long in the appendix to create irritation and in some instances to set up appendicitis.

At first this process of preparing flour was expensive and the flour was bought and eaten only by wealthy Americans among whom appendicitis became prevalent. Curiously, the increase of appendicitis in England almost synchronizes with the introduction of the American methods of preparing flour into that country. More proof of the effects of this milled flour in the production of appendicitis seems to be afforded by the fact that, as bread made from it became cheaper, *pari passu* appendicitis became more frequent and more generally recognized among the less rich of America. Lastly, the class of men who held out the longest against appendicitis were the colored people. They ate bread prepared by their own methods until milled flour became so cheap that it was simpler for the negros to buy bread made from it than to prepare their own, the result being that appendicitis has become increasingly frequent among them. The charge laid against American milled flour is plausibly argued, but hardly impresses one with its probability. Indeed it is probable that in a single hour's ride on a railroad on a dusty summer day one swallows more iron and other mineral particles than could be found in a year's supply of bread from American made flour.

The Finger-Nails as Evidences of Recent Severe Illness.

In the *British Medical Journal*, April 15, is a paper by Norman Flower dealing with the condition of the finger-nails during and after severe illness. Flower brings forward several cases which have come under his observation in support of the contention that finger-nails undergo a change during and after serious illness. The most interesting part of the paper is, however, the testimony of Sir Samuel Wilke to the same effect. Wilke was the first to notice the white markings on the nails as being indicative of death or approaching death. He says: "In all the cases I have seen or known where these marks have appeared the patient has been at death's door; he has been regarded by the medical man and friends as dangerously ill, and, indeed, in the jaws of death, unless he soon rallied and then recovered. He has always become cold, pulseless, with death written on his face, causing the greatest anxiety to his friends, and in this state he may continue for some hours or several days. If he should fortunately recover the sign of death is written upon him." Wilkie mentions several cases in proof of this argument, and one case in particular is deserving of quotation. "Then," he says, "came a case which I considered proof of my opinion of what these marks indicate, as they occurred in a gentleman who had had no illness, but was twice nearly dead from sea sickness on his voyage to America and also on his return. He was sent to me by a friend, and he brought with him a photograph of his hand with the marking on the nails. These were two white lines or curves with a good space between. I then reckoned the time of his starting, the time he was in America, and the time of his return by the line which was nearest to the root of the nail and the uppermost of the lines. The dates were all accurate, the history of the voyage was written upon him." Whether these finger-nail markings are of any value in prognosis is doubtful. In the first place it may be presumed that they do not always occur and then those who have them do not always die. They are apparently simple curiosities.

Lymphadenoma from a Surgical Point of View.

This affection is generally known in England as Hodgkin's disease, although there is more than one claim prior to that of the late demonstrator of morbid anatomy at Guy's Hospital to the honor of having first described the condition. The disease is considered from a surgical standpoint by Sir Frederick Eve in the *Practitioner*, April, 1911. Eve's advice with regard to operating for this condition is like Punch's advice to those thinking of getting married, "Don't." His experience is that when lymphadenomatous glands have been removed the disease rapidly recurs, and especially in those cases of a chronic character. With respect of other methods of treatment Eve stated that he has tried Coley's fluid, but without success. He thinks the assumption that lymphadenoma is of parasitic origin is made with good reason. As to the diagnosis of the disease, the writer says: "It may be broadly stated that the chief distinguishing point between lymphadenomatous and tuberculous enlargement is the great mobility of the glands in the former. If some of the glands are attached to each other or to surrounding structures, and especially if softening can be detected, the disease is probably tubercle." However, in certain stages of lymphadenoma the disease can be distinguished only by excision of a gland and microscopical examination. The sole difficulty in diagnosis arises in the differentiation from tuberculous enlargement. Secondary malignant and syphilitic disease can be readily excluded. It is somewhat encouraging to the physician to find that there are yet some surgeons who are not convinced of the necessity for operation in every getatable disease or abnormal condition.

Enzymes in the Urine.

The problem of the significance of digestive ferments in the urine is an old one. That such enzymes may be found in the urine is admitted, but to explain their presence therein seems to involve violation of physiological laws. Thus physiology teaches that trypsin cannot reach the urine, because of the normal antitryptic quality of the blood, which may be regarded as indispensable for the preservation of the organism from the action of proteolytic enzymes, since these exert so marked an action on local structures. Grober at a recent session of the Medical Society of Essen-Ruhr (*Berliner klinische Wochenschrift*, No. 10) attempts to sum up our knowledge of this subject, although he deliberately omits consideration of any but proteolytic enzymes. The principal authorities cited are Wittich, Grützner, Neumeister, and Matthes. It appears that the enzymes in the zymogen stage may be absorbed into the blood and eliminated by the kidneys. Pepsin reaches the urine regularly, trypsin exceptionally. When the excretory duct of the pancreas is occluded trypsin begins to appear in the urine; also in diabetes and during the absorption of exudates and infiltrates. Pepsin, if normally present, disappears from the urine in severe disease of the stomach. The writer added that his method—the old fibrin-adhesion test—was not equal to solving the problem of the identity or nonidentity of pepsin and chymosin.

News of the Week.

Hospital Saturday and Sunday.—The distributing committee of the Hospital Saturday and Sunday Association announces that about $112,000 was raised in its recent campaign. In addition to designated gifts already forwarded to the hospitals, amounting to $9,847, the committee appropriated $94,000, making a total of $103,847 sent out this year to date. The apportionment of funds is made on the basis of the amount of certified free service given by each hospital to in-patients without regard to dispensary work.

Tuberculosis Day.—Sunday, April 30, having been designated as "Tuberculosis Day," it was hoped that at church services generally throughout the country special attention would be given to the subject of the prevention of tuberculosis in order to stimulate the interest of the people in the fight against the disease as a moral duty. In endorsing the movement, Governor Dix of New York wrote: "I hope the time will come soon when there will be a county hospital for tuberculosis in every county and a tuberculosis dispensary and visiting nurse in every city and village of considerable size in this State."

Forty Thousand Dollars for Surgical Research.—At a meeting of the trustees of Columbia University, held on May 1, it was announced that a friend of science, who did not wish his name to be known, had given $10,000 a year for four years to further surgical research in the university.

Plague Investigation.—The delegates to the international plague conference in Manchuria have completed their investigations and are now on their way home. It is stated that resolutions were adopted by the conference to the effect that it was unnecessary to interrupt railway travel in case of a plague epidemic since modern science was able to control the disease without difficulty, provided the proper authority was given to the health officers. Other than this, it is said, no practical results were arrived at by the delegates.

Appointments at Columbia University.—Dr. Warfield T. Longcope, formerly of the University of Pennsylvania, has been appointed assistant professor of medicine, and Dr. Henry Pike of the University of Chicago has been made assistant professor of physiology at Columbia University of this city.

Measles Among Soldiers.—Reports of an epidemic of measles of virulent type among the United States soldiers stationed at Nogales, Ariz., have been received.

Automobile Smoke Nuisance.—The New York City Department of Health announces the result of its efforts to abate the nuisance of smoking automobiles in the city. From the end of September, 1910, to the end of April, 1911, 1,819 arrests were made. Fines amounting to $4,856 were imposed in a total of 1,655 of these cases. Sentence was suspended in 84 cases, 75 were discharged, and 4 were held for Special Sessions.

Plague in India.—During the month of February there were about 43,508 deaths from bubonic plague in India, while during March the total of 95,884 was reached.

Down with Mosquitos.—The Montclair, N. J., Health Department has begun a crusade against the mosquito by locating and draining the stagnant pools of water where the insect finds breeding places. A penalty of ten dollars has been fixed for maintaining a pool of water in which mosquito larvæ breed, but it is impossible to prosecute an owner for maintaining such a pool unless mosquito larvæ are actually found.

Jewish Maternity Hospital.—At the fourth annual meeting of the Jewish Maternity Hospital of New York, held recently, the sum of $30,000 was raised by popular subscription. It will be used to erect a new building for which plans are now being prepared.

The Union Hospital.—Several novel features are included in the plans of the new Union Hospital, which has leased the building formerly used by the Fordham Hospital in the Bronx, New York. Instruction in hygiene will be given to the general public and to mothers and housewives, and a special department of office hygiene will undertake to direct business and professional men as to the sanitary conditions under which they should work, and the length of time they should work each day and each year in order to make the most of their time, abilities, and strength. The president of the association is Dr. John F. Holmes.

The Rockaway Beach Hospital and Dispensary, containing 45 beds, will be opened to the public May 8. Dedication exercises were held on April 30. The medical staff is as follows: Attendings, Drs. F. P. Hatfield and A. Goldberg, Surgeons; G. K. W. Schenck and E. L. Friedman, Physicians; Consultants, Drs. H. Fisher, M. S. Kakels, and H. Roth, Surgeons; McCorkle, Leon Louria, and Schwerdtfeger, Physicians; McEvitt, Wm. Linder, A. Rongy, and Ralph Waldo, Gynecologists; Le Grand Kerr, Pediatrist; O. P. Humpstone, Obstetrician; Homer Gibney, Orthopedic Surgeon; Wm. Gottheil, Dermatologist; George Vandergrift, Ophthalmologist; L. A. McClelland, Otologist. The building which was erected by popular subscription, at a cost of $100,000, is four stories high, with a frontage of eighty feet and a depth of forty.

Gift to Preventorium.—The Tuberculosis Preventorium for Children at Farmingdale, N. J., has recently received an anonymous gift of $50,000, which will be used toward the new building fund. It is planned to increase the capacity of the institution to 158 beds.

Marriages in New York.—During the first four months of this year the Marriage License Bureau of New York issued licenses for 11,348 marriages, an increase of 815 over last year, and of 1,630 over 1909.

Bequests.—By the will of the late Dr. Charles A. Oliver of Philadelphia his library on ophthalmology is bequeathed to Harvard University, to constitute the Charles A. Oliver Memorial Ophthalmic Library. Other books are bequeathed to the University Club of Philadelphia. Paintings, pictures, and engravings are bequeathed to Lafayette College. The estate, valued at about $15,000, is to be divided into three equal parts, one of which is to be given to the city of Philadelphia in trust for Wills Eye Hospital, for the purpose of establishing an operating room to be known as the Charles A. Oliver Memorial Operating Room; one-third to the Department of Medicine of the University of Pennsylvania, to establish a fund the income from which is to be used for the purchase of a medal for the student of the graduating class in the Department of Medicine receiving the highest average and passing the best examination in ophthalmology, and one-third to the College of Physicians of Philadelphia, for the establishment of a fund the income from which is to be used in the purchase of journals dealing with ophthalmology.

Bellevue Nurses Graduate.—Twenty-seven women and nineteen men were graduated from the Bellevue Hospital Training School for Nurses, New York, on April 26. The exercises marked the discontinuance of the training school for men nurses.

Dr. John H. W. Rhien has been elected professor of diseases of the nervous system in the Philadelphia Polyclinic and College for Graduates in Medicine in succession to Dr. Wiliam G. Spiller, resigned.

American Climatological Association.—The scientific sessions of the twenty-eighth annual meeting of the association will be held at Montreal, Canada, on June 13 and 14, 1911. Following the annual dinner at the Windsor Hotel, on June 13, the president, Dr. John Winters Brannan of New York, will address the members. Arrangements have been made for entertaining such members as desire to spend June 12, the day before the meeting at Montreal, at Saranac Lake. The secretary of the association is Dr. Guy Hinsdale, Hot Springs, Va.

American Therapeutic Society.—The twelfth annual meeting will be held in the auditorium of

Building B of the Harvard Medical School, Boston, on May 11, 12, and 13, 1911, under the presidency of Dr. Harvey M. Wiley of Washington. Dr. Noble P. Barnes, 208 Maryland avenue, N. E., Washington, is the secretary of the society.

Dr. M. M. Carrick, Assistant Superintendent of the Texas State Epileptic Colony, Abilene, has been appointed by the Governor Superintendent of the Leper's Hospital at a salary of $3,000 per annum, including residence, etc.

The Doctors' Automobile Association will hold its annual meeting at Hotel Astor some time during May, date to be announced later. An address will be given, by Charles J. Glidden of Boston, on "Speed Regulations in Foreign Countries"; Dr. David E. Hoag will discuss "The Interpretation of the Callan Law as Applied to Doctors' Vehicles."

South Carolina Medical Association.—At the sixty-third annual meeting in Charleston on April 18 officers for the ensuing year were elected as follows: *President,* Dr. J. W. Jervey, Greenville; *Vice-Presidents,* Dr. A. E. Baker, Charleston; Dr. J. H. Miller, Cross Hill; Dr. B. H. B. Lee, Summerville; *Secretary,* Dr. E. A. Hines, Seneca; *Treasurer,* Dr. C. P. Aimar, Charleston.

Iowa State Medical Society.—The sixtieth annual session of the society will be held in Des Moines on May 17, 18, and 19, 1911. The address on surgery will be delivered by Dr. George W. Crile of Cleveland, Ohio, and the address on medicine by Dr. J. B. Herrick of Chicago. The president of the association is Dr. M. N. Voldeng of Cherokee.

Eastern Illinois Homeopathic Society.—The following officers were elected at a meeting of the society held in Mattoon on April 15: *President,* Dr. J. J. Rose, Marshall; *Secretary,* Dr. M. H. Whitlock, Charleston; *Treasurer,* Dr. S. H. Mozier, Arcola.

Obituary Notes.—Dr. Herbert M. Nash of Norfolk, Va., a graduate of the University of Virginia Medical Department in 1852; a member of the American Medical Association and the Virginia State and Norfolk County Medical Societies, and for many years quarantine officer of the Port of Norfolk, died at his home on April 26, aged 79 years.

Dr. A. H. Caveness of High Falls, N. C., a graduate of the Baltimore University School of Medicine in 1901, a member of the North Carolina State and Moore County Medical Societies, and coroner of Moore County, died at his home of blood poisoning on April 10.

Dr. Joshua A. Whitman of Beaufort, S. C., a graduate of the Chicago Homeopathic Medical College, in 1886, and a member of the South Carolina State and Beaufort County Medical Societies, died at his home on April 12, aged 81 years.

Dr. John D. Carnahan of Ogden, Utah, a graduate of the Medical Department of the University of Virginia, Charlottesville, in 1872, died at his home on April 7, aged 67 years.

Dr. Archibald M. McKay of Summerville, N. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1858, and a member of the North Carolina State and Harnett County Medical Societies, died at his home on April 15, aged 73 years.

Dr. Gustav Fuchs of St. Louis, Mo., a graduate of the Missouri Medical College, St. Louis, in 1875, a member of the St. Louis Medical Society, and a veteran of the Civil War, died at his home, on April 19, aged 75 years.

Dr. Manning Simons of Charleston, S. C., died at his home in that city on April 18. He was graduated from the Medical College of the State of South Carolina, Charleston, in the class of 1868. He was a member of the American Medical Association, the South Carolina and Charleston County Medical Societies, the Tri-State Medical Association, the American Association of Physicians, and the Chatham Medical Society. At the time of his death, Dr. Simons was professor of abdominal surgery and gynecology in the Medical College of the State of South Carolina, and surgeon to the Roper Hospital and the St. Francis Xavier Infirmary, Charleston. He was 65 years of age.

Dr. John A. Steele of Minneapolis, Minn., a graduate of the Boston University School of Medicine in 1856, died at his home on April 14, aged 74 years.

Dr. Lewis H. Kirk died at Oxford, Pa., on April 26 at the age of 60 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1877. He was a member of the Chester County Medical Society, of the Medical Society of the State of Pennsylvania, and of the American Medical Association.

Dr. John B. Shober died at Philadelphia on April 27, at the age of 52 years, following an operation for cholelithiasis. He was graduated from the medical department of the University of Pennsylvania in the class of 1885. He served a term as resident physician in the Pennsylvania Hospital. He was surgeon to the Gynecean Hospital and gynecologist to Howard Hospital.

Obituary.

HERMAN KNAPP, M.D.

NEW YORK.

Dr. Herman Knapp, for many years one of the foremost ophthalmologists of this city, died at his country home in Mamaroneck, on May 1, at the age of eighty years. He was born in Dauborn, Prussia, on March 17, 1822, and was educated at the universities of Munich, Würzburg, Berlin, Leipzig, Zurich, Vienna, and Giessen, receiving his medical degree from the last-named university in 1854. He studied ophthalmology for four years in the clinics of Paris, London, Utrecht, Berlin, and Heidelberg, and in 1864 became professor of ophthalmology in the University of Heidelberg. While at Heidelberg he founded a hospital and dispensary for eye diseases which later was incorporated into the university.

In 1868 Dr. Knapp came to New York and began the practice of ophthalmology, which he followed with unusual success up to the time of his retirement a few years ago. In 1869 he established the *Archives of Ophthalmology and Otology,* published in English and German, and the same year he founded the New York Ophthalmic and Aural Institute. In 1882 he became professor of ophthalmology in the New York University Medical College, and in 1888, on the death of Dr. Agnew, he was appointed to the same chair in the College of Physicians and Surgeons. This chair he held until 1902, when he was made professor emeritus. Dr. Knapp contributed many articles on diseases of the eye and ear to periodical literature, but wrote only one complete treatise, a work on "Intraocular Tumors." He is survived by two daughters and a son, Dr. Arnold Knapp of this city.

Correspondence.

DUTIES OF THE NAVAL SURGEON.

To the Editor of the Medical Record:

Sir: While it is commonly supposed that the nature of the medical practice on a sea-going vessel is very restricted and that the doctor on a man-of-war is designed to be ornamental socially rather than useful professionally, the facts disprove this. Among the cases treated on this ship in a year are to be mentioned, rare congenital cysts, various unusual skin diseases, affections of eye, ear, nose and throat, nervous diseases, cases of typhoid, pneumonia, appendicitis, diseases of heart and lungs, of kidneys and liver, of the blood, and the various accidental injuries to be expected on such a big floating machine shop as a modern battleship.

If it were desired to compare in amount the strictly medical work on this vessel with that of a civilian practitioner, in an ordinary American town, we should say that the latter would have need of a large and well-equipped office with a thousand dollars worth of instruments and appliances, his telephone would be kept ringing a good part of the day, he would need to have access to a surgical hospital and require the services of a stout horse and buggy or an automobile. His programme would include two hours of work in the city or town dispensary every day, not omitting Sundays and holidays, and about twenty bedside visits per day, exclusive of his surgical patients. Every Sunday morning at the hour when his family was about starting for Sunday school, he would have a dozen or more patients calling at his office for special treatment administered by himself. Once a week he would have an additional clinic for from fifteen to forty patients of a special class, and he would have occasion to operate about once a week on a case, of trivial character, perhaps, but needing ether anesthesia.

During the course of a year this imaginary civilian doctor would have to make about two hundred life insurance examinations. He would have to be present at some fifty odd board meetings during the year. Further, he would have at his command no laboratory, but be under the necessity of doing for himself all the chemical and microscopic investigation necessary to diagnosis. He would have to keep stocked a small drug store and regulate the business thereof. Finally he would have to devote considerably more than an hour every evening to keeping an accurate record, in duplicate, and making an index of every prescription written, of the details of his cases, of every examination made or board attended and of all the laboratory work he performed.

Further, he would have to be the sanitary officer for a prison with, from seven hundred to a thousand odd inmates, making weekly inspections of the building and frequent inspections of the food supplies required for their consumption.

We must suppose, too, that he gave weekly lessons to a class of six or seven ambitious, intelligent and more or less studious young men, and that during the year he gave about fifty lectures on hygiene to a class of twenty or more of his fellow citizens.

The civilian, in conclusion, should be entirely dependent on his own resources and unable to call in, for critical cases, the services of a specialist in any line whatever.

While it is true that our battleships with complements of seven hundred to a thousand men usually carry two doctors, it is to be remembered that the military duties of a naval surgeon demand a certain amount of time—"collision drill," "general quarters," "fire and accident parties," "parades," "landing parties,"—are all participated in by the doctor and take him away, often at the most inopportune moment from his preferred line of work.

J. S. Taylor, M.D.,
Surgeon, U. S. Navy.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

HEART FAILURE.—ASSOCIATION OF CHOREA, RHEUMATISM, AND TUBERCULOSIS.—TEMPERANCE AND SUCCESS.—DIRT IN FOOD.—SATURDAY HOSPITAL FUND.—OBITUARY.

London, April 14, 1911.

Heart failure was the subject chosen for his Oliver-Sharpey lectures at the Royal College of Physicians by Dr. James Mackenzie. His treatment of the subject is of special interest to general practitioners, for they have the opportunity of observing the progress of patients said to be affected by cardiac ailments, and the lecturer himself was able to say he had watched nearly one thousand for a number of years. Thus these lectures differed widely from the usual run of college lectures which deal so frequently with laboratory or hospital observations. The need for the experience of the general practitioner was well set forth by the lecturer, as it is he who comes into contact with the varying manifestations of disease, the trivial ailments which denote the beginning of more serious occurrences, the subtle changes continually going on, the links between various stages, and other circumstances.

The lecturer pointed out the dearth of definite information in most text books on present-day views of his subject—a deficiency due to these books being so often the product of hospital experience only. Murmurs and irregularities are accordingly carefully studied, and the attention is too closely fixed on the mechanical results of valvular incompetency. Now murmurs were not practically recognized until Laennec's time, and then they were regarded as signs of disease, their cause not having been understood, no one having observed them long enough to judge what happened, and this decision, adopted before the facts were appreciated, has prevailed since. The lecturer had long been dissatisfied with the conception of murmurs based on the idea of back pressure, and was prepared for the modern discovery of auricular fibrillation. This presents the subject in a new light, and affords grounds for sound prognosis and rational therapy. This condition may be accompanied by changes in the arteries, and sometimes in the muscle walls of the ventricles, to which last probably the degrees of failure are due, for even when there is fibrillation the impairment of the heart's efficiency may be trifling, though in other cases there will be persistent enfeeblement. If the ventricles pass into a state of fibrillation death ensues, and it has been suggested that this is often the cause of sudden death.

The heart varies its activity with the body's requirements. So Dr. Mackenzie divides the work of its muscle into two parts—one to maintain the circulation during repose. This is the minimal force consistent with life and he calls it the "rest force"; impairment of it is fatal. The other part is called upon during effort and named the "work force." Disturbances of the circulation should be studied

from the standpoint of possible obstacles to the work of the muscles—not as specific affections. Heart failure always begins by exhaustion of the "work force"—slight at first, but if the cause persist it will proceed until the "rest force" is encroached upon and then there is danger to life.

The inadequacy of the usual methods of estimating the heart's inefficiency was commented on and attention to symptoms which occur in early stages shown to be of great value. Many such symptoms, said the lecturer, are ignored and few properly understood. He then gave a full account of the strictly practical way in which he insists on patients describing their sensations and all attendant circumstances. A special inquiry should ascertain what effort a person can undertake without discomfort. If any limitation of the work force be indicated search must be made as to all the possible factors which may produce exhaustion. The only real test of the integrity of the heart-muscle is its power to respond to effort without distress.

Recognizing that exhaustion of the heart was due to an insufficient period of rest, the lecturer reached the great indication for treatment—that a person with diminished work force must live within the limit of his powers, for in this way alone can failure be postponed and the individual attain reasonable longevity. This essential of treatment—rest—is self-evident and generally acknowledged, but the lecturer seemed to think not sufficiently appreciated. The reputation of digitalis and its congeners rests on its power of slowing the pulsations and that entails increasing the rest. Baths, exercises of a special kind are often prescribed but are opposed to rest and only of use for some anomalous condition—not for threatened failure. Dr. Mackenzie repudiates the common belief in strychnine and the almost superstitious faith of those surgeons who will not operate until after the "preliminary ceremonial rite of a hypodermic injection" of it. He has sought in vain for the slightest evidence of any effect on the heart of medicinal doses. So it is with other drugs and methods which unfortunately too often prevent the appreciation of what is of real service.

Much is heard from time to time about the association of rheumatism and chorea. Dr. Buchanan introduced the subject to the Liverpool Medical Institute in March. He regarded rheumatism as a lingering process with exacerbations produced by the Poynton-Payne organism. Treatment accordingly he directed towards increasing the resistance by means of a vaccine prepared from a streptococcus found in a case of rheumatic endocarditis. He had so treated twenty cases and thought it useful. Dr. Bradshaw (president) thought the bacteriology of rheumatism uncertain and did not consider Poynton and Payne's organism was proved to be the cause. He was satisfied with the salicylates. Dr. P. Marsh said growing pains in children were rheumatism of muscles and fasciæ and should be considered important or heart trouble might occur. He had treated ten cases with *Streptococcus rheumaticus*, of which seven improved considerably but three had returned to hospital with relapses. One case of chorea showed no improvement but developed endocarditis while under treatment.

Dr. M. Bligh found every case of chorea gave a positive tuberculin reaction and quoted the experience of Dr. R. W. Philip that chorea was often associated with tuberculosis. Dr. Davies referred to imitation chorea. Dr. Macalister had no doubt that chorea was infective and related cases illustrating this. As to rheumatism he felt some doubt. He had formerly pointed out that immunity between the two affections was not such as should be if they were due to one toxin. In 1902 he had stated that sodium salicylate was like a chemical test for acute rheumatism and cases which did not respond to it were rheumatoid. Eosinophilia was constantly present in chorea, but never in rheumatism. This blood condition continued for some time after the patient seemed well, but while it existed relapses might be expected. Therefore he kept hospital patients in until the blood became normal.

The President of the Society for the Study of Inebriety, Dr. T. B. Hyslop, in the course of an address on Wednesday, urged the importance of temperance for success in life. He declared that already sobriety was victorious and the public had seen what was injurious. In the learned professions he said alcoholism usually signified mediocrity in personal attainment, and in commercial circles London could tell the tale of inefficiency in every branch. The increasing complexity of machinery and progress of invention required an expenditure of nervous energy and alertness, both mental and physical, unknown to our forefathers. Even the taxicab driver had found he could not afford to drink; one had told him that he had to give up drinking on account of the jolting of the car, as it made him muddled sooner, so he could not control the steering wheel and made him less alert to danger; another driver told him that the old horse used to get him home somehow, but the motor was not to be so trusted. Dr. Hyslop further showed that as in work so in play, alcohol impaired efficiency, and nowadays was distrusted where there was any real desire to succeed or to excel in any capacity.

Dr. F. W. Mott said neurasthenics, epileptics, hysterics, eccentrics, degenerates, and potential lunatics all exhibited marked intolerance of alcohol. Failure to discriminate between such conditions and heredity (a predominant factor in asylum cases) had been the cause of much confusion. A chronic inebriate might be as dangerous to himself and to society as a certifiable lunatic, and when other means failed should be segregated for long periods, whether he would or not. Dr. Sullivan's study of statistics convinced him that alcohol was not so often the cause of certifiable lunacy as was supposed, perhaps not more than 10 per cent. were due to it.

Dr. Jones of the Clayburg Asylum denied that teetotallers were as numerous among the insane as those who took alcohol. In his asylum they scarcely ever came across a teetotaller.

At the Royal Sanitary Institute the subject of "Dirt in Food" was dealt with on Wednesday. Some uninviting illustrations were given of the manner in which, too often, bread, fruit, sweets, meat and fish are exposed to street dust, flies, dirty handling and other modes of contamination. It was asserted that you in New York were much better off because the vendors were compelled by law to protect such things by covers. On this I congratulate you. Dr. Blyth remarked that only certain kinds of dirt were dangerous, but I do not feel that the statement renders the other details dealt with less nauseous. Indeed, an innocent impurity in the toxic sense may be a carrier of the most virulent infective matter. I agree with Prof. Kenward, who said much contamination took place in the homes of the people, and that was a good reason for teaching hygiene in the schools.

The thirty-seventh annual meeting of the Hospital

Saturday Fund was held at the Mansion House on the 8th inst., the Lord Mayor presiding. The report which showed the distribution last year of £32,439, an increase of £4,327, was adopted, after which Mr. Eason, Sr., ophthalmic surgeon at Guys Hospital, spoke in support of the action of the fund in assisting those in need of treatment for the eyes. He told the members that more than half the blind lost their sight in the first year of life through preventable infection. Most diseases of the eye were caused by insanitary surroundings, children herded together in rooms and using the same towels and clothes. If dirt-disease were removed the ophthalmic out-patients at hospitals would decrease more than half. Trachoma was being spread in England by the admission of aliens affected with it, and he was sorry to see the rejections of alien immigrants were only a quarter as many as the previous year. This could not be from their improved health, and he feared it was due to relaxation in examining them.

Dr. Wm. W. Macreight, consulting physician to Torbay Hospital, has died at the age of 83. He took his M.R.C.S. in 1849 and M.D. Glasgow 1850. He joined the College of Physicians of London as member in 1859.

The death of the eminent geologist, Mr. Rupert Jones, took place yesterday at the age of 91. He was originally intended for the profession and served an apprenticeship on the former plan to a surgeon and also did some hospital work. But his appointment as assistant secretary to the Geological Society in 1850 determined the career in which he has won so distinguished a place.

Dr. H. J. Stokes, well known in North London, has died at the age of 88. Took M.R.C.S. in 1843 and M.D. Edin. two years later.

OUR VIENNA LETTER.

(From Our Regular Correspondent.)

CLINICAL VALUE OF DETERMINATION OF CARBON DIOXIDE IN THE BLOOD.—SULPHUR IN THE URINE IN CARCINOMA.—RARE DISEASE OF THE ESOPHAGUS.—DEATH OF PROFESSOR ESCHERICH.

VIENNA, April 1, 1911.

THE relationship between the alkalinity of the blood and respiration has been investigated by Leimdörfer, Porges, and Marcovici. The maintenance of the alkalinity of the blood as a constant quantity is dependent upon the normal course of the chemical processes in the body. This regulation is brought about by three factors: The kidneys rid the organism of the acid products of fatty and albuminous metabolism; the liver neutralizes abnormal acids by means of ammonia; and the lungs eliminate carbon dioxide. The last is contained in the blood, partly in chemical union and partly in loose physical combination, in which case it is capable of being given off in the lungs. The respiratory center is sensitive to the carbon dioxide content of the blood, and is adjusted to a certain percentage of carbon dioxide. Under abnormal conditions, associated with disturbances of metabolism and the production of abnormal acids, the content of carbon dioxide in the blood is disturbed. The more these abnormal acids are present in the blood the less carbon dioxide is necessary to stimulate the respiratory center. It may be stated in general that the latter reacts to all acids, carbon dioxide being only a special stimulus. Breathing is a regulation of the alkalinity of the blood. The above named investigators have studied the carbon dioxide content of the blood in various diseases, and from this have concluded the presence of abnormal acids in the blood. According to electrometric methods the reaction of the blood is almost always neutral, or slightly acid, while the titration methods, which do not take account of the carbon dioxide, show an alkaline reaction. The investigators employed the method of determining the carbon dioxide in a cabinet connected with the lungs; the patient is made to expire into a rubber bag. Marked variations in carbon dioxide, which is a weak acid, gave but slight differences in the analysis. In diabetes mellitus it was found that acidosis, due to the production of abnormal acids, reduces the acid-binding power of the blood, which cannot take up as much carbon dioxide as in the normal state. The administration of sodium bicarbonate restores the alkalinity of the blood. The variations in the carbon dioxide content go hand in hand with the degree of acidosis, so that the determination of the carbon dioxide content may indicate the approach of diabetic coma. The normal content of carbon dioxide in the blood is 6 per cent. In a case of diabetes this was 4.3 per cent.; at one time it sank to 3 per cent., but upon the administration of 25 grams of sodium bicarbonate it rose to its former figure, with the improvement in the patient's general condition. The new method requires but ten minutes for its determination, while urinary examinations for the same purpose require a whole day, which may delay proper therapeutic measures. After a meal the carbon dioxide percentage of the blood increases. If the functional power of the kidneys is embarrassed, the acid end-products of fat and proteid metabolism accumulate in the blood, and the carbon dioxide content sinks; this reduction is also found in carcinoma. In diabetes the abnormal acids are oxybutyric and diacetic acids; in nephritis they are acid phosphates, while in carcinoma these acids are not yet determined. In cardiac dyspnea the carbon dioxide content is diminished and oxidation is incomplete; lactic acid has not been detected in this condition.

Dozent Hans Salomon, and Paul Saxl found in the urine of cases of carcinoma a sulphur reaction. They detected an increase in oxyprotein acids, which did not finally produce oxidized albuminous bodies. By means of perhydrol one can oxidize the neutral sulphur of the oxyprotein acids with the formation of sulphuric acid. Of 79 cases the reaction was positive in 59. This reaction is found also during pregnancy, and in cirrhosis of the liver.

In the Practitioners' Society, Dr. Hans Heyrovsky demonstrated a rare disease of the esophagus. The patient was a woman 34 years old, who, ever since she was 19 years old, suffered from vomiting after every meal. Later when she attempted to suppress the vomiting she also experienced attacks of pressure in the region of the sternum, cyanosis, and dyspnea, which attacks disappeared whenever repeated belching or vomiting occurred. In the medical division of Professor Pal a disease of the esophagus was diagnosed. The patient had on two occasions profuse hematemesis; her attacks of dyspnea were accompanied with intense cyanosis, distention of the jugular veins, and swelling of the thyroid. These attacks subsided with the regurgitation of air. During the act of swallowing she swallowed air in order to press downwards the contents of the esophagus; the accumulation of air in the latter, as revealed by the *x*-rays, caused severe respiratory difficulty, owing

to pressure upon the trachea. Radiographic investigation by Dr. Holzknecht showed that the esophagus formed above the diaphragm an S-shaped tube, with a diameter of two finger breadths, which made it impossible to pass a sound into the stomach. From the esophagus it was possible to remove 500 c.c. of fluid mixed with food remains, in which there was no free hydrochloric acid, although it contained lactic acid. The patient was transferred to the surgical service of Professor Hochenegg, and last June a gastric fistula was established in order to nourish the patient better, and in order eventually to dilate the cardia by way of the gastric fistula. The latter procedure did not succeed; accordingly, last December a second operation was performed. This consisted in drawing the esophagus so far below the diaphragm that one could perform an anastomosis between the esophagus and the fundus of the stomach. Even the normal esophagus can be drawn below the diaphragm, as may be demonstrated in the cadaver; in this case this was still easier, since the esophagus was elongated. The result was a favorable one. Convalescence was complicated by a left-sided pleurisy. The patient can now swallow any kind of food without difficulty. Heyrovsky believes that this case was one of peptic ulcer of the cardia, with spasm of the latter, and with the later development of a stenosis, which controlled the clinical picture. All former instances of anastomosis between the esophagus and the stomach have ended fatally.

Hofrat Professor Theodor Escherich died February 15 from cerebral hemorrhage. He was born in 1857 at Ansbach, in Bavaria. He received an exceptional training as assistant to the famous internist, Gerhardt, and later in the Munich pediatric clinic, which at that time was under the direction of Ranke. At the early age of 33 he was made chief of the children's clinic at Graz. In 1902, on the death of Widerhofer, he became director of the pediatric clinic and of the St. Anna Children's Hospital in Vienna. Escherich's development was concerned chiefly with bacteriological and clinical studies. He became famous as the discoverer of the colon bacillus. He was also noted for other important bacteriological investigations. Escherich discovered and delineated several diseases: cystitis in infants, streptococcus enteritis, colon bacillus colitis, all of which have been valuable contributions to pediatrics. One of the favorite studies of Escherich was that of tetany, whose characteristics and further study have been worked out in Austria. Besides, Escherich was interested in infant feeding, and, within recent years, in the diagnosis and treatment of infantile tuberculosis.

Acute Postoperative Dilatation of the Stomach. R. T. Morris.
An Analysis of Forty-six Cases of Prostatectomy. L. Davis.
A New Tonsil-Seizing Forceps. L. Arkin.

Scoliosis.—R. Soutter describes his method of treating cases of scoliosis in which there are marked structural change and rotation, in which absolute correction of the curve seems practically impossible. After a thorough course of flexibility and muscular work in corrective machines, increasing the strength, endurance of the patient, and pliability of the spine, machines on and in which the patient is placed are then used for decreasing the rotation and curve. These machines enable the surgeon not only to get the most effective correction without overtaxing the endurance of the patient, but adapt the patient gradually to the pressure, which later on it may be necessary to apply constantly. A corrective day and night apparatus is used, followed in two to four months by corrective apparatus made from a cast representing the maximum amount of correction the patient will stand, applied with head traction and side and rotary pressure by means of apparatus. The patient may be kept recumbent in the last appliance. Later the cast is remodeled and trial apparatus applied and altered as may be necessary. Such apparatus is changed to suit the condition every two to four weeks or six weeks, depending on the rigidity of the spine and the condition of the skin at the points of pressure.

Acute Postoperative Dilatation of the Stomach.—E. W. Lee regards this condition as a neurosis, some serious vasomotor nerve disturbance rather than any direct irritation of the stomach itself. The stomach is dilated sometimes to its normal capacity, but often extending into the pelvis. The condition is diagnosed by inspection and palpation, and the various lines of symptoms which accompany it. It usually comes on anywhere from one hour to twelve to fourteen hours after the operation. The earlier symptoms are apparently those extreme shocks in which intolerable vomiting occurs. The contents of the stomach are followed by expulsions of glairy mucus, and, if the vomiting continues, of mucus streaked with blood. Aside from the vomiting, the surgeon's attention should be attracted by the rapid and constantly increasing pulse. The symptoms are often allied to those of internal hemorrhage, but this complication can usually be excluded by taking into consideration all the details of the operation. The treatment is to relieve shock and to sustain the patient. Irrigating of the stomach is primarily indicated. The drugs indicated are, first, morphine, to relieve pain and shock, and, next, strychnine to stimulate the heart's action, the vasomotor system, and the involuntary muscles.

Acute Postoperative Dilatation of the Stomach.—R. T. Morris states that this condition presents four salient features: (1) The initial disturbance, (2) increased peristalsis and antiperistalsis, (3) great dilatation of the stomach walls, (4) extreme amount of secretion. Shock, ether and toxins overstimulate the sympathetic nerves, which overstimulation has the same result as cutting the vagus, which is known experimentally to lead to enormous dilatation of the stomach. Shock, ether, and toxins all derange the action of the hormones with consequent loss of control of the secretory glands: this accounts for the vast quantities of fluid in the stomach in these cases. What is to be done for the cases of acute gastric dilatation? Place the patient upon the abdomen, inclined a little to the right side. That will mechanically compress the dilated stomach and unkink the duodenum. Wash out the stomach every hour or two if necessary with the stomach tube. That allows the postural mechanical resource to become more effective, and it takes away saprophyte poisons. Many of these patients will progress steadily toward recovery from the very moment of application of these two simple resources.

Prostatectomy.—L. Davis continues his analysis of forty-six cases of prostatectomy.

Tonsil-Seizing Forceps.—L. Arkin describes a new instrument of this kind which is simple and effective for its intended purpose in the operation for the enucleation of the faucial tonsils with the cold snare.

Starnook and Window Tent.—S. A. Knopf describes a new and practical device which will answer all purposes for outdoor life by day and by night. The starnook may be built on an extension at the rear of the house, but it may also rest on posts or columns, or triangular supports attached to the walls. The starnook consists of three walls composed of frames holding movable slats, of a roof, and a floor. It is all made of galvanized iron with the exception of the floor, the window sash, and the roof frame. The wall of the house closes the fourth side, through which access is had to the starnook by a long window or a door. It is about 9 feet long, 6 feet deep, 6 feet high at the outer side, and 8 feet next to the house. It can also be made 8 feet deep, and will then hold a bed and couch or two beds. The roof can be completely raised against the wall of the house and an unobscured view of the sky can be had by the occupant of the bed. During the day the starnook can be transformed into a typical rest cure veranda. Three upper sections of the front shutters can be entirely opened, and with the two windows open and the roof up one is certainly out of doors.

Significance of the Ring Bodies.—J. Wright notes that the ring bodies that he has found in the tonsil exhibit under certain differentiating processes clear evidence of the existence of certain compound physical states associated with metabolism.

Misuse of the Prostate in Gonorrhea.—H. G. Klotz concludes that the prostate is not affected in all cases of chronic gonorrhea, but that various conditions of the anterior urethra are just as liable to cause the prolongation of the gonorrheal infection. The doctrine that the prostate takes part in every case of chronic gonorrhea is a mischievous and dangerous one, because it will lead to neglect and oversight of the chronic lesions of the anterior urethra, because it favors the indiscriminate application of prostatic massage with the incidental opportunity for spreading the infection of the prostate. Massage of the prostate should be restricted as much as possible, because its popularization is liable to corrupt public morals.

Chronic Backache.—C. Ogilvy discusses the etiology of a few forms of backache, which are frequently seen and less frequently recognized. These are the cases of weak spine with postural deformity; rotary lateral curvature (scoliosis); sacroiliac strain, and flat feet. Chronic backache from these causes is so frequently overlooked.

Psychogenetic Convulsions.—H. W. Frink reports the case of a woman of twenty-three years, with a history of petit mal attacks from her second to her fourth year; grand mal attacks, from four to twenty a month, from the fourth to the twenty-third year, with hallucinatory attacks, and compulsive ideas. Treatment by suggestion produced immediate and almost complete relief for a period of eleven months.

Pepsin and Diastase in Urine.—E. H. Goodman is of the conviction that no diagnostic aid is to be sought in the amount of pepsin or diastase in the urine.

Breaking Down of Wounds.—J. J. Gilbride notes the conditions that favor the breaking down of wounds following operations. Infection is the primary cause to which a number of factors contribute. The preparation of the hands of the surgeon, assistants, and nurses, and suture materials, dressings, etc., have received a great deal of attention. The iodine method of preparing the abdomen for laparotomy is the most important development along this line. The surface of the wound should be protected from infection when a hollow viscus is opened. Bleeding favors infection, hence all bleeding should be properly controlled. Dead spaces in wounds should be obliterated. The least amount of traumatism inflicted on any tissue the more likely is it to heal promptly. The use of large sutures and large knots is undesirable, as is also the use of unabsorbable sutures.

Microorganisms in Rabies.—F. Proescher found in smears taken from the brain of dogs infected with street virus microorganisms which are resistant to a fifteen per cent. solution of antiformin. The smears showed Gram stained, nonacid, resistant microorganisms in form of bacilli, one-half to one micron in length and one-third micron thick, and either isolated or arranged in chains or groups. These bacilliform microorganisms were similar to those described previously in the smear of fixed virus, except that the latter were finer and paler Gram stained. Besides these small bacilli there were larger, oval, or round forms, which were arranged in pairs, chains, or groups. Also a granulated bacilliform was found.

The Impure First Sound at the Cardiac Apex.—S. Neuhof reports cases which are cited because they strikingly illustrate how little, besides an alteration in the first systolic sound, remains after severe attacks of acute dilatation. In every instance the patient was quite ill during acute attacks of what might be called typical heart failure, and yet, after a longer or shorter time, sometimes only after a few hours, at other times, after months, the heart functionally returned to the normal and regained its "tone"; all evidences of severe dilatation and heart weakness had vanished, dyspnea, edema, bronchitis, and loud murmurs had disappeared, the patients went about their usual work (in many instances hard manual labor), and only very careful and perhaps repeated examination showed any physical abnormality in heart action or heart sounds. The alteration in the first sound consists in a slight or marked diffuseness, a spitting or break in its continuity, an indistinctness, as a faintly perceptible murmur.

Animal Experiments and Obstetrics.—J. W. Williams states that puerperal fever, which formerly carried off about one in thirty of all married women, even within the last fifty years, is now a comparatively negligible cause of obstetric mortality. The application of aseptic technique to obstetrics is shown to have been the result of the acquisitions obtained by vivisection, the mortality from puerperal infection in well regulated hospitals being at present less than 0.25 per cent., as contrasted with the average mortality of 3 or 4 per cent. throughout the world before the introduction of aseptic methods. The various operative procedures in obstetrics and their safety in recent times

are well illustrated by the history of cesarean section, and exactly the same story can be told concerning the results following the operations of symphyseotomy and pubitomy. One also owes to vivisection the recognition of the bacterial nature of the diseases of the new-born child which formerly caused a large mortality. At present every child-bearing woman who has the benefit of the action of ergot during confinement has the benefit of at least one of the advantages which have been gained from animal experimentation. Another important acquisition is that of the knowledge of the internal secretion of the ovaries and the consequences of its suppression. Still another has been gained by the investigations of experimenters with animals on the origin and nature of the toxemias of pregnancy. While the subject of eclampsia has not yet been thoroughly cleared up, it is only by animal experimentation that one can ever accomplish it. Our knowledge of the production of fetal deformities is due to the same source.

Stuttering.—E. W. Scripture states that laryngeal cramps are a never-failing symptom and it is not unusual to find a patient who never has another symptom in the presence of a physician than the monotonous laryngeal tone of voice. Cramps and spasms of the muscles of enunciation are the ones most apparent to the observer, and less frequent but more striking are the contractions of muscles not usually used in speech, such as those of the neck or eye or other parts of the body. An almost constant symptom is excessive rapidity of speech, indicating sometimes a desire of the stutterer to get his words out before he is caught, or in other cases an expression of nervous anxiety. A never-failing symptom is lack of confidence in the patient's power of speaking correctly and this is sometimes sufficient to make it impossible for him to enunciate certains words. The simplest form of stuttering is that of pure habit, due sometimes at first to imitation, but stuttering almost always goes beyond the habit stage. The curative treatment is based on the principle of correction of the abnormal voice that almost always exists. The patient does not usually stutter when singing or otherwise using his voice in an unusual way and he can be trained to speak in some sort of an odd voice. This is the method of the stammer schools and stutter cures and is not usually permanently effective. The essential point is that the stutterer should feel his acquired speaking voice to be that commonly used by him. There is another way of speaking that is unusual to the stutterer, *i.e.* the way in which normal persons speak, and the therapeutic procedure on this principle therefore will be to teach him to speak normally. The "principle of habit formation" implies that the new way of speaking is to be drilled into the patient so as to become a habit. The "principle of spontaneity" is requisite because when the patient has learned to speak perfectly he may still be unable to do so when he speaks of his own accord. In the beginning his exercises may be made privately but later with a gradually increasing number of strangers. The "principle of correct thinking" is that the abnormal habits of thought which the stutterer always acquires to some extent are to be corrected by appropriate exercises.

Globulin in Cerebrospinal Fluid.—S. Strouse concludes that tests for increased globulin in the spinal fluid are easier to perform than is the total cell-count and have practically the same diagnostic importance. The butyric acid test of Noguchi is convenient and accurate. The use of this reaction gives information of considerable value in diagnosis. The reaction is positive in general paralysis and cerebrospinal syphilis; negative in brain tumor, cerebral arteriosclerosis, and psychoses. A positive reaction in a doubtful nervous case is presumptive evidence in favor of the diagnosis being a syphilitic or parasyphilitic disease of the nervous system. In tabes dorsalis the author's results are not in agreement with previous reports, the reaction being present in only 33.33 per cent. The reaction is positive in all cases of acute meningitis and absent in meningeal irritation without actual inflammation. It is always present in tuberculous meningitis, and its presence is an aid in the diagnosis. The absence of the reaction in cases of suspected tuberculous meningitis is of great value in excluding meningitis.

Cancer of the Cervix.—P. Findley states that one cannot cure these patients, but one can relieve suffering and give them added days of comfort and usefulness. The curette and cautery are still in use, and the author is not disposed to discard them. They have proved a positive value in his hands. For the past six years he has followed the practice of packing the excochleated and cauterized area with gauze wrung out of a 1 to 4,000 aqueous solution of 40 per cent. liquor formaldehyde and following such a procedure bloody and odorous discharges have disappeared for from two to four months. He quotes Gellhorn's description of his acetone treatment and believes that this is a valuable remedy in inoperable cervical cancer.

Exophthalmic Goiter.—H. Dayton states that the few recorded results with thyroidectin in exophthalmic goiter are, on the one hand, improvement in 100 per cent. of thirty-six cases reported by three writers; on the other, one unfavorable report on twelve cases, one of negative results in a single case, and general condemnation, without details, by three observers. To these the author adds five cases, none of which gave results which were greater than the ordinary variation in symptoms in exophthalmic goiter under the influence of rest, suggestion, and regulation of habits, while in one case the remedy appeared to aggravate the symptoms. Two patients treated with desiccated milk of thyroidectomized animals showed extreme aggravation of symptoms in one case, apparently a direct result of the treatment, and in the other improvement, probably due to restriction of coffee. The results of treatment with thyroidection seem far inferior to those secured by rest, symptomatic medical treatment, or partial thyroidectomy.

Brain Tumors.—L. Newmark, H. B. A. Kugler, and H. M. Sherman report a case of cerebellar tumor with rather puzzling symptoms in which the patient was greatly benefited by puncture over the cerebellum on both sides, made for diagnostic purposes. The symptoms continuing, however, operation was performed, but revealed no tumor; this, however, was found by enlarging the opening on the left side. A noteworthy point was the nonrecurrence of papillitis with the return of the other symptoms after their disappearance with the diagnostic puncture.

Acute General Peritonitis.—A. D. Bevan discusses the treatment under four heads: (1) The saline cathartic treatment advocated by Tait, which is really of value, not for peritonitis, but for one of its common results, paralytic ileus. (2) The rest and starvation treatment of Ochsner, which is of value not in general peritonitis but in local peritonitis, to prevent its becoming general, and also in the management of a case of peritonitis after operation. (3) Blake's operative treatment shows the power of the peritoneum to protect itself against pus infection. (4) The Murphy method, which emphasizes the importance of tubular drainage and condemns irrigation of the peritoneal cavity, insisting, however, on continuous irrigation of the rectum with normal salt solution and the extreme Fowler position, is largely employed in this country, and the remarkable results obtained by Murphy are strong recommendations. The author thinks that all these methods have their use in certain cases, and offers a fifth one, which he considers the best combination of all the essentials.

Endoaneurysmorrhaphy.—G. S. Crabtree reports a case of traumatic popliteal aneurysm due to gunshot wound, operated on successfully by endoaneurysmorrhaphy. There was immediate restoration of circulation

to the leg and the patient was at work a month after the operation, with apparently normal circulation.

Simplified Stain.—L. S. Medalia describes a simplified staining method to be used in place of Loeffler's methylene-blue and of Leishman's or Wright's blood-stain and in the staining of capsulated bacteria.

Late Pregnancy.—C. C. Norris reports the case of a woman, aged fifty, who had been twice married but had had no children, though she had been operated on after each marriage by dilatation and curetting and simple dilatation of the cervix without results. Menstruation had continued, usually with but slight discomfort. She had never had severe dysmenorrhea. The genital organs were rather normal though the os was small. Dilatation was performed and a rather thick Wiley drain inserted ten days before the expected monthly period. The Wiley drain is a sort of groove-stem pessary. Pregnancy followed, with normal labor and delivery. The advanced age is of interest in this case, though menstruation is not uncommon after the age of fifty.

Syphilis of the Turbinates.—J. W. Jervey states that the only cases of nasal syphilis which are usually promptly recognized on clinical examination are those that are first seen in the tertiary stage, when gummatous and necrotic processes are extensive. Hypertrophy of the turbinates in secondary syphilis shows only the symptomatology of hypertrophy due to other causes, and ulceration may occur as the result of pressure or nutritional errors in other diseases. The old-fashioned therapeutic test is the best.

Nasal Secretion in Poliomyelitis.—I. Strauss reports experiments that seem to indicate the absence of the virus of poliomyelitis in the nasal mucus.

Etiology of Verruca.—D. W. Montgomery states that moist heat, inducing maceration of the epithelial cells is one of the most important predisposing causes, probably by exciting the epithelial cells to grow more luxuriantly, especially when an injury draws an increased supply of blood to the part.

Apparatus for Intravenous Injections.—W. F. Bernhart describes a simple apparatus for intravenous injections by means of a pressure bottle.

Some Common Forms of Deafness. W. H. Kelson.

Heart Failure.—J. MacKenzie states that, according to the bodily requirements, the force inherent in the heart muscle may be considered for practical purposes to be composed of two parts—namely, a part which is employed to maintain an efficient circulation when the body is at rest, and which, therefore, may be called the "rest force." The second part of the heart's force is that which is called upon when the body makes some effort. Heart failure invariably starts in the first instance by exhaustion of the work force. The exhaustion is slight at first, but by the persistence of the causal factors it proceeds until the exhaustion induces such distress as to compel attention, or the rest force is encroached upon, and with the exhaustion of the rest force a point of danger to the life of the individual is reached. Heart failure is no more than the inability of the heart to regain sufficient work force during its period of rest. When exhaustion sets in the first sign is given by some sensation of distress. This sensation arises by calling into play some part of the nervous system. The sensations may be of varied character, as a sense of exhaustion, choking sensation in the throat, tightness across the chest, dyspnea, or pain. When such sensations arise during effort they act as an imperative call to desist from further exertion. The standard by which the heart's strength is measured is peculiar to the individual. The simple test is to observe how the heart responds to effort. Many individuals suffer from extreme heart failure who never show any objective sign, the heart's action and size agreeing in every respect with one's conception of what is normal. But if this method of estimating the condition of the work force be followed symptoms of a characteristic kind will be found that will show the extent of the heart failure, and warn the physician when danger is impending. When one reflects as to what are the essential conditions which lead to heart failure one will at once recognize the great limitations of all methods which depend on the use of mechanical contrivances. The early subjective symptoms of heart failure are breathlessness, pain, hyperalgesia of the external body wall, the sense of compression of the chest, and the feeling of suffocation in the throat. These phenomena when present singly or two or more together are frequently the only grounds on which a safe opinion can be based. The patient should describe his own sensation and all attendant circumstances minutely. One should ascertain if he can do the work and effort of a healthy man at his time of life. If he can do this one should give him a good prognosis. A careful investigation may reveal that excessive work, worry, or sleeplessness has prevented recuperation. On the other hand, other factors may have contributed to the heart's embarrassment, such as poisoning from tobacco or alcohol. By the removal of these causes the heart may be restored to such efficiency that the individual leads a useful life at a lower level, with a prospect of attaining the allotted span. Auricular fibrillation not infrequently induces an extreme amount of heart failure, which may speedily terminate in death. An individual affected by a heart lesion which diminishes his work force must live within the limits of his powers. It seems probable that drugs which have such a potent and beneficial effect upon the heart as those of the digitalis group owe their good effect mainly to the amount of rest procured by the slowing of the heart's rate. Practically all recorded cases illustrating the remarkable effects of digitalis are cases of auricular fibrillation. There is no evidence of the slightest benefit of the effect of medicinal doses of strychnine upon the heart. There are many conditions in which rest alone fails to benefit the heart, as when the heart is invaded by a toxin, or rendered irritable from some lesion in the heart itself, or when the ventricle in heart-block contracts so seldom as to endanger life.

Cesarean Section.—By A. Routh. See MEDICAL RECORD, April 1, 1911, page 593

Skeletal Changes in Acromegaly.—A. Keith, as the results of his investigations of the comparative anatomy of the skull, concludes that the changes in acromegaly are of the nature of true growth, and are apparently due to the circulation through the body of a substance formed in the pituitary. This substance seems only to sensitize the tissues, the actual cause of their growth being mechanical stimuli arising from muscular action and mechanical movement. The growth changes seen in the acromegalic are of the same nature as those which occur normally in anthropoids and in the Neanderthal race, and both are probably due to a condition of hyperpituitarism.

House Epidemic of Typhoid Fever.—W. J. Wilson and J. A. Sinton report a house epidemic consisting of seven cases of typhoid fever. The first case was the

mother, who had eaten cockles a fortnight before her illness and who became a carrier. The infecting bacillus was at first immotile when grown on agar, and was somewhat inagglutinable. The mother gave birth to a healthy full-term child, and her milk was very rich in agglutinins.

General Anesthesia Combined with Narcotics.—G. Brown reports his experience in 300 cases of general anesthesia combined with narcotics. The general anesthetics used were ether, chloroform, ethyl chloride, mixtures of chloroform and ether in different proportions, the A. C. E. mixture and sequences of different anesthetics. The narcotics used were morphine combined with atropine, hyoscine and scopolamine, veronal, chloral, and bromides. The effects of the narcotics were greater tranquility of the patients before operation; the anesthetic was taken better; the induction of anesthesia was quicker; the amount of anesthetic used was less; salivation and excess of mucus were rare; postanesthetic vomiting rarely occurred; shock and postoperative pain were lessened. The combination of narcotics found most satisfactory was morphine, ¼ grain, hyoscine or scopolamine, 1-100 grain, and atropine, 1-100 grain.

Prolapsus Uteri.—J. O'Conor describes his method of ventrifixation by means of which the denuded cervical connective tissue is brought into direct apposition with the recti. The operation is working on anatomical lines in that it leaves the naturally mobile fundus free, and reinforces the immobility of the cervix, which is supposed normally to be comparatively fixed, and which is vouchsafed by all anatomists as being the keystone of support for the pelvic organs.

Common Forms of Deafness.—W. H. Kelson states that these are due to impacted cerumen, furunculosis of the external auditory canal, a foreign body in the meatus, suppuration in the middle ear, chronic middle ear catarrh, otosclerosis, disease of the internal ear ducts, syphilis, malaria, gout, and other diseases tending to produce variations in the intralabyrinthine pressure.

Evidence of Recent Severe Illness Afforded by the Nails. N. Flower. With a note by Sir Samuel Wilks.

Arteriosclerosis and the Kidneys.—Sir Clifford Allbutt notes that albuminuria in cases of arteriosclerosis must not be taken alone as evidence of Bright's disease, nor necessarily as a foreboding of it. In shrunken kidney, whether small white or red granular, the arteriosclerosis, even if restricted to the renal arterioles alone, is arteriosclerosis proper—that is, subintimal hyperplasia with splitting of the internal elastic layer. Renal arterial disease does not differ from arteriosclerosis elsewhere, as generally recognized by modern observers. If renal disease without arterial disease, discoverable at any rate by the microscope, is rare, yet there is no arterial disease peculiar to the kidney. And generally in renal disease the state of the arteries is arteriosclerosis: yet there are at least two other forms of change in them which need some discrimination—namely, endarteritis obliterans and the hypertrophy of the media alleged by Johnson, Ewald, and Savill. The affections of the arteries in the kidney are: 1. Arteriosclerosis, which is the frequent alteration. 2. Endarteritis obliterans, an incidental and secondary condition. 3. Thick media, perhaps a hypermyotrophy (?). 4. Infective processes, such as the scarlatinal, the syphilitic, etc., attacking the vessels. And to these classes may be added the accidental processes of infarction and of embolism. One may conclude that of the red granular kidney arteriosclerosis is a primary, invariable, and essential part, and presumably begins in the intimate vascular ramifications; although an arteriosclerosis of the larger vessels may be an epiphenomenon, due to prolonged high tension, and appear later.

Heart Failure.—By J. Mackenzie. See abstracts of articles in the *Lancet*, April 15, 1911.

Surgical Treatment of Chronic Colitis.—D'Arcy Power notes that chronic colitis may be due to simple irritation of the bowel, protozoal infection, or bacteria. There are a large class of cases which are grouped under the comprehensive heading of "ulcerative colitis," although there is no doubt that several subclasses of the disease exist. In these cases the large intestine may be ulcerated locally, or the inflammation may extend throughout its whole extent. The lesion is chronic, destructive, and generally extensive. It rarely leads to perforation of the bowel; it is hardly ever associated with abscess of the liver; it kills by toxemia. It occurs equally in men and in women, and although it occurs in epidemics, it is usually sporadic, as one sees it in private and in hospital practice. The actual cause of the ulceration is unknown, although in several of the author's cases it has followed parturition, piles, fistula, and fissure. Castor oil and irrigation of the rectum are excellent methods of treatment at first, but more heroic means must be adopted if the conditions do not improve quickly. Foremost among these comes vaccine therapy, the vaccine being made from the particular strain of microorganism which is causing the inflammation. Death from toxemia is the great danger of the disease, and if the patient is to be rendered immune the earlier the process is begun the more likely are the results to be satisfactory. It is important, therefore, to cleanse the bowel and to keep it free from putrefying products. Drainage through the appendix enables this to be done in the most satisfactory manner. The operation of appendicostomy is not so serious as that required for removal of the appendix during the quiet stage. It is very effective, and the fistula can afterwards be closed without trouble.

Vaccines in Acute Mastitis.—T. H. C. Benians states that in the class of cases in which direct infection from a nipple lesion has occurred, either with a streptococcus or a streptococcus and *Staphylococcus aureus* together, judicious vaccine treatment will have a favorable influence. Suppuration may be prevented and the whole condition may clear up rapidly. In the class of cases in which no external lesion can be found to account for the infection the same favorable results may be obtained. Pus, if present, should be evacuated and good drainage should be established.

Erythema Nodosum Following Measles.—E. P. Joynt reports nine cases of erythema nodosum that occurred during an epidemic of measles. In most of the cases about ten to fourteen days had elapsed since the first onset of measles before the erythema nodosum made its appearance. In half the cases the first symptom was pain in the joints, followed by the erythema in about 24 hours. There was no history of rheumatism or contact with rheumatic fever in any of the cases, and no rheumatic or cardiac lesions were found in any of the patients.

Surgical Treatment of Pulmonary Cavities.—J. D. Harris reports the case of a patient in whom a bronchiectatic cavity was successfully treated by incision and drainage.

Scopolamine-Morphine in Labor.—D. Corbett concludes that the scopolamine-morphine combination is of great value where hysteria and distress are manifest during the first stage of labor. If possible it should only be given in the first stage and not repeated. No ill effects to

the mother need be expected even with full and repeated doses. No ill effects need be expected for the child, even where the mother has had full and repeated doses, provided that delivery does not take place at four hours or less from the time of the last dose, otherwise apnea will ensue. On the other hand, where the drug is without effect on the mother it is not likely to affect the child, even if born within four hours. The cause of the apnea is probably the morphine, and so where it is necessary to give the drug late in the first stage, or early in the second, the morphine should not be given in larger doses than one-sixth grain, or omitted. A hot bath is the best treatment for the apnea. Strychnine may prove to be a useful addition to the mixture. It does not diminish the analgesic effect of the combined drug, and it may help to prevent the apnea in the child.

Recent Illness and the Nails.—By N. Flower and Sir Samuel Wilks. See page 820.

Berliner klinische Wochenschrift.

April 10, 1911.

Extirpation of a Cavernoma of the Liver.—Israel calls attention to the infrequency with which such cases come to operation, this being due to their benign character. But six cases are on record. The author's case makes seven, and differs from the preceding in that it was diagnosticated in advance of operation, the others evidently having been discovered after laparotomy. The patient presented a tumor of the left lobe, readily visible and palpable, in the region between the ensiform cartilage and the umbilicus. Upon pressure with the flat of the hand the tumor was slowly effaced, reappearing after some minutes. This phenomenon was regarded as pathognomonic of cavernoma of the liver. The details of the operation present nothing novel, being such as occur in hepatectomy for any cause. The wound healed by first intention, and patient made a good recovery.

Sarcoma Originating in the Surface of a Lupus Carcinoma.—Senger relates a case of this extraordinary association, which he had previously mentioned in a discussion some years ago. He also alludes to what has been said by others on similar associations, and sums up as follows: It has been shown that sarcoma has formed in the scar of cancer which has healed under radiography. As sarcoma cannot be formed from specific cancer cells it must arise, under such circumstances, from the connective tissue of the scar. The formation of epithelioma upon lupus vulgaris is, of course, sufficiently common to justify the use of the term lupus epitheliomia, for which the author appears to prefer to substitute lupus carcinoma. Hence radiography of this mixed formation might readily, in theory, produce a sarcomatous proliferation of connective tissue. This is what actually occurred in the author's case. The patient, only twenty-four when the cancer developed, had had lupus hypertrophicus of the face for many years. The epithelioma appeared as an ulcer upon one of the lupus lesions, which latter were disseminated over face and neck. The ulcer on the cheek, recognized readily as cancerous, was curetted and treated with the hot air apparatus, after which it healed under röntgenization. All the lupus nodules were similarly treated, but did seem to be radically cured. Over a year later a tumor appeared in the cancer cicatrix and grew with great rapidity, the adjacent lymph nodes also swelling. The first diagnosis of relapsing carcinoma was negatived by the microscopic examination, which showed not a single cancer element, but every evidence of sarcoma. The case soon became inoperable and patient died of exhaustion.

Anaphylaxis of Pregnancy.—According to Hirschberg the anaphylaxis of a pregnant animal to injections of foreign albumin is greater than that of the nonpregnant animal. The albumin thus injected produces a specific reaction, and by directly affecting the vasomotor center causes vasomotor instability. Applied to woman it is possible for this theory to account for the phenomena of the toxemia of pregnancy, eclampsia being the higher expression of the latter. The author does not state the source of the heterologous albumin. The fetus, placenta, and chorionic villi cannot be regarded as heterologous in the ordinary sense.

Münchener medizinische Wochenschrift.

April 4 *and* 11, 1911.

Diathesis and Dyscrasia as Viewed To-day.—Hering discusses this comprehensive subject very briefly. He refers to the cellular and humoral theories at the base of these terms, which are still in use to some extent. To-day it seems better to speak of a normal cellulo-humoral relationship which may be disturbed in various ways, with production of different diseases. Either cells or fluids may be affected singly at first. The subject may be viewed mathematically, using the nomenclature of the differential calculus. Thus C (cell) is a "function" of H (fluids) and vice versa. If C vary slightly there is a corresponding variation in H. In a dyscrasia, then, both solids and fluids must have undergone a change. Dyscrasia is a chronic condition, but it is not primary. Behind the dyscrasia lies a special inborn constitution or disposition—in other words, a diathesis. The author does not cite a single illustration from clinical medicine. He only mentions incidentally the hemorrhagic, uric acid, and exudative diathesis, etc. His thesis seems to be that the terms diathesis and dyscrasia are used synonymously, and that there must be two quite separate conditions included. This confusion is intensified by the use of such terms as disposition and the German *Anlage*. All this is simplified by a division into hereditary tendencies and acquired habits of disease. Certain terms should be reserved for each.

Origin of Pancreatitis in Cholelithiasis.—Arnsperger states that while the anatomy of these structures, including the presence of the common duct, seems sufficient to explain the combined affection in its ordinary phases, it does not account for special conditions, such as the following: a simple cholecystitis with swelling of the head of the pancreas. In this instance it is probable that a lymphangitis transmits the affection from the gall bladder to the pancreas. The latter does not become actually inflamed, but a pancreatic lymphangitis is set up. Carcinoma is known to be propagated in the same way, causing local metastasis in cancer of the gall-bladder. Similar disease phenomena are known, while anatomical studies have established the lymphatic arrangement necessary for such transmission.

Rumpell-Leede Phenomenon in Scarlatina.—Bennecke states that he has confirmed the diagnostic significance of this phenomenon, which is as follows: If a venous stasis is produced in the arm of a scarlet fever patient, the arteries being left alone, hemorrhages appear at the elbow in from five to twenty minutes—punctate or larger, in some cases becoming confluent. This test, positive in nearly 100 per cent., needs a vast amount of study from every point of view before its full importance can be recognized. It is already admitted that the phenomenon has been obtained in other exanthemata, but this fact connects it with the general subject of eruptive fevers, etc. Many of these could be excluded clinically, so that the test would still possess value for scarlatina.

Treatment of the Pestis Pulmonum with Salvarsan.—Schreyer, a practitioner at Tientsin, China, calls attention to the fact that no remedy capable even of acting

favorably on the pulmonary form of the bubonic plague has yet been devised. The mortality is invariably 100 per cent. Haffkin's antiplague serum is inert. He therefore tested salvarsan in one case. The woman had been ill a few hours and her sputum was full of plague bacilli. Salvarsan was given and the disease improved notably, the temperature falling from 40° C. to normal. Nevertheless death occurred 12 hours later from heart failure. The author concedes that patients have lived longer than this one without treatment. In two other women the course was much the same. One of these showed a sputum free from the bacilli, and was able to walk a little. Both were afebrile. The inevitable cardiac failure stepped in despite the use of symptomatic remedies. It is of interest to note that one of these women had a nursing baby which did not contract the disease.

Nephritis in Syphilis Following the Use of Salvarsan.—Weiler records what he believes to be the first cases of nephritis during salvarsan treatment of syphilis. Transitory albuminuria is common, but even in subjects with actual Bright's disease salvarsan has not appeared to aggravate the latter. Two cases of nephritis are given by the writer in detail, while a third occurred after the paper had been completed. The type of nephritis was naturally acute, and the course was a severe one. One is mentioned as being hemorrhagic. One patient was in a somewhat advanced state of secondary syphilis, while in the other the disease was of recent origin.

Intravenous Anesthesia.—Burkhardt gives a rather diffuse account of this subject: He has used the method 250 times and thinks that at least as many more cases could be furnished by others. A great number of substances have been employed. Destructive action upon the blood and kidneys has not been noted. There is evidently some danger from thrombosis and embolism unless a perfect technique is carried out. In the present paper the author confines himself largely to researches by himself and others with old and more recent hypnotics and sedatives. Most of the work done was on animals. The paper is primarily a pharmacological one, and there is little allusion to surgery. The effects produced do not differ in kind from those in inhalation narcosis, but there is naturally a much greater number of substances available for intravenous use.

April 13, 1911.

Diagnostic and Prognostic Significance of Inflammatory Leucocytosis.—At a symposium on this subject held recently in Berlin Grawitz represented the physicians. To estimate leucocytosis at the bedside we must first take into account the activity of the digestive organs and the musculature. Inflammatory leucocytosis represents a reaction of the entire leucocyte forming apparatus, and the leucocytes in the blood represent a defensive mechanism. The strength of the leucocytosis corresponds in the main to the severity of the infection, and is calculated chiefly by the hemolyzing action of the infection upon the red corpuscles. Exceptions, however, occur in which a mild infection causes a high degree of leucocytosis. Hence leucocytosis is of value only when considered in connection with the general condition. In internal medicine its chief field is in febrile affections—whether or not these are due to inflammations. Franz, speaking for the gynecologists, stated that the usefulness of leucocytosis in diagnosis and prognosis was but slight. Sonnenburg, for the surgeons, appears to regard the study of leucocytosis as part and parcel of the general blood examination, and hence indispensable. Many diagnoses have been made through its agency.

Paradoxical Wassermann Reaction.—Rasp and Sonntag refer to the change of the Wassermann from positive to negative and vice versa. They state that this cannot occur when the technique is correct. This applies both to the serum of known syphilitics and that of non-syphilitics. Incomplete reactions cannot be regarded as either positive or negative. These should be marked only as suspicious. The reaction is naturally a matter of perfect technique, and is constantly being subjected to new efforts at standardization. All paradoxal and incomplete reactions should, therefore, lead to criticism of technique.

Chemical Identity of Antibody Formation and Cell Degeneration.—Waldvogel states that study of these two processes shows that the lipoids stand midway in both, and that the fixation of toxins and formation of antibodies are explained by the behavior of the lecithins, fatty acids, and cholesterin. The antibody formation presupposes the degeneration of cells, and the chemical identity of both processes shows us that we are on the right track in looking upon these processes as germane. The lecithins and allied bodies serve as complements, etc., while the newly formed cholesterins neutralize the toxins.

Tin Poisoning.—Günther refers to poisoning from tin cans used for tinning provisions. In 1898 he purchased a can of herrings put up with wine sauce. On account of the paprika, onion, etc., in the sauce no suspicious taste was present. In the night the author was seized with signs suggesting food poisoning, but examination of the fish showed the presence of tin in minute quantities. Meanwhile constipation and a metallic taste had set in. The preservative sauce contained a relatively high per cent. of acetic acid derived from the wine vinegar present, and this had evidently united with the tin. Adulteration of the tin with lead was excluded. Animal experiments show that tin, like lead, produces colic, etc.

Acquired Pelvic Contractions from Severe Labor.—Eduardo Fabbricatore records the observations made by him in his obstetric service in a province of Italy in which there were few roads and no railroads, but in which there were forests and large timber, which was cut and brought to the railroads on the shoulders or heads of the inhabitants. Much of this work was done by women and children, and these often suffered from lack of proper food to sustain such severe toil. In his obstetric service among these women he found many cases of contracted pelvis necessitating operative measures for the delivery of the child. Many cases of forceps, and craniotomy were seen. The author did not do pubiotomy or symphyseotomy on account of the poor and squalid surroundings in which these deliveries took place. He believes that these contracted pelves were due to the severe labor imposed and begun often by young girls at an early age. Up to the age of twenty years the condition of the ossification of the pelvic bones permits of deformities produced by severe labor. The pelvis is supported on two pillars, the femurs, in the erect position. The pressure exercised from above by the trunk and the weights carried on the sacrum pushes the bones into the pelvis and draws inward the upper part of the ilium. The weight of the trunk, the counterpressure of the femurs, and the resistance of the pubes are the three forces acting on the pelvis. The sacrum is pushed deeper into the pelvis, and the curve of the sacrum is exaggerated, thus limiting the size of the pelvis. A torsion of the ilia with flattening of the whole pelvic cavity occurs. The continued action in walking of the exaggerated muscular masses is fatal to the development of the pelvis. Thus result narrow and deformed pelves fatal to normal labor.—*Giornale Internazionale delle Scienze Mediche.*

Book Reviews.

An Anatomical and Surgical Study of Fractures of the Lower End of the Humerus. By Astley Paston Cooper Ashhurst, A.B., M.D., Prosector of Applied Anatomy in the University of Pennsylvania, Surgeon to the Out-Patient Departments of the Episcopal and Children's Hospitals of Philadelphia, Assistant Surgeon to the Philadelphia Orthopedic Hospital, Fellow of the College of Physicians of Philadelphia, of the Philadelphia Academy of Surgery, etc., etc. The Samuel D. Gross Prize Essay of the Philadelphia Academy of Surgery, 1910. Philadelphia and New York: Lea and Febiger, 1910.

This is a valuable monograph dealing with a most important subject in the domain of surgery, namely, recent fractures of the lower end of the humerus. The author shows by a detailed report of cases, accompanied in most instances by skiagraphs, and in many by photographs, that with common-sense surgical treatment, intelligently applied, the prognosis of any and all fractures involving the lower end of the humerus is much less gloomy than it has heretofore been considered and that in the vast majority of cases the ultimate results will be perfectly satisfactory. After a few preliminary remarks on the applied anatomy of the lower epiphysis of the humerus, the author considers briefly the causes, symptoms, and treatment of the typical fractures encountered, and with the addition of personal statistics, shows the results obtained.

Nova Therapeutica. Führer durch das Gebiet der neueren Arznei- u. Nährmittel, zum Gebrauch für den praktischen Arzt. Bearbeitet von Dr. Med. Max Wolf und Dr. Med. Fritz Fleischer. Preis geb. M. 5. Berlin: Vereinigte Verlagsanstalten Gustav Braunbeck & Gutenberg-Druckerei A.-G., 1910.

As its title indicates, this volume is a guide to the newer remedies, giving their mode of preparation, constituents, dosage, and indications. A number of chemical houses have published from time to time books along similar lines. This volume also resembles the work on newer remedies published by the American Medical Association. As a work of reference it cannot fail to prove of great usefulness to the busy practitioner who may desire to avail himself of the most recent therapeutic resources.

Induced Cell-Reproduction and Cancer. The Isolation of the Chemical Causes of Normal and of Augmented Asymmetrical Human Cell Division. By Hugh Ross, M.R.C.S. (Eng.), L.R.C.P. (Lond.), Surgeon Royal Navy (Emergency List), Director of Special Researches at the Royal Southern Hospital, Liverpool, and Honorary Clinical Pathologist to the Royal Liverpool Country Hospital for Children. Being the results of researches carried out by the author with the assistance of John Westray Cropper, M.B., M.Sc. (Liv.), M.R.C.S. (Eng.), L.R.C.P. (Lond.), Assistant to the Research Department of the Royal Southern Hospital, Liverpool. With 129 illustrations. Price, $4.50 net. Philadelphia, P. Blakiston's Son & Co., 1911.

It is extremely difficult to do justice to a work of this type. The author seems to have entered upon a very complicated and difficult field without the necessary preliminary training, and throughout the entire volume there is evidence of a lack of critical verification of the phenomena which he discusses. It is doubtful whether many persons will agree with his interpretation of the pictures of the alterations in leucocytes when acted upon by certain physical and chemical agents. Certainly it will take more careful work than is contained in this book to overthrow the studies of Heidenhain on mitotic division of leucocytes carried out some fifteen years ago. The volume does not, as its title leads us to expect, throw any light on the problem of cancer.

Old Age Deferred. The Causes of Old Age and Its Postponement by Hygienic and Therapeutic Measures. By Arnold Lorand, Carlsbad, Austria. Second Edition. Translated, with additions by the author from the third German edition. Price $2.50. Philadelphia: F. A. Davis Company, Publishers, 1911.

The common belief has been, and perhaps is yet, that a man is as old as his arteries, and that it is the degeneration of the arteries that produces what is known as senile decay or old age. However, Dr. Lorand is of a different opinion and holds that old age is a chronic disease due to degeneration of the glands with internal secretions, or ductless glands, and of the thyroid, the sexual glands, and the adrenals in particular. Furthermore, Dr. Lorand shows in his book that such degeneration is amenable to treatment in the same way as are chronic diseases in general. The volume is lengthy, containing no fewer than sixty-eight chapters, and is, in fact, a consideration of hygiene from various points of view. Possibly the most distinctive chapters are those which deal with the thyroid gland, for the author thinks that old age mainly depends on the quality of the thyroid, for the reason that the condition of the thyroid gland governs the whole circulatory system. The connection between the thyroid gland and sexual glands is pointed out and attention is drawn to the fact that, as a rule, changes in the thyroid produce certain changes in the sexual glands. The author also states that not only can old age be caused with more or less certainty by degenerative changes in the sexual organs, but by various kinds of intoxications. The consumption of alcohol specially influences the ductless glands. Small quantities may at first stimulate their action, but large quantities if taken for a very long time will cause degeneration. Having shown that the condition of the ductless glands is responsible chiefly for the causation of old age, Dr. Lorand devotes the larger portion of his book to an exposition of many means by which old age may be deferred. He does not promise the elixir of youth, but he does plainly say that by following the precepts of health laid down by him an individual may not only live, but enjoy life, to a far greater age than is usually reached in these days. He somewhat severely reprobates the mode of life led by the ordinary American business man and points to him as a glaring example of how life should not be lived. The whole work is interesting in a high degree, and if one may be inclined to doubt some of the statements with regard to the deleterious influence of the ductless glands there can be no doubt that the tenor of the book is suggestive. As for the chapters on the means for preventing old age they are excellent from the hygienic standpoint.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. By Numerous Contributors. 1911: Twenty-ninth Year. Price $3.50. New York: E. B. Treat & Company, 1911.

This volume maintains the unusually high standard that has been reached by former editions of this work. As an epitome of the latest advances in medical science, this annual for many years has been a valuable aid to the busy practitioner, and even to the one who has kept closely in touch with current literature this book has provided an admirable review and a means of connecting many scattered threads of information. An important innovation in the present volume has been the indexing of all matter referring to therapeutics under the names of diseases in the dictionary of new treatment. The dictionary of new remedies is fairly complete. There are special sections on radiology and electrotherapeutics; hormones; the diagnosis of morbid tissues, illustrated with many plates, some of which are colored; and the practice of pharmacy and the sale of medicines. The second part of the work comprises a review of medical and surgical progress for 1910. Among the noted contributors may be mentioned J. B. Deaver, who writes on abdominal surgery; E. H. Fenwick, on urinary surgery; Sir C. E. Ball, on rectal surgery; R. Hutchinson, on general medicine; Professor Hugo Sellheim, who contributes a newer method of cesarean section; P. Stewart, who writes on nervous diseases; Professor G. F. Still, on medical diseases of children; E. H. Tweedy, on pubiotomy; and R. Gundermann, on thoracic surgery. The subject of Brill's disease is discussed in a full review of and liberal quotation from Ziegel's article in the Medical Record, by E. W. Goodall, who believes that Brill's disease is really a form of typhus fever.

Die Paralysis Agitans. Eine Monographie von Dr. Kurt Mendel, Nervenarzt in Berlin. Berlin: Verlag von S. Karger, 1911.

This is a monograph of 106 pages dealing with the subject of paralysis agitans, which is studied in great detail under the following headlines: historical remarks, occurrence and etiology, prodromata, symptomatology, course and prognosis, diagnosis and differential diagnosis, complications, pathological anatomy and pathogenesis, and therapy. There is also given an extensive bibliography.

Polyzythämie und Plethora. Von Prof. Dr. H. Senator, Geheimer Medizinalrat in Berlin. 2 M. 40. Berlin: Verlag von August Hirschwald, 1911.

In this brochure of eighty pages the author discusses the various changes in the blood that have been studied chiefly during the past twenty years under the names of polycythemia, and poly-or hyperglobulia, and also in relation to the conception of plethora.

Die Psychopathischen Konstitutionen und Ihre Soziologische Bedeutung. Von Dr. Med. Helenefrederike Stelzner. Berlin: Verlag von S. Karger, 1911.

It was Professor Ziehen of Berlin who first differentiated the psychopathic constitution from the normal on the one hand and from the psychoses on the other. With the object of showing the sociologic significance of the large class of individuals who occupy the borderland between sanity and insanity the author has written this volume. It is noted that there are prisons for the criminals, asylums for the insane, houses of correction for vagabonds, and guardian homes for the unprotected young. But what, it is asked, is done for those who in addition to all the normal characteristics still have the capacity for crime, for insanity, vagabondage, idleness, and for all forms of moral delinquencies? Whence do they come, whither do they go, these citizens of the neutral country between health and disease? What values do they represent, and how are these values utilized? What harm do they cause the social body, and how can this harmful influence be met? These questions are asked by the author at the outset in setting forth the characteristics of this large class of individuals. These are studied from the viewpoint of etiology, including heredity and traumata of exogenous nature, symptomatology, prophylaxis, and treatment.

A Handbook of the Surgery of Children. By E. Kirmisson, Professor of the University of Paris; Surgeon to the Hospital for Sick Children, etc. Translated by J. Keogh Murphy, M.C. (Cantab.), F.R.C.S., Surgeon, Miller General Hospital for South East London; Senior Assistant Surgeon, Paddington Green Children's Hospital. $7.00. London: Henry Frowde, Oxford University Press; Hodder and Stoughton, 1910.

Within recent years there have appeared a number of works dealing with the surgery of childhood, a subject which has justly claimed recognition apart from the broad subject of surgery in general. The present volume is one of the latest additions to this list. It is a most noteworthy contribution to medical literature, of value not only to the pediatrist but also to the general practitioner to whom are frequently presented problems relating to the surgery of his little patients. These problems are not necessarily those of operative interference; they are largely those of prevention, and the simple medical, gymnastic, and mechanical management of a host of conditions. The author has wisely and "purposely left aside all pure theory, history, pathological anatomy, and pathogeny, in order to insist, above all, on the knowledge of those things which are essential in practice, that is to say, symptoms, diagnosis, and treatment." His aim has been "not to give a uniform description, in which everything is on the same level, but on the contrary to paint a picture in which the principal facts will be found among the high lights and in the shadows all that is of less usefulness." This is an admirable aim, as the result of which the volume is singularly free from overpadding with non-essentials. Considerable space is accorded to the two great classes of conditions that dominate infantile surgery, namely, malformations, and diseases of the locomotory apparatus. Special attention is also paid to appendicitis, mastoiditis, enlargement of the tonsils, adenoids, retropharyngeal abscess, empyema, intussusception, and prolapse and polypi of the rectum. The practical phases of infantile surgery are emphasized; the treatment of hip disease, Pott's disease, clubfoot, and congenital dislocation of the hip is presented with special regard to the needs of everyday practice. The book is divided into four parts. Part I deals with surgical affections of congenital origin. Part II comprises injuries in childhood. Part III deals with inflammatory lesions and disorders of nutrition. Part IV takes up the subject of neoplasms. The section dealing with congenital affections comprises fully one-third of the entire volume, and represents a most complete and scholarly contribution to this subject. Indeed this is one of the strongest features of the work, the description of such conditions as harelip, cleft palate, clubfoot and congenital dislocation of the hip is presented with full recognition of established methods of treatment. In Parts II and III one discerns amid the many praiseworthy features a few imperfections. The subject of burns, an elementary one, it is true, but nevertheless demanding skill and judgment, is presented rather briefly, while the treatment of fractures, while covering the essential points, is lacking in detail. Tuberculosis of the bones and joints is dealt with rather fully, nevertheless many important modern aspects of this subject are omitted. The sea-air and hygienic treatment are not even mentioned, while the treatment of tuberculous sinuses by means of the bismuth paste injections is not alluded to. The subject of scoliosis is properly accorded the large amount of space that it deserves. In the treatment of empyema by means of resection of a portion of a rib, the author's practice is at variance with the modern tendency toward simplicity in the management of this condition, namely, by simple incision or by continuous aspiration. The treatment of the various abdominal conditions, particularly intussusception, is fully covered. There is an appendix on anesthesia in children, written by Cecil Hughes, M.B. In this the modern tendency largely to discard chloroform in anesthesia on account of its dangers is not heeded; chloroform and mixtures of chloroform with ether and alcohol are advised. In these criticisms of a generally admirable book the reviewer is aware of the differences in teaching and in practice that prevail in different countries. With this qualification it may be noted that these criticisms lose some of their force. At any rate it must be acknowledged that this volume is a valuable production, reflecting the results of wide experience and seasoned scholarship.

Three Contributions to the Sexual Theory. By Professor Sigmund Freud, LL.D., Vienna. Authorized Translation by A. A. Brill, Ph.B., M.D., Clinical Assistant, Department of Psychiatry and Neurology, Columbia University; Assistant in Mental Diseases, Bellevue Hospital; Assistant Visiting Physician, Hospital for Nervous Diseases. With Introduction by James J. Putnam, M.D. $2.00. New York: The Journal of Nervous and Mental Disease Publishing Company, 1910.

There will undoubtedly be a large number of readers of this first English translation of Freud's famous "Three Essays," which represent an excursion into one of the latest developments of psychopathology. The first of these essays is entitled "The Sexual Aberrations." In this one of the main thoughts conveyed is the original predisposition to bisexuality, which in the course of development has changed to monosexuality, leaving slight remnants of the stunted sex; and the disposition to perversions is the primitive and universal disposition of the human sexual impulse, from which the normal sexual behavior develops in consequence of organic changes in the course of maturity. The second essay deals with "The Infantile Sexuality." The thesis is that the child brings along into the world germs of sexual activity and that even while taking nourishment it at the same time also enjoys a sexual gratification, which it then seeks to again procure for itself through the familiar activity of "thumbsucking"! The title of the third essay is "The Transformation of Puberty." In this an attempt is made to study the serious changes produced by the appearance of puberty, during which there is a subordination of all other sources of the sexual feeling to the primacy of the genital zones. One may not entirely agree with Freud's novel conclusions, nevertheless these open up new vistas of thought. Not the least of these is, as aptly described in the words of Putnam, "that the whole progress of civilization, whether in the individual or the race, consists largely in a 'sublimation' of infantile instincts, and especially certain portions of the sexual instinct, to other ends than those which they seemed designed to serve."

Lectures on Cosmetic Treatment. A Manual for Practitioners. By Dr. Edmund Saalfeld of Berlin. Translated by J. F. Halls Dally, M.A., M.D., B.C. Cantab., M.R.C.P. Lond. Physician to the St. Marylebone General Dispensary, Welbeck Street, W.; Fellow of the Royal Society of Medicine; Assistant School Doctor and Examiner to the London County Council; Late Assistant in the Dermatological Departments of St. Bartholomew's and the West London Hospitals. With an Introduction and Notes by P. S. Abraham, M.A., M.D., B.Sc., F.R.C.S.I., Surgeon for, and Lecturer on, Diseases of the Skin, West London Hospital and College, Late Surgeon to the Skin Hospital, Blackfriars. New York: Paul B. Hoeber, 1910.

It is a relief to find in the author's preface no sign of apology for writing a book on cosmetic treatment. The antiquated idea that this subject is unworthy the physician's study is, fortunately for mankind, fast taking its place among traditions. The writer of this valuable but concise treatise has for years given his undivided attention to this specialized branch of dermatology. The rapid sale with which the first edition has been met is proof of the need of just such a scientific book on this subject. This last edition includes the latest work in the domain of cosmetic science. Original drawings of microscopical preparations replace five of the illustrations that appeared in the first edition. The volume is a worthy addition to the library of both dermatologist and general practitioner.

Society Reports.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Meeting Held March 20, 1911.

The President, Dr. Reynold Webb Wilcox, in the Chair.

An Adjustable Footbrace for Patients Sitting Up in Bed.—Dr. A. Ernest Gallant presented this appliance. He said that at the last meeting of the association in the discussion on "Posture in Certain Medical Conditions," it was quite evident that the comfortable maintenance of patients in the semi-reclining, Fowler, or sitting posture while in bed was attended with considerable difficulty, and had taxed many ingenious minds in devising means for overcoming the tendency to slide down toward the foot of the bed with which all were familiar. Having had during the past year a bedridden patient under his care, it occurred to him to have made the footbrace now presented, and the result had been very gratifying. It is constructed of wood. A board 16 inches long is fastened to a hollow square at a slightly oblique angle; another board of the same length is fastened to a solid square; the hollow square is inserted into the solid square, and holes are drilled through at 1 or 2-inch intervals for the insertion of wooden pins, by means of which the position of the footboard can be extended or shortened. The footboard is padded, or a pillow may be placed for the feet to rest against. Dr. Gallant has found that the muscular effort brought into play by this device goes far toward maintaining the tone and strength of the muscles of the legs and thighs; so that the weakness of the legs so distressing to patients on getting up after long confinement in bed is prevented. By varying the extension of the footrest from day to day the pressure point on the buttocks can be changed and bed sores avoided. A small pillow placed under the knees will obviate wearisome strain on the hamstring muscles and still further lessen the discomforts of sitting up in bed.

How May We Make Our Scientific Nomenclature More Accurate?—Dr. Achilles Rose made an urgent plea for the correct, as well as general, use of Greek in scientific nomenclature. He began by saying that with the new relations now existing among the civilized nations of the earth there had come to be felt the necessity of one common language. It might be stated, however, that scientific nomenclature was independent of the language of commerce and everyday communication, and whatever success might attend the Esperanto movement, for instance, this did not aim to affect scientific names, especially those of medical science. But there were some men of science who were opposed to an international language of science and opposed to the establishment of a uniform scientific nomenclature, in place of the imperfect, incorrect one now in use. It was necessary, therefore, that the opposition which had been met with should be overcome, and that we should return to the ancient source of our science as regards scientific language. This was a cause worthy of our best efforts, and the fact should be known by all that Greek was not a dead language, but, on the contrary, one which to-day was spoken by several millions of people. Moreover, Greek was cultivated by many scholars outside of Greece, and from this language numerous scientific and technical terms were continually being coined. Having spoken of his own labors in behalf of reform in our nomenclature, Dr. Rose referred at some length to the great historical Greek lexicon now in course of preparation, and went on to say that for physicians a work of this kind meant a considerable gain, because by its aid the correct scientific denomination of words of Greek origin could be definitely established. At the conclusion of the paper Dr. Rose stated that he had received from eminent men in the professional world numerous letters of approval and encouragement in his work, and two of these he read. One was from Dr. Eschle, director of the State Hospital Sinsheim, at Heidelberg, and the other from Dr. Zimmerer, Professor of Philology at Regensburg.

The president, Dr. Wilcox, said he was sure we all desired a more scientific and harmonious nomenclature.

Dr. Gallant offered the following resolutions, which were unanimously adopted: *Whereas*, We, the Medical Association of the Greater City of New York, realize the woeful lack of etymological uniformity and exactness in medical nomenclature, and deplore the use in it of so many hybrid terms; and, further, recognizing the importance of adopting and adhering to the highest standard; therefore be it *Resolved*, That we hereby tender to Professor Achilles Rose our heartiest congratulations on his work in the past; that we highly appreciate his uplifting paper of this evening; that we assure him of our cordial cooperation in the future, and express the hope that he may live to see the dawn of a "renaissance" in American medical nomenclature, when pure, classical Greek will be the standard in scientific medicine.

The Chemical Relationship Between Diabetes, Gout and Cystinuria.—Dr. William H. Porter said that it must be recognized by all that these three conditions differed from each other chemically, or were related to each other by virtue of the fact that they belonged to that great class of diseases known as disturbances in metabolism. They were essentially diseases in which there was an imperfect oxidation reduction of the proteid molecule. To understand these conditions perfectly we must have an accurate conception of what occurred when metabolism was normally effected and what the normal end products were. When oxidation and metabolism were perfectly performed, the normal end products were a certain amount of urea, uric acid, kreatinin, sulphuric acid in the form of an ethereal or fixed sulphate, carbon dioxide, and water; all of which escaped from the body through the kidneys. In addition to this, we had eliminated through the liver taurocholic and glycocholic acids, biliverdin and bilirubin carbon dioxide, and water. Another important point to remember, in connection with the oxidation and elimination of the nitrogen of the proteid, was that, in round numbers, only 73 per cent. of the nitrogen left the body through the kidneys, and that the other 27 per cent. left the body through the liver and the alimentary canal. This was a fact not as well recognized as it should be, and owing to this much error had crept into the elucidation of these disturbances in metabolism. It was Dr. Porter's belief that normally uric acid was produced only by the oxidation reduction of the proteid molecule in the epithelial cells of the kidneys; that it never occurred in the blood. It was a substance that was wanted only in the lumen of the uriniferous tubules to convert the neutral phosphate of soda into the acid phosphate, thus rendering the urine acid and holding the earth phosphates in solution. The union of the acid with the phosphate naturally produced a urate, so that normally the urine, as voided from the bladder, did not contain any free uric acid. Gout was a condition in which there was an overproduction of uric acid. Now, simple overproduction of uric acid did not constitute the phenomenon which was recognized clinically as gout, for we often saw cases in which there was an enormous overproduction of uric acid and yet with no gouty symptoms. In addition to the overproduction of the uric acid we must have an abnormal nutritive condition of the various protoplasmic structures of the body—more frequently seen in connection with the cartilage cells of the joints. When this occurred the proteid molecule was drawn into the protoplasm of the cartilage cell with oxygen and vicariously oxidized in the cartilage cell. This

resulted in the formation of uric acid in the cells of the cartilage of the joints and we then had the condition which chemically might be called gout. The uric acid immediately set up active chemical action and there were developed urates and insoluble calcium phosphates, while a permanent deposit was formed. This marked chemical activity naturally produced a great deal of pain, exciting, as it did, a true inflammatory process to wall in the foreign body which resulted from such chemical activity. Thus we had the explanation for the gouty attack and its symptoms. Drop the oxidation reduction of the proteid molecule to a slightly lower degree, and we had not only a decrease in the urea and overproduction of uric acid, but there resulted glucose as one of the end products of the proteid suboxidation. The glucose did not come from the imperfect transmutation of the starch, sugar, or fats, but from the imperfect oxidation of the protein molecule in the renal cells, and in Dr. Porter's opinion the glucose molecule was produced only in the cells of the kidneys. To his mind there could be no question that there were two distinct types of disturbance of metabolism in which a glucose molecule was an end product of the imperfect oxidation of the protein molecule in the kidney cells. One was the result simply of eating and drinking too much, the other was associated with some intrinsic changes going on within the system. The former yielded readily to treatment, while the latter was often quite difficult to handle. In the two instances the glucose molecule, while it contained the same number of atoms, differed materially in its isomeric construction. In that condition designated cystinuria we had an imperfect oxidation reduction of the protein molecule in the renal cells in which one of the resulting end products was a sulphur-bearing molecule which was known in chemistry as amino acid. When this form of suboxidation occurred cystin crystals were found in abundance in the urine. While in themselves nonirritating they were apt to mass together and form calculi. Just what caused the various types of suboxidation had not been fully determined. It might be due to the formation of toxins in the alimentary canal or to changes within the system by which toxins were formed that deviated the oxidation reduction from the normal to the abnormal. In conclusion, he said that as he was asked to speak only on the chemical differences, or the relationship of these three conditions, he would not occupy further time in attempting to argue the pros and cons concerning these conditions.

Some of the Latter-Day Endeavors in the Treatment of Diabetes.—Dr. Heinrich Stern read this paper, which will be published later.

The Newer Treatment of Gout.—Dr. George Meyers said that gout was a metabolic disorder due, not to proteins as a class, but to one particular form of proteins, namely the nucleoproteins. The fault might be due to the ingested nucleoproteins or to those special ferments which metabolized them. The gouty deposits in the tissues were increased by sodium salts. The treatment, therefore, should consist of the following points: (1) Avoid the nucleoproteins. (2) Rest or alter the ferments. (3) Avoid sodium compounds. The first of these requisites was best brought about by the use for a few days of a diet free from nucleoproteins, and then establishing a tolerance by the gradual addition of nucleoprotein material to the diet. The ferments were rested by this avoidance of nucleoproteins. By the use of a salt-free diet the amount of ingested sodium was limited. When drugs were employed (as for the relief of pain, etc.) it was advisable to select strontium or potassium salts, instead of sodium salts. So, too, the mineral waters partaken of should be free from sodium, and in this connection it was important that great care should be taken in selecting proper health resorts to which to send patients. When he had finished the paper Dr. Meyers said it would have been noticed that nothing was said in regard to colchicum. This was because the drug had no effect whatever on the disease, its only service being in the relief of pain. Radium, however, appeared to exert some action on fermentation processes, and, therefore, such mineral springs as contained this agent in their waters might prove useful to the gouty patient.

Cystinuria.—Dr. Frederic E. Sondern said that true cystinuria was a rare condition; only 175 cases being on record three years ago, when K. von Hoffmann published his collective review of the subject. In approximately 35,000 specimens of urine Dr. Sondern had met with it in but three instances, and only one of the three patients presented symptoms referable to this condition, the presence of cystin in the urine being discovered on routine analysis. Cystinuria, as far as he was aware, did not give rise to any clinical symptoms unless it had formed calculi in the urinary tract; it would seem to be a metabolic curiosity, rather than a true clinical entity. In one of the cases he had seen there was acute gonorrhea, the second patient was to be operated on for a lipoma of the neck, and the third had his urine examined as a precaution before applying for life insurance. In all three, however, there seemed to be a distinct neurotic taint. In a case described by Dr. Horatio B. Williams in a recent article on "Protein Metabolism in Cystinuria" there was a history of syphilis, frequent gastric indigestion, and repeated attacks of muscular rheumatism. While most textbooks mentioned cystin as a variety in lithiasis, it was difficult to find the clinical history in an actual case. Thus, Israel, in his "Surgical Clinic of Kidney Diseases," though he referred to cystin calculi and the fact that this substance was found mixed with other elements in some stones, did not cite a single instance in his long list, unless those largely composed of sulphur might be so considered. Cystin was an amino acid originating as an intermediary product in protein metabolism, and when occuring in the urine was an evidence of incomplete oxillation of protein material. It was formerly believed that it results from putrefaction in the intestine, but the chief practical object of the recent publications by Loewy and Neuberg and by Wolf and Shaffer, as well as of the paper by Williams, was the attempt to prove conclusively that cystin is not a product of intestinal putrefaction. A conservative opinion, based on the published research work on the subject would be that cystinuria is the outcome of a faulty amino acid oxidation dependent upon faulty albumin catabolism. In a way it was not unlike the fault in protein metabolism found in some varieties of toxemia which had recently received much attention. In these cases gross and microscopic lesions were found in the liver, and the faults in the chemistry of the urine were apparently referable to faulty hepatic function. It seemed not improbable that the disturbed protein metabolism causing cystinuria may also rest on a similar fault in hepatic function, the cause of which is unknown. Dr. Sondern said he would not go into the details concerning the experimental feeding of cystinuries, as that would mean a review of much chemistry, without repayment in practical clinical result.

Dr. A. Austin Cossitt reported a case of cystinuria in a girl ten years old, of a neurotic family. The trouble seemed to have commenced three years ago, when she had an attack of diphtheria, and the parents were disposed to attribute it to the antitoxin then administered. The urine, which was scanty, contained blood and occasional cystin crystals, and was also of high acidity. The child suffered from marked gastrointestinal symptoms, and the stools were sometimes thin and sometimes not. She had been under the care of a number of the best physicians, but had not been benefited. Dr. Cossitt was the first, however, to discover the cystinuria.

Dr. Louis Faugères Bishop spoke of the importance of

the intelligent selection of mineral waters and "cure" resorts. There was a good deal of difference between the different cures. Every year we all saw a number of patients who went to the wrong cures and who were thus made very much worse. There was a good deal in this question of sodium and the alkalies in general. There was no doubt in his mind as to the danger from autoinfection due to intestinal putrefaction, which, in common with many others now, he believed to be the ultimate cause of arteriosclerosis, myocardial disease, and nephritis. The alkaline mineral waters were liable to do much harm, as they tended to promote such putrefaction, while an acid condition in the alimentary canal encouraged the growth of bacteria inimical to putrefaction processes. To him the most suggestive points which had been brought out this evening were the limitation of the use of sodium and the proper selection of cures. He was a great believer in Nauheim, and one of the best things about it in his opinion was that patients do not drink its waters.

Dr. Meyers, in closing, said that to any thinking man it must be apparent that the benefit derived from the foreign spas was not from the drinking of the waters, but from the change of environment, diet, and general mode of living. He could fully corroborate what Dr. Bishop had said, for it was certainly true that the patients at Nauheim who got along the best were those who did not drink the water. Baden Baden was a very good resort because its springs supplied pure water with a very small content of salts, and many of our American waters were also of this character.

Dr. Sondern said he did not know how long cystinuria was likely to persist. From what he had read the different men who had had experience with cystinuria had never noted its disappearance except in one instance. In that it never returned again.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held January 26, 1911.

Dr. H. D. Furniss in the Chair.

A Case of Cystocele After Hysterectomy, Cured by Colpectomy.—Dr. A. E. Gallant presented this patient. The uterus was removed in 1897. On February 8, 1900, when she was fifty-four years old, she presented herself because of being very much annoyed by a bulging bladder. She was the mother of nine children, the last eighteen years ago. She complained of backaches, distress before and after micturition, and the frequent passing of small quantities or urine. The operation performed was panhysterocolpectomy. She was out of bed on the eighth day and had been well ever since.

Large Fibroid Growth in a Woman After the Menopause.—Dr. Hiram N. Vineberg reported this case. He said that inasmuch as the idea seemed to be prevalent among the profession that fibroids, as a rule, seemed to give trouble at the menopause, he wished to report this case. The patient was fifty-three years old and had been under treatment for over nine years because of repeated hemorrhages and pressure symptoms. During the past two or three years, however, the hemorrhages had ceased with the onset of menopause. She had pressure symptoms, indigestion, pain, etc., and when she presented herself she had a tumor which extended above the umbilicus. She had never given birth to children. Operation was performed and she made a good recovery. The growth removed was larger than an adult head.

A Case of Hydatiform Mole with Chorioepithelioma.—Dr. Vineberg presented this specimen because of its unusual interest and gravity. The patient was a young married woman, a German, nineteen years old. Three months ago she complained of a great deal of pain in her abdomen. She was very pale and pasty looking. Upon examination he found a pregnant uterus reaching to the umbilicus, and two cystic masses situated behind the uterus. There were much albumin and many casts in the urine. He advised the immediate emptying of the uterus as well as the removal of the ovarian cyst at the same time or later. At operation he found she had a hydatiform mole. Observing that she had double cystic ovaries, he did a hysterectomy. The microscopical examination revealed the presence of hydatiform with chorioepithelioma fairly advanced. She made a good recovery from the operation. Promptly after the operation the patient had a distinct eclamptic seizure, a rare occurrence in cases of hydatiform moles. Findley had collected 210 cases and in none did eclampsia occur. This was the fourth case of chorioepithelioma that Dr. Vineberg had seen within three years. The albumin soon disappeared from the urine. Recently she had had small hemorrhages from the vaginal vault and this looked like a recurrence. The pathologist said he could find only connective tissue cells in the growth which was removed and no evidence of chorioepithelioma. There were no metastatic growths in the lungs or elsewhere. It was fortunate in this case that the patient presented double ovarian cysts; otherwise he would have been reluctant to remove the uterus, and he probably would not have known of the presence of the malignant chorioepithelioma until some time after, when metastatic growths would have developed in the lungs or other organs.

Panhysterocolpectomy.—Dr. A. E. Gallant read this paper. He said that before an audience of specialists it was unnecessary to recapitulate the many methods and means employed for the relief of that condition which, though not so frequent as in years gone by, yet, nevertheless, had come to his notice in three instances in one clinic. That the greater number of cases could be cured or relieved by one of the many plastic denudation or suspension methods was admitted by all, but there were a number of recurrences after such operations. This fact had led Dr. Edebohls to devise a new operation for prolapse which he named "Panhysterocolpectomy" (Medical Record, Oct. 12, 1901). Since Dr. Edebohls' first report the only references they had been able to find to this operation were in a paper by Dr. Waldo, who reported three cases, and two cases which Dr. Boldt referred to, which fulfilled all the claims of the originator in favor of the operation. Dr. Edebohls stated that he had operated eight times. All thirteen cases were remarkable because of the absence of shock and the rapid and smooth convalescence. It was not until July, 1910, that a case came under the observation of the writer which presented the necessary conditions for so radical an operation. This patient was sixty-eight years of age and had ceased menstruating fourteen years ago. She was suffering from a well marked prolapse of the bladder and protrusion of a long ulcerating cervix, which it was feared might be of a malignant type. She had also an old second degree laceration of the perineum. Her father had died of cancer of the shoulder, and her mother, uncles, and cousins of tuberculosis. The technique of the operation was as follows: First step: a transverse incision was made just inside the hymen posteriorly, and a longitudinal incision from the cervix to the fourchette; blunt and knife dissection of left posterior section of the mucous membrane was done; this was repeated on the right side. Second step: a circular incision was made just inside the vagina in front; dissection was done from the right to the center and from the left to the center, leaving the flaps attached to the cervical junction. Third step: the bladder was freed from the cervix; the anterior pouch was opened and the peritoneal cavity was entered. Next the posterior cul-

de-sac was perforated; the broad ligament was clamped and the uterus cut free. The broad ligament stumps were sutured individually and then drawn together and sutured. Fourth step: this consisted in the insertion of three catgut, purse-string sutures, one after the other, taking great pains to push the preceding suture well upward before tying the next one below. A fourth suture just within the vestibule was tied down on a cigarette drain and this completed the operation. The convalescence was afebrile: the patient was out of bed on the seventh day and on the porch the day following. Denudation of the vagina did not interfere with its contractility, but rather seemed to excite it. The denudation could be markedly facilitated by first making a circular incision through the mucous membrane at the vulvovestibular junction and by making four long incisions from the hymen to the cervix, quadrisecting the exposed vaginal membrane and proceeding with the denudation of one strip after another, being careful to work in the loose cellular planes beneath the mucous membrane, downward and outward, leaving the flaps attached to the cervix. Panhysterocolpectomy was indicated in women suffering from cystocele, with or without prolapse of the uterus or rectum, who were incapable of impregnation, who had passed the child-bearing period, and whose husbands were willing to forego marital relations, and in those in whom other operative measures had completely failed. Complete excision of the uterus and vagina with columnization of the vaginal walls was a safe and sane operation and would insure an absolutely permanent cure with the minimum of danger and with the maximum of safety from recurrence.

Dr. Herman J. Boldt said that if there was a complete prolapse of the uterus and vagina there was only one operation, the one described, in which they could expect to obtain a permanent cure. He had performed it five times. So far as the technique was concerned, the one described by the late Dr. Edebohls was, in his opinion, the best. There were practically no difficulties in the operation. If drainage was used, it was contrary to the advice of Dr. Edebohls; with a clean surface there was no call for drainage. In two of his cases some temperature followed the operation. But this soon subsided and he had no further trouble. With regard to the indication for this operation, panhysterocolpectomy for prolapsus vaginam, it should be borne in mind that there must be a *complete* procidentia.

Dr. Wesley G. Vincent said that he had assisted Dr. Edebohls for many years, practically up to the time of his death. He quoted from Dr. Edebohls' paper on "Panhysterocolpectomy: A New Prolapsus Operation" (Medical Record, October 12, 1901), as follows: "The operation is indicated whenever the certain and permanent cure of a prolapsus of the uterus and vagina, either primarily or after the failure of previous operation or operations, forms the one paramount desideratum, other considerations in comparison being relegated to the background. The limitations of its applicability and the contraindications arise from the necessity or desirability, in any given case, of perpetuating the functions of the uterus or vagina In women past the child-bearing age the uterus need, of course, not be considered. It is quite a different matter, however, with the vagina, and the impossibility of further sexual relations must be clearly presented to the patient, and fully understood and accepted by her, prior to deciding upon the operation. If the patient be a widow past the menopause, the decision will rest entirely with her; if a married woman, her husband must be consulted as well." Since Dr. Edebohls' death, Dr. Vincent had had one case.

Dr. Howard Canning Taylor believed the operation described to be a very satisfactory one: at the same time it would be a mistake to operate upon a woman of advanced age, even though she was willing to submit to it. A woman well along in years was a particularly bad subject for any plastic operation and so the operation, panhysterocolpectomy, was the better. When there was a complete prolapse, the removal of the uterus and vagina was not very difficult. Patients who were sixty-five or seventy years of age were not good subjects for any plastic operation. Personally he preferred to do the operation described by Dr. Gallant.

Chorioepithelioma, with Report of Three Cases.—Dr. Michael Caturani read this paper. He reviewed the literature on the subject and said that until Sanger in his paper before the Leipzic Obstetrical Society first described a tumor differing absolutely from any known tumor, and emphasized its peculiar relation to pregnancy, the nature of this growth was not clearly understood, but since that time the number of cases reported had increased and at present the literature contained about 300. The obscure etiology and the strange diversity in clinical evolution of the various cases rendered it desirable to increase their statistics. According to the numerous pathological interpretations, different names had been assigned to the tumor, but all of the opinions advanced could be reduced to the following: (1) Maternal origin; a tumor of connective tissue nature (Sanger, Pfeiffer, Veit); (2) fetal origin: a tumor of an epithelial nature (Aschoff, Marchand, Teacher); (3) intermediate: mixed epithelial, the cells of Langhans being of fetal origin and the syncytial cells of maternal. This was the first theory of Marchand, Frankel, Williams, etc. The author outlined the work by which the fetal origin of the tumor had been demonstrated. The etiology of the tumor was the most important question for study, since from a practical standpoint it might offer important suggestions in prophylaxis and treatment. Pregnancy seemed to be an essential factor, although several cases had been reported that might offer exceptions. One case was mentioned by Bland in which the woman was 58 years old and past the menopause. Similar cases had been reported by Teacher, and the author had had a case in a woman 51 years of age, where the tumor developed five years after the passage of a hydatidiform mole, and more than four years after the menopause. Most tumors occurred between the ages of 22 and 32, the most prolific period. The relative frequency varied in the following way: After expulsion of a mole, after abortion, before or after a normal delivery, following ectopic pregnancy. The many theories in regard to the cause of these tumors, from the microbic to the cellular and chemicocellular that had been advanced, were reviewed, but after all the writer said they had no knowledge of the exact cause of chorioepithelioma. The time elapsing between labor, abortion or the expulsion of a mole and the clinical manifestations of chorioepithelioma was variable. In Ladinsky's statistics the average time was eight weeks after molar pregnancy, seven weeks after abortion, and five weeks after labor at term. Successive statistics showed a greater variability in the period of incubation. Cases not treated surgically usually ended in death in from a few weeks to a few months. Metastases through the blood vessels appeared at an early stage, and their presence was considered one of the chief characteristics of the disease. The lungs appeared to be most frequently affected, next the vagina, which in many cases was the primary site of the disease. The presence of small, extremely vascular tumors in the vagina was almost pathognomonic. Chorioepitheliomatous masses were extremely friable, fungous and arborescent and it was easy to remove pieces of spongy brown tissue for microscopical examination. The usual site of the growth was on the fundus and the posterior wall. The history of a previous pregnancy, the age of the patient, the consistency of the os made it easy to exclude cancer although the age and the menopause were apt to suggest cancer of the body. While he admitted that it was neces-

sary to use extreme care in the use of the curette, he said it was essential to get deep curettings in order to enable the pathologist to make a positive diagnosis. In doing a curettage, he recommended successive painting of the interior of the uterus with formaldehyde, the action of which was to fix cellular elements and to check their migration. Chorioepithelioma was justly considered one of the most malignant of tumors. It should be their aim to prevent their occurrence by careful curettage following the discharge of a mole, by curettage after abortion as a routine measure, and by taking care that all placental remains should be removed after confinement. Once a diagnosis of chorioepithelioma was made, complete removal of the uterus and adnexa was indicated, unless the condition of the patient absolutely forbade an operation. Metastases in the lungs or other organs were not contraindications to the operation, since removal of the parent tumor was often followed by disappearance of the metastases. When the vagina was the seat of the growth it seemed advisable to the writer to remove the uterus and adnexa as there was always the possibility of chorioepitheliomatous nodes being buried in the muscularis of the uterus.

The first case reported was that of an Italian woman, 51 years of age, who had had nine children and three miscarriages. There was no history of any infection. Five years before her present illness she had expelled a hydatidiform mole, and a month later had profuse hemorrhage. The menopause followed. Two months later she began to cough and to expectorate blood. Suspecting carcinoma of the uterus curettings were sent to the pathologist who reported the presence of deciduoma malignum, also known as syncytioma malignum. The general condition of the patient prevented a radical operation. She was extremely emaciated and had a metastasis in the right lung the size of a silver dollar. The patient died three months later.

The second case reported was that of an Italian woman, 26 years of age, who had had three children. The writer first saw her 22 days after confinement when a vaginal examination revealed a small tumor, the size of an almond, on the anterior vaginal wall, about an inch from the introitus. The uterus was large, soft, and discharged a serobloody fluid. The tumor was removed and the uterus curetted. The pathologist reported chorioepithelioma and advised an hysterectomy. This operation was performed and the patient made a good recovery. Three months later she had an attack of nephritic colic and a soft tumor was found in the region of the left ureter. A month later she had a similar attack. The urine showed the presence of blood and a recurrence of the disease was suspected. The patient died a few months later.

The third case was an Italian woman, 30 years of age, who had had two children. Six months after the last birth she passed a hydatidiform mole and began to bleed profusely and irregularly. In the course of a few months she was curetted three times. The last time the curettings were sent to the pathologist who was not sure of malignancy. When she came under the writer's care he again curetted her deeply and felt positive that he had to deal with a malignant condition. The pathologist confirmed his suspicions. He removed the uterus with adnexa and the patient recovered. This was two years ago and the patient was still in good condition.

Dr. Caturani concluded as follows: 1. There was a relative frequency of this disease among the poorer classes who were less apt to seriously regard predisposing causes, such as abortions and the passing of moles. 2. For the same reason these cases were more common than the statistics would lead one to suppose. 3. When pathological examination was doubtful, one should be guided by clinical course and history as to operative intervention. 4. The character of malignancy was greater after labor. 5. Prophylaxis was of great importance and they should curette all cases after expulsion of moles, as the cells imbedded in the tissues (as in his first case) developed malignancy after five years, and in his last case a thorough and early curettage might have prevented the development of malignancy when its slow development was considered.

Dr. Herman J. Boldt said physicians now realized that chorioepitheliomata were by no means malignant; in a number of instances in which a diagnosis of chorioepithelioma was made, patients had been cured; however, in the worse class of cases a fatal result was apt to follow. In such instances as were reported by Dr. Vineberg the only way they could expect a cure was by the removal of the disease early; a radical operation should be done if a cure was to be effected.

Dr. Hiram N. Vineberg did not think that in every case of hydatidiform mole the uterus should be removed; in a previous case reported, the uterus was emptied and the patient had been well ever since. When it was decided to empty the uterus, the wisest thing to do, in his opinion, was a partial section, emptying the uterus with the hand. If there was any doubt regarding the case, or if the surface was rough and gave suspicions of malignancy, the patient should be watched with care. After three or four weeks, if hemorrhages occurred, without even waiting for the report from the pathologist regarding his findings, the uterus should be removed. Very often the report of such an examination was misleading since it was not at all easy to make a diagnosis of chorioepithelioma. Dr. Vineberg said he took a more hopeful view than Dr. Boldt and believed that in these cases the outcome was rather good. In the cases referred to there was no doubt regarding the nature of the growth, and both women were still living.

Pathological Society of Philadelphia.

At a stated meeting held March 9 Dr. J. Earle Ash presented a specimen of "Cerebral Hemorrhage from Ruptured Aneurysm of the Internal Carotid." The specimen was obtained from a woman, 67 years old, who had suffered from a chronic form of depressive insanity. She was found dead lying on the left side of her body. The aneurism of the carotid artery was situated on the same side, and it had ruptured, the blood finding its way beneath the arachnoid to the Sylvian and Rolandic fissures, along the base to the floor of the fourth ventricle, through the iter to the third ventricle and through the foramen of Monro into the left lateral ventricle. Often the internal carotid artery is found calcareous and atheromatous at its point of entrance into the cranial cavity when other vessels appear little if at all affected. Dr. C. C. Norris presented a specimen of "Torsion of the Fallopian Tube," obtained from a woman who presented pain in the right iliac fossa, together with other symptoms of appendicitis. Operation disclosed the condition named, the twist of the tube taking place close to the ovary and involving also this structure. Dr. George W. Norris presented a communication entitled "Studies in Cardiac Pathology," with lantern demonstration. He displayed on the screen a variety of lesions of the heart representing photographs of specimens studied in various musea of the city. Drs. D. Rivas and A. Garcia presented a communication entitled "Further Studies on Indol in Bouillon Cultures of Bacillus Coli," and they described a method by which the differentiation of this bacillus from the typhoid bacillus could be made in a relatively short time by means of the indol test. Drs. I. H. Aust and O. H. Perry Pepper presented a communication entitled "A Study of Case-Histories and Autopsy Protocols, with Special Reference to the Renal Findings." They found numerous discrepancies between the two sets of results, and these were attributed in part to errors of omission and in part to errors of commission.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, SOUTH DAKOTA.

Aberdeen, January 11 and 12, 1911.

ANATOMY, HISTOLOGY, AND EMBRYOLOGY.

1. Give a histological description of a hepatic lobule.
2. What is the embryonic origin of (*a*) the kidney, (*b*) the lungs, (*c*) the eyeball.
3. Describe the pancreas.
4. Give histological description of a pulmonic alveolus.
5. What displacement occurs in a fracture of the femur at the junction of the middle and lower thirds? Why?
6. Describe the ankle joint.
7. Describe the diaphragm.
8. Describe the small intestine.
9. Name the muscles of respiration. Give origin and insertion of any two.
10. Name the abdominal viscera that are (*a*) completely, (*b*) partly, (*c*) without peritoneal investment.

PHYSIOLOGY.

1. What action has the gastric juice on the carbohydrates and fats?
2. Give the composition, reaction, and uses of blood.
3. Describe the red blood corpuscles and give their best known and most important function.
4. Describe the fetal circulation.
5. Name the erectile tissues of the body and explain their function.
6. What digestive changes take place (*a*) in the small intestines? (*b*) in the large intestines?
7. Describe the sphygmograph and state its use.
8. How do arteries, veins, and capillaries differ as to function and structure?
9. Define emulsification and saponification and give examples of each.
10. What is an (*a*) efferent nerve? (*b*) afferent nerve? Give illustrations of each.

CHEMISTRY.

1. Give a test for sugar in urine.
2. Give a common name for the following formula: H_2O_2, $CHCl_3$, CH_4O, C_2H_5OH.
3. In what different compounds is sulphur found in nature?
4. What decompositions occur in the preparation of chlorine from rocksalt?
5. Give chemical name and formula for lunar caustic.

BACTERIOLOGY.

1. What kind of bacteria are most commonly found in suppurative processes? (*b*) Describe them.
phoid bacillus group?
2. What are the three subdivisions of the colon ty-
3. What do you understand by (*a*) phagocytes? (*b*) blastomycetes? (*c*) thermal death point? (*d*) antiseptics? (*e*) disinfectants?
4. Describe a diphtheritic throat. How would you obtain a culture?
5. How would you dispose of the excreta of (*a*) typhoid patient? (*b*) tubercular patient?

PATHOLOGY.

1. What are lymphocytes? poikilocytes? blood plates?
2. Give the blood changes in myelogenous leukemia.
3. What conditions are induced by (*a*) atrophy and (*b*) hypertrophy of the thyroid?
4. Give the pathology of cancrum oris.
5. Differentiate septic intoxication and bacteremia.
6. What are local infections?
7. Describe the intestinal lesion of typhoid.
8. What is an antitoxin?
9. The pathology of psoas abscess.
10. Define immunity.

THERAPEUTICS AND PRACTICE.

1. Describe three of most common intestinal worms and give treatment for one kind.
2. Describe and treat rickets. What is marasmus and scorbutus?
3. What are the contraindications of veratum viride? What is its therapeutic value?
4. How would you distinguish between autotoxemia and acute ptomaine poisoning?
5. Describe symptomatic difference between tetanus and strychnine poisoning.
6. Differentiate acute alcoholism, apoplexy, and epilepsy.
7. What is arthritis deformans? Give diagnosis and prognosis.
8. Describe and treat hemicrania.
9. What are the differences in the physical signs of mitral incompetency and functional systolic murmurs?
10. Define briefly: Aphasia, apoplexy, thermic fever, myalgia, fever, parotitis, septicemia, pyemia, pachymeningitis.

OBSTETRICS.

1. How would you treat vomiting of pregnancy? Give etiology.
2. Tell what you know about toxemia of pregnancy.
3. Diagnose and treat a case of placenta prævia, being called after mother is in labor.
4. Make an accurate diagnosis of a vertex presentation.
5. Give three main rules for the treatment of uterine inertia in labor.
6. Give immediate diagnosis and treatment of lacerations of perineum after labor.
7. How and when would you be justified in inducing labor?
8. Describe the application of forceps.
9. What is a cystic mole? Give cause for its formation.
10. When would you use chloroform in labor?

DISEASES OF WOMEN.

1. Give causes and treatment of pruritis vulvæ.
2. Differentiate appendicitis and ovaritis.
3. Etiology, diagnosis, and treatment of pyosalpinx.
4. What are the indications for hysterectomy? Describe one operation.
5. Give in detail your treatment for complete rupture of the perineal body with accompanying rectocele and procidentia uteri, in a woman past the menopause.

SURGERY.

1. Give diagnosis and treatment of strangulated inguinal hernia.
2. Diagnose and give treatment for cholelithiasis.
3. Diagnose and treat simple fracture of clavicle.
4. Diagnose and treat fracture of femur at the junction of upper and middle thirds.
5. How would you manage case of fecal fistula following appendiceal abscess?
6. Give diagnosis and treatment of hemorrhoids.
7. Given severe crushing injury for leg with shock—give treatment in detail.
8. Give diagnosis of and treatment for postoperative ileus.
9. Give diagnosis and treatment of carbuncle.
10. Give diagnosis and treatment of acute suppurative appendicitis; in case you operate, what incision would you make and why?

EYE, EAR, NOSE, AND THROAT.

1. (*a*) Diagnose and treat case of iritis. (*b*) Diagnose and treat case of keratitis.
2. Name and describe four errors of refraction and treat each. If lens is prescribed, be definite.
3. Give treatment and prognosis of severe burn of eye involving lid and ocular conjunctiva.
4. Give treatment in well marked case of hypopyon.
5. Differentiate between diphtheria and follicular tonsillitis and treat case of follicular tonsillitis.
6. Diagnose and treat a case of hypertrophy of pharyngeal tonsil.
7. Describe the Eustachian tube, giving anatomy and function.
8. Draw diagram illustrating cross-section of nose, showing turbinal bodies, and treat a case of hypertrophy of inferior turbinate.
9. Give etiology, symptoms, and treatment of empyema of frontal sinus.
10. Give three common causes of deafness and treat a given case.

SKIN AND GENITOURINARY.

1. Give symptoms, diagnosis, and treatment of a beginning erysipelas of the scalp in an infant one year old.
2. Diagnosis and treatment of erythema multiforme.
3. Diagnosis and treatment of lupus vulgaris.
4. Diagnosis and treatment of perniones.
5. Etiology, diagnosis, and treatment of acne vulgaris.

MEDICAL JURISPRUDENCE.

1. Give signs of death by drowning.
2. What are the duties of a coroner upon receiving

notice that a dead person has been found in his jurisdiction?

2. State the method of procedure, in this State, to procure the commitment of a person to the hospital for the insane.

4. In making a microscopic examination of bloodstains, what characteristics would lead you to believe they were produced by human blood?

5. What conditions, from a legal standpoint, would justify the induction of premature delivery?

HYGIENE AND SANITARY SCIENCE.

1. Give in detail the method you would use as health officer in controlling diphtheria epidemic.

2. Is infantile paralysis infectious? If so give rules for protecting the community.

3. Give incubation period of (*a*) scarlet fever; (*b*) diphtheria; (*c*) variola; (*d*) measles.

4. Give hygiene and general care of the patient to prevent infection of attendants and others in close contact with patient suffering from pulmonary tuberculosis.

5. Give general directions for the care of public schools, and care and inspection of school children.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, SOUTH DAKOTA.

Aberdeen, January 11 and 12, 1911.

ANATOMY, HISTOLOGY AND EMBRYOLOGY.

1. A lobule of the liver is about 1-20 to 1-12 inch in diameter. It has a darkish red center and a lighter circumference. The center is occupied by an intralobular vein which collects the blood from the capillaries of the lobule and flows into the sublobular vein, which latter opens into the hepatic vein. Around the lobules are the interlobular veins; these are branches of the portal system; capillaries passing from the circumference to the center of the lobule connect the interlobular and intralobular veins. Between the network of capillaries in the lobule the hepatic cells are packed.

2. The kidney is derived from the mesoderm; the lungs, from the entoderm; the eyeball, from the ectoderm,

3. See Cunningham's "Anatomy" (1909), page 1124; or Gray's "Anatomy" (1908), page 1355.

4. See Cunningham's "Anatomy" (1909), page 991; or Gray's "Anatomy" (1908), page 1404.

5. In fracture of the femur, at the junction of the backward by the gastrocnemius and plantaris. The upper fragment is drawn inward by the pectineus and adductors, and forward by the psoas and iliacus.

6. See Cunningham's "Anatomy" (1909), page 306; or Gray's "Anatomy" (1908), page 349.

7. The *diaphragm* is a musculofibrous septum which divides the thoracic from the abdominal cavity; it is fan-shaped; the broad, elliptical portion is horizontal, and the crura are vertical. It is attached to the ensiform, to the internal surfaces of the lower six costal cartilages, to bodies and intervertebral substances of first, second, and third lumbar vertebræ. Its *openings* are: (1) The aortic, transmitting the aorta, vena azygos major, and the thoracic duct; (2) the esophageal, transmitting the esophagus, pneumogastric nerves, and some small esophageal arteries; (3) the opening for the vena cava, transmitting the inferior vena cava, and small branches of the right phrenic nerve; (4) the right crural, transmitting the right splanchnic nerves; (5) the left crural, transmitting the left splanchnic nerves and the vena azygos minor. *Nerve supply:* The phrenics, lower intercostals, and the phrenic plexus of the sympathetic.

8. See Cunningham's "Anatomy" (1909), page 1064; or Gray's "Anatomy" (1908), page 1290.

9. See Cunningham's "Anatomy" (1909), page 415; or Gray's "Anatomy" (1908), pages 434 and 427.

10. (*a*) *Wholly covered with peritoneum:* Stomach, first part of duodenum, jejunum, ileum, cecum, tranverse colon, sigmoid flexure, first part of rectum, liver.

(*b*) *Partially covered with peritoneum:* Second and third part of duodenum, ascending and descending colon, middle part of rectum, bladder.

(*c*) *Without peritoneal investment:* Pancreas and kidneys.

PHYSIOLOGY.

1. The gastric juice has no effect on carbohydrates; and practically none on fats, beyond digesting the capsule of some fat cells and so setting free the fat.

2. CHEMICAL COMPOSITION OF THE BLOOD. *Plasma:* Water and solids; the latter containing proteids, extractives, fats, middle and lower thirds: The lower fragment is tilted and salts of sodium, potassium, and calcium. *Corpuscles:* Water and solids; the latter containing hemoglobin, globulin, lecithin, cholesterin, iron, and salts of sodium, potassium, magnesium, and calcium.

REACTION is alkaline.

USES: To distribute nourishment, oxygen, and the internal secretions to the tissues of the body; to remove carbon dioxide and other waste matters from the tissues so that they may be excreted by the lungs, kidneys, and skin; to regulate the body temperature. In addition, the *white corpuscles* serve as a protection to the body from the incursions of pathogenic microorganisms; they take some part in the process of the coagulation of the blood; they aid in the absorption of fats and peptones from the intestine, and they help to maintain the proper proteid content of the blood plasma.

3. The *red blood corpuscles* are biconcave discs, about 1-3200 of an inch in diameter; they are nonnucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellow. They contain hemoglobin. Their *function* is to carry oxygen from the lungs to the tissues.

4. See Gray's "Anatomy" (1908), page 583; or Williams' "Obstetrics" (1909), page 154; or Hirst's "Obstetrics" (1909), page 88.

5. The *erectile tissues of the body* are: The corpora cavernosa and corpus spongiosum of the penis, the clitoris, the bulbi vestibuli, the tissue covering the turbinated bones of the nose, and the nipple.

"Erectile tissues are tissues susceptible of turgescence and increase of size, and formed of a collection of arteries and veins intermixed with nervous filaments; the veins are varicose and contained in spaces formed by trabeculæ of fibrous tissue, being prolongations from the fibrous envelope."—(Dunglison's *Medical Dictionary.*)

6. *In the small intestine:* Proteids are turned into proteoses and peptones; starches are converted into maltose; fats are broken up and emulsified or saponified. *In the large intestine* the same processes of digestion may *continue,* but nothing new (in the way of digestive activity) is started.

7. The sphygmograph is an instrument for recording the pulsations of an artery. "There are several forms. The one in most common use is the Dudgeon sphygmograph. An essential feature of this instrument is a system of compound levers which transmits the movement of the arterial wall from the foot or pad which rests upon the skin over the artery to a tracing point connected with the last lever. This system of levers multiplies the motion of the foot about fifty times. A second feature of the instrument is a recording apparatus consisting of a clockwork which turns a pair of small cylinders, between which runs a slip of blackened paper. The tracing point rests upon this paper and records there the magnified movements of the foot or pad. The sphygmograph has the great advantage that it makes a record of the variation of pressure, and when properly used may reveal many facts about the general condition of the circulatory system." (Hall's *Text-Book of Physiology.*)

8. See Cunningham's "Anatomy" (1909), page 780; or Gray's "Anatomy" (1908), page 586.

9. *Emulsification* is the breaking up of fat globules into minute particles, and their suspension in a watery fluid. Example: Milk is a natural emulsion.

Saponification is a double decomposition between a fat and an alkali in which there are formed glycerin and the metallic salt of the fatty acid. Example: The formation of glycerin and potassium stearate from stearin and potassium hydroxid.

10. An *afferent nerve* is one that conveys impulses from the periphery to the brain; as the olfactory nerve or any sensory nerve.

An *efferent nerve* is one that conveys impulses from the brain to the periphery; as the facial, or any motor nerve.

CHEMISTRY.

1. *Test for Sugar:* Render the urine strongly alkaline by addition of Na_2CO_3. Divide about 6 c.c. of the alkaline liquid into two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth, to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color. (From Witthaus' *Essentials of Chemistry.*)

2. H_2O_2 is hydrogen peroxide; $CHCl_3$ is chloroform; CH_4O is wood alcohol; C_2H_5OH is alcohol.

3. Sulphur is found in nature in sulphates, sulphides, in proteids (particularly the keratins), and also free.

4. $2NaCl + MnO_2 + 2H_2SO_4 = MnSO_4 + Na_2SO_4 + 2H_2O + Cl_2$.

5. Lunar caustic is silver nitrate, $AgNO_3$.

BACTERIOLOGY.

1. *Bacteria most commonly found in suppurative processes: Staphylococcus pyogenes aureus, Staphylococcus pyogenes albus, Staphylococcus pyogenes citreus, Streptococcus pyogenes, Streptococcus erysipelatis,* typhoid bacillus, genococcus, tubercle bacillus.

The *Staphylococcus pyogenes aureus* is a small round cell which appears in clusters like a bunch of grapes; its diameter is about 0.8 to 1.0 micron; it is facultative anaerobic, has no flagella, is not motile, it stains readily with the anilin dyes, and is not decolorized by Gram's method; it forms an orange pigment on gelatin, potatoes, and other media; it also liquefies gelatin.

Staphylococcus pyogenes albus is about the same as the *Staphylococcus pyogenes aureus,* except that it does not form a pigment, and its colonies are of a white color.

Staphylococcus pyogenes citreus is about the same as the *aureus* and *albus*, except that its growth is of a lemon yellow color.

The *Streptococcus pyogenes* is a micrococcus, of spherical shape, and arranged in chains of about thirty or forty cocci (in liquid media), but the chains are much shorter in solid media. Each coccus is about one-half to two mikrons in diameter. It is not motile, does not form spores, does not liquefy gelatin, and stains readily with the ordinary anilin dyes, and by Gram's method.

Bacillus typhosus is a rod-shaped organism, with rounded ends, is from 2 to 4 microns in length, and about three-fourths of a micron in breadth; it does not stain by Gram's method, but stains with all the anilin dyes; it has flagella, no spores, is aërobic and facultative, aërobic, and is motile.

Streptococcus erysipelatis appears in chains of varying lengths or in tangled masses, the presence or absence of oxygen does not seem to be of much importance, it grows at room temperature, and has the cultural characteristics of the *Streptococcus pyogenes.*

The *Tubercle bacillus* is rod shaped, is from 1½ to 3½ microns in length and about one-third to one-half a micron in breadth, is a strict parasite, is not motile, and has no flagella. It is slightly curved, does not form spores, is not liquefying, and nonchromogenic, is aërobic; it resists acids; it grows well on blood serum; stains well by Ehrlich's, Ziehl-Nielsen's, or Gabbett's method; it is Gram-positive.

The *Gonococcus* is a diplococcus with a special predilection for the mucous membrane of the urethra; it is sometimes found on the conjunctiva. The appearance is that of two coffee beans; the gonococcus is found in the pus cells, stains with ordinary anilin dyes, but not by Gram's method. It is aërobic, and can be cultivated on human blood serum; it will not grow on gelatin, agar, bouillon, or potato. It was discovered by Neisser.

2. *The three subdivisions of the colon typhoid bacillus group* are thus given by Jordan:

(1) *Bacillus coli;* the capsulated bacteria.

(2) The *Bacillus enteritidis* group, including *B. choleræ suis, B. icteroides, B. psittacosis,* and various "paracolon" and "paratyphoid" bacilli.

(3) *Bacillus typhosus* and *B. dysenteriæ; B. fecalis alkaligenes.*

3. *Phagocytes* are cells (notably the polynuclear and mononuclear leucocytes) which have the faculty of taking up and destroying bacteria.

Blastomycetes are yeasts; they consist of spherical or oval cells, and increase by sporulation or budding.

Thermal death point is the degree of heat necessary to kill any given bacteria.

Antiseptics are agents which retard or prevent putrefaction.

Disinfectants are agents which kill bacteria and their spores.

4. For *diphtheritic throat* see French's "Practice of Medicine" (1910), page 191; or Osler's "Practice of Medicine" (1909), page 200.

To *obtain a culture:* A sterile swab is rubbed over any visible membrane on the tonsils or throat, and is then immediately passed over the surface of the serum in a culture tube. The tube of culture, thus inoculated, is placed in an incubator at 37° C. for about twelve hours, when it is ready for examination. A sterile platinum wire is inserted into the culture tube, and a number of colonies of a whitish color are removed by it, and placed on a clean cover slip, and smeared over its surface. The smear is allowed to dry, is passed two or three times through a flame to fix the bacteria, and is then covered for about five or six minutes with a Loeffler's methylene-blue solution. The cover slip is then rinsed in clean water, dried, and mounted. The bacilli of diphtheria appear as short, thick rods with rounded ends; irregular forms are characteristic of this bacillus, and the staining will appear pronounced in some parts of the bacilli and deficient in other parts.

5. See French's "Practice of Medicine" (1910), pages 108 and 396; or Osler's "Practice of Medicine" (1909), page 97.

PATHOLOGY.

1. *Lymphocytes* are small mononuclear leucocytes.

Poikilocytes are misshapen red blood corpuscles.

Blood-plates are small corpuscular bodies found in the blood, without hemoglobin, and supposed to be concerned in the formation of thrombus.

2. See French's "Practice of Medicine" (1910), page 529; or Osler's "Practice of Medicine" (1909), page 735.

3. See French's "Practice of Medicine" (1910), page 555; or Osler's "Practice of Medicine" (1909), page 763.

4. See French's "Practice of Medicine" (1910), page 727; or Osler's "Practice of Medicine" (1909), page 437.

5 and 6. See French's "Practice of Medicine" (1910), page 208; or Osler's "Practice of Medicine" (1909), page 214.

7. See French's "Practice of Medicine" (1910), page 70; or Osler's "Practice of Medicine" (1909), page 65.

8. An *antitoxin* is a substance formed in the body, of a protective character, and capable of rendering inert the poisonous products of bacteria.

9. See Rose and Carless' "Surgery" (1908), pages 723 and 722.

10. *Immunity* is the power of resistance (either natural or acquired) of cells and tissues to the action of pathogenic bacteria.

THERAPEUTICS AND PRACTICE.

1. See French's "Practice of Medicine" (1910), pages 481, 500, and 509; or Osler's "Practice of Medicine" (1909), pages 28, 38, and 30.

2. See French's "Practice of Medicine" (1910), pages 962 and 542; or Osler's "Practice of Medicine" (1909), pages 426 and 750.

Marasmus is malnutrition with general disturbance of the digestive and vital functions.

3. VERATRUM *is contraindicated:* In gastric catarrh, and in cardiac weakness.

Therapeutic action: "As a circulatory depressant, given early, in croupous pneumonia, pleurisy, hepatitis, maniacal delirium, etc., with strong, bounding pulse and other sthenic conditions; in puerperal convulsions and the early stage of peritonitis, phlebitis and other inflammatory affections of the puerperal state; also acute rheumatism, tonsillitis, aneurysm, and wounds of the head, pericardium, and peritoneum."—(Wilcox, *Materia Medica.*)

4. See French's "Practice of Medicine" (1910), pages 7 and 996.

5. In *tetanus,* the onset is gradual, is apt to begin with trismus, swallowing is difficult or impossible, the condition is persistent, consciousness is dulled or lost, and there is history of a wound or injury. In *strychnine poisoning,* the onset is more sudden, the muscles of the jaw and neck are generally the last to be affected, there are marked remissions with muscular relaxation, consciousness is retained, and there is no history of a wound or injury.

6. See French's "Practice of Medicine" (1910), pages 984 and 1111.

7. See French's "Practice of Medicine" (1910), pages 943 and 948; or Osler's "Practice of Medicine" (1909), pages 389 and 393.

8. See French's "Practice of Medicine" (1910), page 1173; or Osler's "Practice of Medicine" (1909), page 1266.

9. In *mitral incompetency* there is a systolic murmur heard loudest at the apex, transmitted to left axilla, and is constant; *Functional systolic murmurs* are heard loudest at the base (or over the pulmonic area), are not transmitted, and are affected by the position of the patient.

10. *Aphasia:* loss (partial or complete) of the power of expressing ideas by speech or writing.

Apoplexy is the group of symptoms, including unconsciousness and paralysis, due to cerebral hemorrhage.

Thermic fever is the same as heat-stroke (symptoms due to exposure to great heat).

Myolgia is muscular rheumatism, or simply pain in muscles.

Fever is a condition characterized by rise of body tem-

perature, quickened pulse and respirations, increased tissue waste, and disordered secretions.

Parotitis is inflammation of the parotid gland (mumps).

Septicemia is septic intoxication with the presence of living pyogenic bacteria in the blood stream.

Pyemia is the same as septicemia, with the addition of the formation of secondary or metastatic abscesses.

Pachymeningitis is inflammation of the dura mater of the brain or spinal cord.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 515 and 509; or Hirst's "Obstetrics" (1909), pages 239 and 238.

2. See Williams' "Obstetrics" (1909), pages 507 and 518; or Hirst's "Obstetrics" (1909), page 263.

3. See Williams' "Obstetrics" (1909), page 816; or Hirst's "Obstetrics" (1909), page 577.

4. See Williams' "Obstetrics" (1909), page 254; or Hirst's "Obstetrics" (1909), page 395.

5. See Williams' "Obstetrics" (1909), page 661; or Hirst's "Obstetrics" (1909), page 442.

6. See Williams' "Obstetrics" (1909), page 325; or Hirst's "Obstetrics" (1909), page 607.

7. *Conditions warranting the induction of premature labor:* (1) Certain pelvic deformities, (2) placenta prævia, (3) pernicious anemia, (4) toxemia of pregnancy, (5) habitual death of the fetus toward the end of pregnancy, (6) hydatidiform mole, (7) habitually large fetal head.

The methods that may be employed are: Partial dilatation of the cervix and the introduction within the cervix (and vagina) of a tamponade of sterile gauze; (2) dilatation of the cervix; (3) puncturing the membranes; (4) introduction of a soft rubber bougie into the uterus; (5) intrauterine injection of glycerin, water or some other fluid.

8. See Williams' "Obstetrics" (1909), page 400; or Williams' "Obsetrics" (1909, page 811.

9. See Williams' "Obstetrics" (1909), page 571; or Williams' "Obstetrics" (1909), page 111.

10. See Williams' "Obstetrics" (1909), page 321; or Williams' "Obstetrics" (1909), page 331.

DISEASES OF WOMEN.

1. Pruritus vulvæ may be *caused by:* Parasites; diseases of the vulva, as inflammation, edema, vegetations, congestion, irritating discharges, lack of cleanliness, diabetic urine; it may also be of nervous origin or idiopathic. *Treatment* consists in removing the cause, if possible; cleanliness, fresh air, tonics, and general attention to hygiene; local applications of solution of bichloride of mercury, 1:2000; or carbolic acid, 1:100; or lead and opium; dusting powders of bismuth subnitrate, calomel, or zinc oxide are also useful.

2. In *appendicitis* the pain is of sudden onset and is localized in the right iliac fossa; there is abdominal rigidity, chiefly of the right rectus muscle, and tenderness at McBurney's point; there are usually fever, nausea, vomiting, and constipation.

In *inflammation of the right ovary* the pain is not localized, but may be bilateral, and spreads to the vagina and rectum; there is no tenderness at McBurney's point; it is usually worse just before the menstrual period, which sometimes affords relief; on vaginal examination the ovary is found to be tender.

3. *Most frequent causes of pyosalpinx* are: Gonnorrhea, puerperal septic endometritis, and sepsis from use of dirty instruments. It is *diagnosed* by: Pain or discomfort, made worse by pressure, examination, or defacation; colicky pains over the tube; dysmenorrhea; increased menstrual flow; tubes are found to be dilated and swollen. *Treatment:* Removal of the affected tube.

4. The INDICATIONS FOR HYSTERECTOMY are given as follows: *For the abdominal operation:* All solid or cystic tumors of the uterus; cancer; uterine rupture during labor; certain conditions of puerperal sepsis; pregnancy complicated by pelvic deformity, cancer, or other serious obstacle to the passage of the child; uterine prolapse or inversion, and, incidentally, as a step in the removal of complicated suppurative conditions of the uterine appendages.

For the vaginal operation: Bilateral suppurative conditions of the appendages; prolapse, cancer, pregnancy with cancer before the sixth month; certain septic conditions of the uterus; certain rare conditions which may require the ablation of a small movable uterus.

For the combined operation: Cancer; certain complicated fibroids; failure to secure hemostasis from below.—(From *Reference Handbook of the Medical Sciences.*)

Vaginal hysterectomy: "The patient is catheterized and placed in the lithotomy position and the external genitals are thoroughly disinfected. The vagina is held open by broad retractors and the uterus is pulled down by volsella forceps grasping the cervix, while the adjoining mucous membrane is cut well clear of the disease by blunt-pointed scissors. Keeping close to the uterus, the dissection is continued on its anterior and posterior surface by the tip of the finger and short snips of the scissors, but at the sides, after division of the mucous membrane, the cellular tissue is simply pushed up as high as possible, or till the pulsations of the uterine artery are felt. The finger is finally thrust through the uterovesical fold of peritoneum, and after cleansing the vagina flat sponges are poked in around the uterus. Douglas' pouch is entered in the same manner, hemorrhage from the vaginal wound being controlled by a few catgut sutures through its cut edges, and then the finger is hooked over the fundus, pulling it down into the posterior opening and thus bringing within reach the upper border of the broad ligaments, which are seized by long-bladed clamps and divided on the uterine side. Other clamps are placed on the remaining tissues close to the uterus, which is then excised."—(Stimson's *Operative Surgery.*)

7. See Rose and Carless' "Surgery" (1908), page 483; or Da Costa's "Surgery" (1908), page 464.

8. See Da Costa's "Surgery" (1908), page 840.

9. See Rose and Carless' "Surgery" (1908), page 390; or Da Costa's "Surgery" (1908), page 1058.

10. See Rose and Carless' "Surgery" (1908), pages 1041 and 1050; or Da Costa's "Surgery" (1908), pages 853 and 861.

EYE, EAR, NOSE, AND THROAT.

1. IRITIS. *Symptoms:* Pain, photophobia, small pupil, ciliary congestion, discoloration of iris, exudate in anterior chamber. *Diagnosis:*

ACUTE IRITIS.	ACUTE CONJUNCTIVITIS.	ACUTE GLAUCOMA.
1. Pupil: small, sluggish, irregular after atropine.	Normal.	Dilated, oval, fixed.
2. Iris: swollen, dirty, lymph on surface.	Clean and bright.	Swollen and discolored.
3. Anterior chamber: normal (or deeper, with turbid contents).	Normal.	Shallow.
4. Cornea: clear (or with deposits on back).	Clear.	Steamy; *anesthetic.*
5. Ciliary region: injected.	Not injected.	Injected.
6. Conjunctiva: usually some injection.	Red, opaque, perhaps swollen.	Great congestion, perhaps chemosis.
7. Discharge: tears only.	Muco-pus.	Tears only.
8. Palpation: tension normal (occasionally + 1); tender in ciliary region.	Tension normal, not tender.	Tension + 2 to 3, very tender.
9. Pain: over forehead and nose, worse at night.	Sand or grit in eyes.	Intense neuralgia in and about eyes, nausea, vomiting.
10. Vision: clouded.	Scarcely affected.	Rapidly lost; field extremely limited; "rainbow rings" seen.
11. Disc: if seen, normal.	Normal.	If seen, cupped, and arterial pulsation.

Treatment: Causal abstraction of blood from temples, atropine, diaphoresis, shielding the eye from light.

"*Interstitial or parenchymatous keratitis:* The whole cornea becomes more or less opaque and has a ground-glass appearance. Pericorneal injection is present. Inflammations of the iris, ciliary body, and choroid occur as complications. The condition is of long duration and results in reduction of visual acuity. Pain, lacrymation, and photophobia appear as subjective symptoms. The treatment consists in the administration of tonics and stimulants, the use of the mercurials and iodids, attention to the diet and hygiene, cleanliness, and fresh air. Locally, instil atropine, apply hot compresses, and prescribe protective glasses. Later, massage with yellow salve and dusting with calomel are of advantage.

"*Phlyctenular keratitis* is usually associated with phlyctenular conjunctivitis in children of scrofulous diathesis, but may occur in others. It is characterized by one or more small cysts found on the limbus of the conjunctiva and extending upon the cornea. The symptoms are acute pain, photophobia, lacrymation, and the characteristic bundle of vessels, with a yellow crescent at the apex, its concavity toward the apex. Blepharospasm is present and may be severe. The treatment consists of good food, fresh air, and the administration of tonics and stimulants. Locally, atropin and warm compresses should be used, and the eye douched with mercuric chlorid solution 1:8000. Later, iodoform or calomel may be dusted in the eye and massage with the yellow salve may be practised. Absorption of the vessels may be hastened by the instillation of eserin, dusting with iodoform, and the application of a bandage."—(Gould and Pyle's *Pocket Cyclopedia.*)

2. FOUR ERRORS OF REFRACTION. (1) *Hyperopia,* in which the eyeball is shorter than normal, or the cornea or lens unduly curved, and so parallel rays of light are focused behind the retina instead of on it. It should be treated by a convex lens whose principal focus is at the far point of the hyperopic eye. (2) *Myopia,* in which the eyeball is too long, and so parallel rays of light are focused in front of the retina. It should be treated by the weakest concave lens which gives clear distance vision, and by reducing the amount of near work. (3) *Astigmatism,* in which the different meridians of the eye refract the rays of light differently. It is treated by a cylindrical lens properly adjusted; this should be worn constantly. (4) *Asthenopia,* in which there is present a group of symptoms due to eyestrain the result of refractive errors or fatigue of the ocular muscles. Treatment consists in attention to general health and the proper correction of refractive errors.

3. The burn on the *eyelid* may give rise to scars and deformities, such as ectropion, entropion, symblepharon, and sight may be endangered if the cornea is involved. Sweet oil or carbonate of sodium in solution should be applied at once; granulations may be stimulated by balsam of Peru or silver nitrate. In the *conjunctiva* symblepharon or ankyloblepharon may result. Treatment should be prompt, and consists in applications of oil, milk, solution of sodium carbonate. Egg film may be used to prevent the eyelids from sticking together.

4. *Treatment of hypopyon:* "In its early stage the ulceration may be cut short by the very frequent use of warm boracic lotion, or of perchloride of mercury (1 in 5,000). If there be infiltration around the ulcer the base should be cauterized with pure carbolic, and atropine ointment used. A generous diet and quinine internally are indicated, and if the pain prevents sleep a hypodermic injection of morphia may be useful in the evening. Never fail to examine the lacrymal sac, and if sepsis be indicated by regurgitation on pressure it should be combated by slitting up the lower canaliculus and washing out frequently with antiseptic and astringent lotions. If in spite of this treatment the ulcer spreads the edge of the ulcer should be cauterized with the galvano or a fine-pointed actual cautery. Or what is known as Saemisch's operation performed. This consists in the division with a Graefe's cataract knife of the borders of the ulcer, both puncture and counter-puncture being placed in healthy corneal tissue and the section (which opens the anterior chamber) is made to traverse the diseased area from behind forwards, crossing the ulcer at its center; or the incision may be made radially in the lower part of the cornea and directly into the hypopyon. Then the pus in the anterior chamber should be drawn out through the incision with fine forceps. Eserine is dropped in after the section has been made and mild antiseptic lotions employed. It is remarkable what relief follows this operation in many cases, the ulcer healing in the course of a week or two; but should it not be successful the wound may be opened daily for a few days with a fine probe and atropine used instead of eserine. Even if the ulcer heals satisfactorily a considerable nebula will be left, and should this obstruct vision a subsequent iridectomy for optical purposes may become necessary."—(*Aids to Ophthalmology.*)

5. In *follicular tonsillitis* the onset is more sudden; the temperature may be a little higher than that of diphtheria; there is no membrane, but the tonsils are red and swollen, and in the crypts are seen white cheesy spots or plugs which consist of broken-down epithelium, and are easily brushed away; Klebs-Loffler bacilli are never found.

In *diphtheria* the onset is more gradual; the temperature rises to about 101° to 103° F.; the tonsils are not much enlarged; there is an exudate of a thick grayish membrane which is very adherent, is removed only with difficulty, and leaves a bleeding surface; this membrane soon reforms, and may be found on the fauces and pharynx as well as on the tonsils; in the exudate the Klebs-Löffler bacilli may be found.

And see French's "Practice of Medicine" (1910), page 735; or Osler's "Practice of Medicine" (1909), page 447.

6. See Rose and Carless' "Surgery" (1908), page 868.

7. See Cunningham's "Anatomy" (1909), page 753; or Gray's "Anatomy" (1908), page 1163.

The function of the Eustachian tube is to conduct air to the tympanic cavity and to act as a drainage canal for the middle ear.

8. See Cunningham's "Anatomy (1909), page 720; or Gray's "Anatomy" (1908), page 1109. And see Rose and Carless' "Surgery" (1908), page 828.

9. See Rose and Carless' "Surgery" (1908), page 754; or Da Costa's "Surgery" (1908), page 766.

10. *Three common causes of deafness:* Impacted cerumen, inflammation of the middle ear, and perforation of the membrana tympani.

Treatment consists in removing the cause, if possible. See Rose and Carless' "Surgery" (1908), page 881.

SKIN AND GENITOURINARY.

1. See Rose and Carless' "Surgery" (1908), page 121; or Da Costa's "Surgery" (1908), page 200.

2. "*Erythema multiforme* is an inflammatory disease of the skin characterized by symmetrical, bright or dark reddish, more or less variegated macules, papules, and vesicles, occurring discretely or in patches, often sharply defined, and marginate, of various size and shape, running an acute course (Duhring). Constitutional disturbance usually precedes or accompanies it, and is manifested by feverishness, malaise, rheumatoid pains, anorexia, etc. This is followed by the sudden appearance of the eruption which may consist of macules, papules, vesicles, or blebs, the eruption being designated by the predominant type of lesions. It is bright or dusky red in color at first, but soon becomes purplish or bluish and shows a great predilection for extensor surfaces such as the backs of hands and dorsal surfaces of the feet. Other portions of the body, however, are not exempt. The subjective symptoms are itching and burning. In all cases the administration of fractional doses of calomel followed by a saline is of benefit. Quinine and the salicylates often serve to hasten the eruption's involution and to relieve the constitutional manifestations. Locally, antipruritic lotions are of value."—(Hughes' *Practice of Medicine.*)

3. See Rose and Carless' "Surgery" (1908), page 403; or Da Costa's "Surgery" (1908), page 230.

4. See Rose and Carless' "Surgery" (1908), page 402; or Da Costa's "Surgery" (1908), page 1055.

5. "*Acne vulgaris* is an inflammatory disease of the skin occurring in and around the sebaceous glands, characterized by papules, pustules, or tubercles, affecting chiefly the face, and running a more or less chronic course. Puberty, gastrointestinal disorders, menstrual disorders, uterine disease, anemia, and general debility are etiological factors. Bromides and iodides internally and tar externally may produce acne.

General treatment is of importance. The underlying cause should be ascertained and treatment directed toward it. The gastrointestinal tract is usually at fault, for which the following is recommended:

℞ Iron sulphate, gr. 16.
Magnesium sulphate, ʒi.
Dilute sulphuric acid, ʒi.
Peppermint water, ʒiv.
Tablespoonful in water before breakfast.

Local treatment: Sulphur is the sovereign remedy. The following formula is also used extensively:

℞ Zinc sulphate, Potassium sulphide } each, ʒi.
Rose water, q. s. ad ʒiv.

The ingredients are dissolved separately, then mixed. The lotion should be applied at night."
—(Gould and Pyle's *Pocket Cyclopedia.*)

MEDICAL JURISPRUDENCE.

1. In *death by drowning:* The surface is pallid, the face appears tranquil, the eyes and mouth being partly open. The skin often has the appearance known as gooseskin, and, if the body has lain upwards of twelve hours in the water, that of the hands and the feet is sodden by imbibition. The most important external sign is the presence on the mouth and nostrils of a fine froth (possibly blood stained) composed of air, mucus, and the medium in which drowning took place; if the body remains three or four days in water the froth disappears. Exceptionally, fragments of weeds or other small objects may be found tightly grasped in the hands. On opening the thorax the lungs, gray in color, with reddish staining, are seen to be very voluminous, a condition known as ballooning, partly due to infiltration of the lung tissue with some of the medium in which drowning took place, and partly to true edema. The lung substance is inelastic and pits on pressure. On section fluid and froth resembling that found on the lips exude from the divided air passages. Minute subpleural hemorrhages are not infrequently present, and the pleural cavities may contain fluid. The stomach often contains water or other liquid which was involuntarily swallowed during attempts at respiration. Occasionally some of this fluid is forced by vital action into the intestines. With one exception, the remaining appearances are those met with after death from asphyxia. The exception is constituted by the blood, which is not only dark colored and fluid, as is usual after death from asphyxia, but is also diluted by the imbibition of water from the stomach and lungs.—(From Quain's *Dictionary of Medicine.*)

2. If cause of death is unknown or suspicious (possibility of either homicide, or suicide or other crime) it is the duty to discover the *cause of death* (it is no part of his business to discover the individual who caused it). He calls a jury to view the body and establish its identity; an inquest is held, witnesses are examined, possibly an autopsy is performed, and the jury renders a verdict.

3. To procure the commitment of a person to the hospital for the insane in South Dakota: "Application must be made in writing in the nature of a verified information alleging that the person on whose behalf the application is made is believed to be insane and a fit subject for custody and treatment in the hospital. The grounds of the information shall thereupon be investigated by the commissioners. They may require that the person be brought before them and examined, and may issue their warrant therefor. They shall hear testimony for and against the application, if any. Any citizen or relative of the alleged insane person may appear by counsel. The commissioners shall appoint some regularly practising physician of the county, who may be of their own number, to make a personal examination touching the truth of the allegations in the information and the actual condition of such person, and report to them thereon. On the return of the physician's certificate the commissioners shall conclude their investigation and find whether the person is insane and a fit subject for treatment and custody in the hospital. If he is found not insane they shall order his discharge. If insane they shall issue their warrant authorizing the superintendent of the hospital to receive such person as a patient."—(Witthaus and Becker's *Medical Jurisprudence.*)

4. It is, probably, not possible to distinguish absolutely human blood from that of other mammals. By careful measurements of the red corpuscles under the high powers of modern microscopes human blood can be readily distinguished from that of *some animals;* but in other cases, such as the differential diagnosis between the blood of a man and that of a dog, there is no absolute certainty.

5. See OBSTETRICS, 7.

HYGIENE AND SANITARY SCIENCE.

1. See French's "Practice of Medicine" (1910), page 194; or Osler's "Practice of Medicine" (1909), page 207.

2. Infantile paralysis is infectious; but how the disease is transmitted is not known, hence no rules have been formulated for "the protection of the community." It may be carried by contact, insects, "carriers," or along the line of travel. Isolation and quarantine would seem to be indicated, as in the case of scarlet fever.

3. Incubation period of *scarlet fever* is about 2 to 7 days; of *diphtheria* about 2 or 3 days; of *variola* about 12 days; of *measles* about 9 or 10 days.

4. See French's "Practice of Medicine" (1910), page 396; or Osler's "Practice of Medicine" (1909), page 352.

5. *Concerning schools:* The school building should be as near as possible to the center of the area which it is to serve; the site should be airy and open, of sufficient size, free from swamps, and somewhat elevated; it should not be too near factories, busy streets, or railways; the soil should be as free as possible from organic matter. The building should be so planned that the corners look towards the four points of the compass. In this way the sun will have access to each side and to every room during some part of the day. The building should have as few stories as possible. The walls should be of brick or stone, and should be pointed with cement; the inner surface of the wall should be cemented smooth. The foundations must be solid. The general arrangement will depend upon size of site, number of scholars, and number of required rooms. Fifteen square feet per child should be allowed. Details will have to be considered on: plans, accommodations to be provided, shape and size of class rooms, distribution of rooms, teachers' rooms, corridors, entrances and staircases, playground, ventilation, heating, lighting, and placing of windows, sanitation, lavatories, water supply, drinking water, sewage disposal, removal of refuse, sanitary appliances, and drainage. Special care must be given to the prevention of contagious diseases, and the exclusion of all possible sources of infection or contagion; there should be physical examination of children, also, for non-contagious physical defects.

The principal means of preventing the spread of contagious diseases in schools are: Regular and efficient inspection by physicians; prompt exclusion and isolation of anyone suffering from a contagious disease, or coming from a house where such disease is; compulsory vaccination; compulsory notification of all infections and contagious disease; individual towels, drinking vessels, and other implements; children who have had a contagious or infectious disease, or who have come from a house where such disease prevailed, should not be readmitted to school until sufficient time has elapsed since the occurrence of the last case to insure safety.

BULLETIN OF APPROACHING EXAMINATIONS.

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†	
Alabama*	W. H. Sanders, Montgomery.	Montgomery	July 11
Arizona*	Ancil Martin, Phoenix	Phoenix	July 5
Arkansas	F. T. Murphy, Brinkley	Little Rock	May 9

MISTAKES IN THE DIAGNOSES OF CHRONIC LESIONS.

THEIR CAUSES AND PREVENTION, BASED ON SOME ILLUSTRATIVE CASES OF CHRONIC LESIONS, INVOLVING THE MID-LOWER ABDOMEN AND PELVIC REGIONS.

By W. A BARTLETT, M.D.,

NEW YORK.

An early diagnosis in any chronic symptom presented is, I believe, the objective point in the diagnostician's art, and one to which our patient is entitled on his advent into the diagnostic arena. It is a matter of common experience, however, in spite of the improvement in the range and accuracy of the diagnostic methods which specialization has effected, that before such a presentment the units of the medical world, *i. e.* the practitioner, the specialist, and, of course, the unclassified members of the healing cult, too frequently break down, from a diagnostic point of view; the patient not getting what he is entitled to at first hand—a diagnosis which will stand the test of the remedial measure adopted.

Some clinical experiences encountered in the line of work having served to emphasize the frequency of these mistakes, the writer proposes to use them as a basis for a few observations on some of the most obvious causative factors of such failures, and to demonstrate thereby as well the diagnostic methods by which they can, in most instances, be prevented. Although those selected are limited in this paper to chronic gross lesions involving the mid-lower abdomen and pelvic regions, the conclusions to be drawn therefrom are universal in their application to chronic symptom presentments in general.

Any consideration of the factors accountable for these mistakes, to be conclusive, must include not only the symptom characteristics of chronic lesions, as we know them to-day, but the part the patient plays in response to them, as well as the prevailing diagnostic methods under which they occur.

First, directing our attention to the former. It is necessary for our purpose, that of illustrating the pitfalls provided for us by some of these characteristics, to limit our observations to their salient features only. In this connection, then, we will merely recall the trite fact that the symptoms of a chronic lesion may be the direct or the indirect, and that in typical forms these are observed in their proper relationship of cause and effect. Here, then, direct symptoms definitely locate the organ or structure involved, and upon them as an index an examination is made and the lesion revealed. The indirect symptoms, under these circumstances, representing the remote consequences of the lesion, belong to the category of constitutional or reflex reactions, and do not in any way affect the diagnosis.

A classical picture this, of a typical symptomatology, or what we have regarded as such, but one that is usually associated with terminal conditions only. Seldom do we encounter this, however, as we now have reason to know through the findings provided by the *x*-ray, laboratory analyses, and other specialized sources of information. In the light of these we are in a position to revise our textbook idea of symptoms, in accordance with the facts thereby revealed—which are to the effect that chronic gross lesions do not always present, in their earlier or even later stages, a typical symptom complex; *i. e.* the direct symptoms are either absent or are of so insignificant or unpathognomonic a character as to be overlooked, the indirect ones being the most obvious presenting phase for the time being. Particularly is this true of those involving some one of the abdominal or pelvic organ contents. In this most fertile soil of symptom complexity we are in a region abounding in such manifestations, a lesion in one being frequently expressed largely by a reflex in another; or in symptoms apparently unrelated to any abdominal lesion whatsoever. As an instance of the former, witness the effect of the vesicorenal reflex, when a lesion or irritation of the vesical neck is reflected in lumbar symptoms, or *vice versa;* or, in the latter, in disturbances of the central nervous system that are manifested in one or the other phases of the neurasthenic complex.

In the absence, then, of direct symptoms pointing to the causative lesion, these reflex or constitutional reactions are to the fore, and be they of the former or latter category it is on some one of them as a leading symptom, or symptoms, that our patient seeks relief.

Right here on the threshold of the diagnostic arena we encounter the second reason for these belated diagnoses, in which the patient and the prevailing diagnostic method to which he is subjected both play their parts.

In regard to the former, he is an innocent victim, for the reason that, in this age of specialization and healing cults of various kinds, he has on the one hand been taught to regard himself as a combination of many independent compartments, with a specialist for every one; on the other, the persuasive doctrines in connection therewith enthrall him. In either case, he is no longer the disciple of orthodox Æsculapian authority, and is the arbiter of his own choice in the matter of health.

In regard to the latter, *i. e.* the prevailing methods under which mistakes occur, he is now in the hands of his advisers, and when exercising his prerogative in regard to a choice of these the one selected is usually identified with the character or location of the predominate symptom—that is, with the treatment of the region our patient thinks is affected—who is, of course, a specialist, the practitioner

having become an almost negligible factor in this respect—at least in urban life. If, on the other hand, he is emancipated from these circles, science, or some one of its correlative competitors, is ready for him; whichever it be, a very important factor these advisers are in determining the immediate clinical career of the case. For the reason that with such a symptom range in mind, the clinical picture is, as likely as not, a typical in character of any well-defined lesion; or, as has been said, of any abdominal lesion whatsoever—of which many interpretations might easily be made, dependent upon the dominant phase at the moment and the care with which the case is worked out. The probable misinterpretation, therefore, of such a complex is directly proportionate to the readiness with which this phase is accepted as representing the whole story. This is exactly what is done in so many instances, particularly if some abnormality be found that might explain the symptoms, but which is not the primal causative lesion.

The lay systems are, of course, always guilty of such methods, recognizing no symptom as such except in circles where they have combined with accredited medical men. Less frequently are the practitioners accountable on these lines; and still more rarely is the specialist of training and judgment, but whose weakness, if it may be so termed, lies in his proneness to judge of symptoms from the standpoint of his specialty only.

The therapeutic or remedial failure resulting from procedures based on such insufficient findings may be one of a number of experiences of a like nature, through which our patient trails his way, if similar methods prevail—a range which may include the units of the medical world and the lay systems as well, in rotation respectively, or some of them at work on the case simultaneously. For it must be remembered that in this experience our patient continues to regard himself as the best judge of whom to consult, and goes from one to another on his own responsibility, without regard to the diagnosis or treatment of the previous one. A belated diagnosis is, we will say, finally secured by some one of the above units under a properly conducted technique, or by a frank terminal declaration in which the condition is usually an obvious one.

Quite an exaggerated picture this, apparently, but not inconsistent with the facts, as will be demonstrated shortly.

It follows, therefore, if such mistakes are to be avoided in most instances (and there are cases where this qualification applies) that in these days of reflex symptoms and direct symptomless lesions a fixed diagnostic technique should be adhered to under all circumstances, the essentials of which are comprised in the two succeeding well-known axioms:

First, that in every symptom presentment a diagnosis by exclusion should be an obligatory preliminary to any remedial measure, however trivial the symptom may be, or however unrelated to any gross lesion.

Second, that such a diagnosis should not be regarded as an accomplished fact until all the etiological factors have been revealed by careful inquiry, and their bearing on the case determined through the findings obtained by the aid of all the various specialties, which, in the judgment of the man in charge, are deemed necessary.

With the above consideration in mind, it is now the purpose of the writer to adjourn to the consultation room, where some clinical portraits of the lesion selected will be submitted. In order to preserve the realities prevailing under actual conditions, as cases come and go, these will be presented from the standpoint of their leading symptoms only, the significance of which, in respect to a gross lesion, being left for us to determine in accordance with the facts revealed by the diagnostic routine to which they are subjected.

It will be instructive, I trust, to see how the histories of these portraits tally with the skeleton outline above briefly sketched.

The first exhibit in our galaxy of belated diagnoses is a man of fifty, whose leading symptom is an almost daily afternoon fever of 100 to 101 degrees. He has had this six months off and on, and as a final explanation of this symptom he has been given a diagnosis of intestinal indigestion. Three consultants have been seen by him on his own selection, and all have treated him independently at various times, but he still has the fever, although otherwise in good health. He is a symptomless man, unless trivial minor indigestion and gas formation can be called symptoms. They are, however, and important ones, too, if his previous advisers did but know it; as, failing to recognize this signpost pointing to a possible abdominal lesion, they wasted their time in useless procedures.

In two months we were ready with a diagnosis of chronic appendix infection and prepared to rid him of his fever, which was done by the removal of an adherent appendix.

Time and the patience to convict him on the abdominal findings alone were the essentials of this diagnosis—which were based on the fact that painful responses were constantly obtained by palpation over the appendix and right lumbar ganglia. Without an acute episode in retrospect one has to be sure of one's digits, and the training to correctly interpret the findings thereby revealed in order to justify a laparotomy in such cases. Lacking this, some one should be cooperated with who can meet these requirements.

A similar leading symptom we are asked to explain by our next case, a woman of twenty-five, whose fever is higher but less frequent. She came to us fresh from the hands of three medicos, who were all treating her at the same time. Her chest had been looked after by an internest; a possibly prolapsed ovary received the attention of a gynecologist; and enlarged tonsils had their attention also. She is quite nervous in consequence. Her associated symptoms of cough and gastric restlessness, etc., afford a very perplexing medley which well nigh efface the important direct symptoms of smart colicky episodes with intermittent appendix region soreness. On these and similar methods of repeated abdominal examination as were employed in the previous case a relative diagnosis of chronic appendix infection was made. The relief of that condition was surgically paramount, leaving the question of its relationship to temperature fluctuation for the future to decide. It did, in the affirmative, after an adherent appendix was removed and the colon released from its enmeshing adhesions.

Apologies are due for introducing these trite chronicles. It will be observed, however, that now, as formerly, such lesions are as ready to trick the unwary, when the presenting symptom is so unrelated to an abdominal lesion.

The leading symptoms in our next instance, a man of forty, are scalding on urination, rectal and blad-

der pain, with vesical storms thrown in. These are of comparatively recent date—about two years' duration—and with their advent his prostatic era began, and his troubles also. Prior to this we find that an irritable bladder all his life, and a diagnosis of Bright's made five years ago, comprise the essential details of his remote history. These are, comparatively speaking, of no importance in his mind. The former, on the contrary, have occasioned him a great deal of suffering and given him much concern, as well they might when one learns that he has at different times seen five medicos, all consulted independently by him, all treating him equally so. He cannot understand why, under such unquestionable medical auspices, he has steadily grown worse. He has had several diagnoses given him, ranging from the Bright's above mentioned to the last, under which he comes to us, viz., chronic cystitis and prostatitis. His therapeutic experiences run the gamut of conventional procedures, directed to his bladder and prostate, to the final advice, according to his understanding, of incision and drainage. At that he blew up and has refrained from treatment since.

So scared is he now of manipulation that he reluctantly submits to a prostatic examination. Chronic infection of this gland ought not to be made worse by treatment, unless malignant or possibly tuberculosis in character. This, and the fact that the gland did not appear to be much involved, and that the urine contained evidence of a pyelitis, justified a diagnosis of this character, possibly of a calculus nature pending an *x*-ray photograph. Dr. L. G. Cole reported later, as a result of this, five stones in the left kidney, which were removed by Dr. George E. Brewer.

In the absence of direct symptoms in this case, there being no history of renal colic or hematuria, his previous advisers were caught in the toils of the vesicorenal reflex, whereby their attention was riveted on the lower genital tract by symptoms involving, apparently, this region only. Easily led astray are we under such circumstances, unless the *x*-ray is employed in all bladder cases, as a routine measure.

The healthy appearance of this woman of thirty, our next illustration, gives the lie to possible suspicions of serious trouble. Quite prepared are we, therefore, to find that her leading symptoms are trivial. They are headaches, some indigestion, and a facial acne; all of two years' duration, off and on. These are due to intestinal indigestion, "our old friend," she has been told by her previous advisers, four in number. She wears glasses in consequence of one; she has her eruption and dyspepsia in spite of the others, including the last, an ex-science healer. A persistent facial acne appearing at twenty-eight, in so clear-skinned a woman, arouses suspicion at once, and demands an explanation other than the one accepted. Then, too, she is losing weight, we are told. The second diagnostic essential in this case is a pelvic examination, because our first one, her history record, gives us a vague outline of colic, irregular menses, and slight leucorrhea.

Not pathognomonic these, but we do not believe in unpathognomonic symptoms as a basis for diagnostic beliefs, without the objective findings in our possession. The difficulty of maintaining our technique intact is now apparent, as she persistently refuses to comply, on the ground that she is well in this respect, and merely to accept it as a routine measure does not appeal to her. Possible lesions can easily escape detection in this way, if the clinician is dissuaded from his intent. She finally yielded, however. Surprises are repugnant to the scientific mind, but we had to acknowledge one here, however, in the discovery of a bilateral pysoalpinx. She lost both ovaries in consequence.

Healthy looking women with trivial symptoms do not always have such a lesion, but one never knows, and had better be protected behind a routine schedule than be caught as the others were. On this basis, some gynecologist in the past might have been in time to spare some ovarian tissue, and save her an induced menopause at thirty.

Following this we have a woman of thirty-five who is in bed. There is evidently some serious pathological indictment here, as her face is drawn and thin, and she is short of breath; and well she might be, as we find, on cursory examination, the abdomen fully distended with fluid. Cirrhosis and renal etiological possibilities occur to one immediately, to be dismissed, however, when we learn that the distention appeared two weeks ago, the second week after she had begun treatment with an osteopath for neuralgia of the left shoulder—her then leading symptom. Exhaustion, dyspnea, etc., compelled her to stop treatment a week ago.

Proceeding on the routine plan, there is, in spite of the distention, a tender mass detected in the lower left abdomen—easily outlined on vaginal examination as well. A diagnosis of ruptured ovarian cyst, possibly colloid or papillomatous in character, with Dr. H. C. Coe and Dr. George E. Brewer in consultation, was defined on operation to be of the latter variety, the rupture of recent date having been followed by a rapid peritoneal involvement, the parietal and visceral peritoneal surfaces being covered with seed-like exudates of a similar pathological nature.

This case emphasized the necessity of a careful history record again as the first diagnostic essential, which record would have revealed that a mass involving the left tube and ovary had been found on examination some time ago. If this had been done by the previous advisor, and a pelvic examination made an obligatory procedure to contemplated treatment, we would not have had to deal with the consequences of a ruptured ovarian cyst.

In fragile women such physical strains and stunts without all the obtainable information in regard to their economy in our possession are apt to be hazardous indulgences.

The symptom reactions in the foregoing cases are, in a sense, physical in character, the element of some preexisting nerve infirmity playing no part. We could not go far in the clinical field, however, without encountering those problems to which the term functional, as it is commonly employed, is used to account for symptoms apparently unassociated with any gross lesion. These are the victims of the so-called neurasthenic complex, with its symptom variations. Admitting that these can be explained in part on the basis of a preexisting nerve instability, in many they cannot, the clinical presentment being, on the contrary, the exaggerated expression of pathological changes, which a thorough examination will reveal. In the absence of some definite findings of this character, to separate the warp of that which is due to functional causes from the woof of that which is due to an ill-defined pathological condition will tax the clinician's capacity for differentiation to the utmost. With these doubt-

ful cases we will not concern ourselves in this paper, limiting our observations to those phases in which the syndrome can be accounted for by a well-defined lesion. It will be interesting to observe how the reactions of this type to the irritation or toxemia resulting from such a cause plays havoc with the diagnostic reputation of those in charge, in that the clinical picture in no way resembles one's idea of how the causative lesion should and ought to behave.

Our first example under this heading, an ill-looking woman of thirty-five, belongs, we will say, to that vague zone of character classification above alluded to—the neurotic type. Let us see what are the basic facts of this classification as applied to her leading symptoms. These are, that her bowels are blocked and in danger of strangulation, in proof of which she refers to her abdominal distention. She is very hysterical, so her family states, will not eat, and does not sleep. Last year she was in a much worse condition with similar symptoms, as a result of which she was committed to an institution on a diagnosis of melancholia and neurasthenia —so we are told. Her medical advisers at the time made no examination calculated to lay bare any existing gross lesion. They were four in number, and all were consulted independently of each other by her family, and treated her so. She has been comparatively well after her discharge from the institution until the present time. Her reiterated assertion in regard to her abdominal symptom does indeed arouse suspicion in regard to her mental state, particularly as the external examination is without significant findings except some sensitiveness in the lower abdominal plane. There are several facts in her history, however, justifying a pelvic examination as a preliminary to any action. These are: an uneventful juvenile record, culminating four years ago in an attack of peritonitis, following which we have periods of nervousness and frank hysterical storms; that her symptoms last year were associated with menstrual irregularity and prolonged dribbling: that in the institution, as the former disappeared, so did the latter, to return again now when similar complaints are in evidence.

The result of this examination—a fixed uterus, and a mass involving the left tube and ovary—gives us something definite to act upon, irrespective of what the relationship may be between them and her mental condition. Upon removal by Dr. Clement Cleveland, this mass was found to present the characteristics of an inactive pyosalpinx, the existing extensive adhesions bearing testimony to recent and remote periods of activity. Her past operative period of exemption from the former symptoms established the associated relationship of cause and effect between that lesion and its consequences in one of so highly organized a temperament.

With these facts in our possession, in her earlier symptoms we see the beginning reaction of her unstable nervous system to the existing lesion: in her later abdominal ones, the commonly observed symptoms of like pelvic conditions, distorted, of course, by her mental state. It is fair to infer, therefore, that a pelvic examination on the threshold of her previous advent into the medical arena might have rendered an institutional sojourn inexpedient.

It was a great relief for her to find that her sensations and functional irregularities were due to actual conditions rather than being the vaporings of a distorted mind.

A similar diagnosis confronts us in our second instance, a high-strung man of fifty, the facts of which being that for several months he has been in a deplorable mental and physical state. In regard to the former, his phase takes the form of impending ruin, and, as a consequence, suicide is threatened. Of the latter, there is ample evidence in the loss of weight, the insomnia, and low food output, with alcohol props in consequence. On these leading symptoms he has sought the advice, at the instance of his family, of a number of men—the neurological and general medicine representatives of which include a psychotherapeutist, or some one of that character. On inquiry we find several facts that demand explanation before he is sent to an institution, for that has been advised by the former; or submits to further treatment of the suggestion order by the latter. These are: a Bright's disease indictment five years ago, and a record of frequent "colds" of late, as expressed in right side lumbago and vesical irritability, with, he thinks, fever—all subsiding simultaneously. Enough these are to justify suspicions of some lesion in this tract, the nature of which can be in part defined by, first, an analysis by Dr. E. E. Smith, and an *x*-ray picture by Dr. L. G. Cole; the former reporting the findings of a pyelitis, and the latter the presence of a good-sized stone. The expediency of an institution was, of course, shelved until that condition was relieved, particularly as a now daily fever and a pulse rapidity with increasing lumbar soreness gave ample evidence of the septic condition prevailing; a conclusion verified in the immediate sequences following the operation, when, after a pyonephrotic abscess was emptied, due to a partially blocking stone in the upper uretal entrance, the persisting septic condition rendered the outcome doubtful for the moment.

The facts to be emphasized in this case are these: the absence of the classical phenomena, of hemorrhage, or renal colic, and a clinical presentment entirely unrelated to the causative lesion. In the absence of routine methods, of which a careful history record was the first essential again, and failure to have the urine findings interpreted correctly, we see his advisers on the rampage in their respective fields —treating symptoms and ignoring causes.

Laughable it is, were it not so tragic in its consequences, to think of trying to rid this man of calculus pyelitis by mental suggestion! His fixed idea fled with his toxemia after the operation.

The terminal effects of old infection, whether of a post-operative character or not, on the visceral and organ content of the abdomen and pelvis, are frequently made manifest in extensive adhesions, as we know, the resulting contraction of which produces an alteration in the anatomical relationship of the implicated structure of sometimes an extreme character. These we can define, in so far as they affect the colon and sigmoid, by the *x*-ray and bismuth test, whereby its position and mobility can be outlined under varying conditions; those involving the small intestine not being as susceptible to this method.

The advisability of employing this diagnostic essential we will now consider in differentiating symptoms, which, under older methods, were frequently misinterpreted, the associated complex being often attributed to functional causes only. It is under this cloak, partially, that this first instance, a woman of fifty, is submitted.

She is brought with a request for a fake operation, as she has the operation craze. The leading

symptoms for which this request has been made are just now localized in the lower abdomen. They are: pain, cramps, and obstinate constipation. Last year the throat was the objective point of complaint. The external abdominal examination reveals the picture of a pain case, no definite findings being obtainable thereby. In appearance she bears out the story—bad color and fat. She presents also the scar of a previous laparotomy which links her to a past record of double ovariotomy, with as many diagnostic placards, and as equally variegated, as her record of doctors and treatments. The two additional facts revealed in this case are that she is passing very small fecal masses only, and that enemas give her intense pain. These give us a definite line upon which to open our diagnostic fire, which will begin with an *x*-ray of her colon under the bismuth test by Dr. L. G. Cole; and, as can be seen by the accompanying photograph, we have an obvious condition upon which we can avoid a fake operation.

No. I.—AA, displaced sigmoid. B, descending colon. C, point of constriction. R, rectum.

On opening the abdomen, Dr. Dougal Bissell found the condition exactly as above outlined, the transverse section of the descending colon being constricted to the danger point by broad encircling adhesion bands.

The distorted and displaced sigmoid was fixed in the position indicated in the photograph, thus producing a reservoir for fecal accumulation—as did also the dilated gut above the constriction. These fully explained her local symptoms and her existing toxic condition, which was quite in evidence. The symptoms of preexisting nerve instability, whether acquired or of a hereditary character, in such cases are not entirely relieved, of course, by dividing adhesions and thus restoring bowel function. It was a satisfaction to find, however, that with this restoration a fairly workable plane of action was secured.

Of more import, however, is the fact that, disguised under such easily dismissed symptoms, there may exist conditions implying imminent danger to tissue integrity, the contraction of that adhesion band to the circulatory obliterative point being merely a question of time, the result of which the desire for a fake operation probably saved her.

The actualities of such conditions, advancing undetected, are presented in our last instance, a man of sixty-five, whose leading symptoms comprise the mental and physical responses to the later stages of an arteriosclerosis, a condition of marked neurasthenia and mental failure. Unnoticed at first, but quite obvious after he had been under the writer's observation, were the symptoms of pain and soreness in the right hypochondrium. An examination was finally made, and a movable, compressible mass easily outlined. The remote history of this mass gives a diagnosis of appendicitis ten years ago, and concludes with a later one of movable kidney, speculations in regard to the accuracy of which were dismissed in the course of observation by its disappearance under cathartics and an enema. This and the fact that the latter gave him agony left no

No. II.—A, displaced sigmoid. B, descending colon. C, sigmoid. R, rectum.

doubt of an existing sigmoid displacement somewhat similar to that of the previous case. The *x*-ray photo, by Dr. Cole, as can be seen, verified this diagnosis.

While considering the advisability of some course of action, symptoms of strangulation suddenly supervened, terminating the case abruptly, the point of strangulation being, it was found on autopsy, at the iliocecal junction, the entire ascending colon being gangrenous. This case does not, strictly speaking, belong under the last classification, as the relationship between his arterial condition and his general symptoms had been thoroughly understood. The point to be emphasized, therefore, is that in the case of his previous advisers, as well as the writer under whose observation a year had elapsed, the direct evidences of his intestinal complication had been dismissed as of no more import than his other complaints, the time for operative interference, if it

was at all to be considered, having in this way slipped by.

The clinical pictures associated with the lesions above presented comprise a wide assortment of symptoms of a heterogeneous order, as has been seen. Far away they may lead one from the actual cause. All the more necessary is it, therefore, for us to consider all cases guilty until proved innocent of some gross lesion, if we are to escape the indictment of a belated diagnosis.

In the prevention of this it will be well to keep the diagnostic sign-board illuminated with the fact that gross lesions can walk right up to a terminal event without a real so-called classical symptom. With this in mind, the consideration that should govern us in the interpretation of symptoms is the necessity of cooperation on the broadest lines under all circumstances. In this way the personal element, which exists too frequently to the detriment of our patient, is eliminated. If one has not the knowledge to clear up all the etiological factors, he should combine with those who can meet the requirements.

33 West Sixty-seventh Street.

ACUTE TONSILLITIS AND ITS TREATMENT.

By HAROLD HAYS, A.M., M.D.,

NEW YORK.

ASSISTANT SURGEON IN OTOLOGY, NEW YORK EYE AND EAR INFIRMARY.

The causation of acute tonsillitis is apparent in the majority of cases as soon as a culture from the tonsils is taken. Its primary differentiation must be made from diphtheria and Vincent's angina. Whatever contributing etiological factors are given, such as exposure to cold, environment, etc., the existing cause can be attributed to one thing only, namely, infection. The varieties of organisms which may cause the infection are numerous. We may enumerate the staphylococcus, streptococcus, *Streptococcus pyogenes,* and *Streptococcus capsulatus,* Friedlander bacillus, pneumococcus, etc., the streptococcus being the causative agent in over 80 per cent. of the cases.

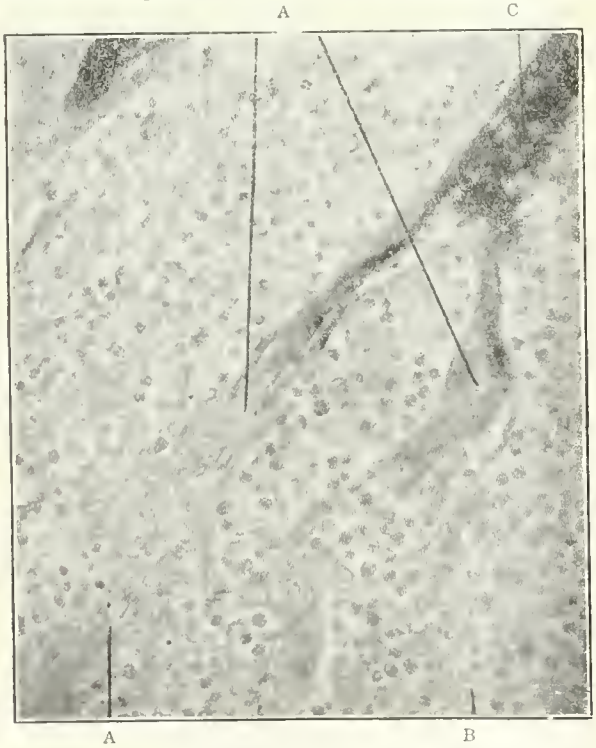

Fig. 1.—Normal faucial tonsil, showing terminal portions of crypt. Notice the keratosed material in the crypt and the penetration of epithelial cells in the tonsil parenchyma. A, cryptal epithelium. B, interfollicular lymphoid tissue. C, keratosed material. From Dr. Geo. B. Wood's article in the *Annals of Otology, Rhinology, and Laryngology,* March, 1909.

The symptoms and the pathology are too well known to be spoken of here. Our chief concern should be in differentiating it from diphtheria. This is not such an easy matter as one would suppose, unless the report of the culture is at hand. I have seen cases of acute tonsillitis with pseudo-membranes on the tonsils, resembling in every detail the picture of diphtheria. Per contra, I have seen cases of diphtheria with no membrane present, the crypts of the tonsils being filled with pus and the surrounding parenchyma highly inflamed. It is a good custom to take a smear and a culture in every patient who presents himself with a complaint of sore throat, where there is any sign of tonsillar infection. In not a few cases the smear will show diphtheria bacilli and so a day or more is saved in giving the antitoxin. I had an example of the value of such care in the case of a young woman who came to me last spring, saying that she had had a bad sore throat for three days. The patient was a servant in a family where she was placed in intimate contact with a young child. The throat was very much reddened and both tonsils were acutely inflamed. Every crypt was filled with pus. The systemic symptoms, not being severe, made me suspicious that the case was not tonsillitis; for with the throat in such a condition one would expect a high degree of fever with prostration. Before applying my usual treatment I took a smear and culture from one of the crypts. The smear showed a pure culture of a bacillus having the morphology of the diphtheria bacillus. I then applied treatment and sent for the Board of Health inspector. My diagnosis was corroborated by culture. It was only a week or so later that another patient came to me with precisely the same picture clinically and pathologically, but in this second case the lesion was due to a streptococcus. The differentiation from Vincent's angina is easier, although a culture must be taken to make the diagnosis abso-

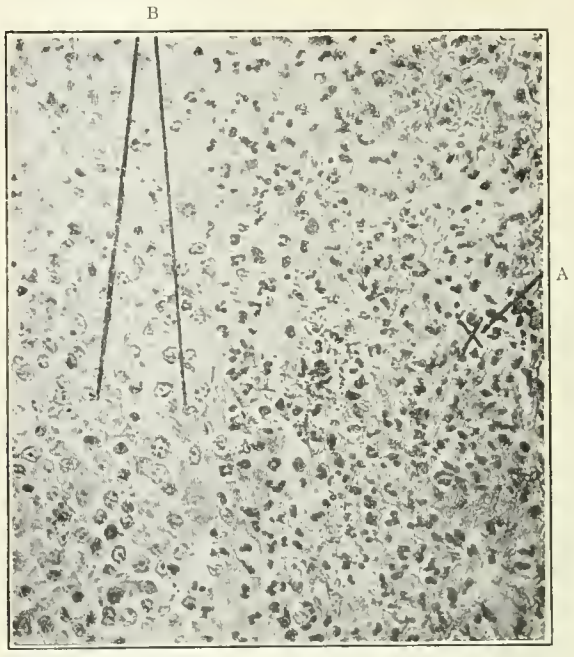

Fig. 2—Acute tonsillitis. Invasion of the cryptal epithelium. A, crypt filled with débris, numerous polymorphonuclear leucocytes, fibrin, and broken-down epithelial cells. B, epithelial cells. From Dr. Geo. B. Wood's article in the *Annals of Otology, Rhinology, and Laryngology,* March, 1909.

lute. The angina may affect any part of the throat, and if it should affect the tonsil the membrane would resemble that of diphtheria. I wish to mention it here so that when a smear is taken from a membrane on the tonsil and no diphtheria bacilli are found, one

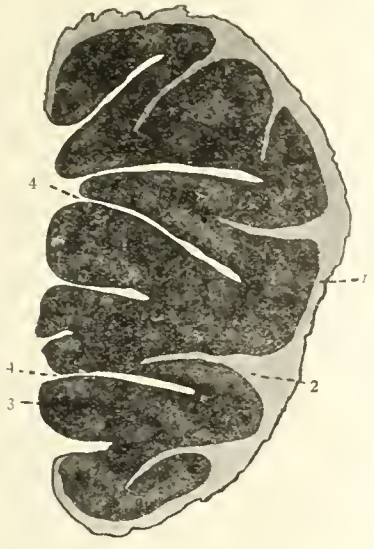

Fig. 3—Normal tonsil in cross-section. Note the even caliber of the crypts.

will keep in mind that the bacillus and spirillum of Vincent should be looked for before a diagnosis of acute tonsillitis is made. The ulceration and destruction in the later stages of Vincent's angina may thus be avoided by judiciously using Lugol's solution and silver nitrate.

The treatment of acute tonsillitis as practised by the general practitioner and the specialist are entirely different. This is mainly so because the family physician does not feel himself in a position to use strenuous measures which might inflict a great deal of local injury; moreover, facilities may not be at hand to examine the throat carefully, and under those circumstances no chances should be taken. There is no doubt that rest in bed, light diet, cathasis, gargling the throat with peroxide, iron, and glycerin mixtures, etc., will cure the majority of cases of tonsillitis. But it is unnecessary to confine a patient to the house for more than one day, and if he can be made to overcome the intoxication in a short time it is worth a great deal, particularly if he be a man whose every moment must economically be considered.

One must look at tonsillitis as a local disease causing systemic infection. If such be the case the patient must primarily be treated locally. Our first object, then, is to destroy the invading organism as thoroughly as possible. Moreover, spraying or swabbing the surface of the tonsil with antiseptics is worse than useless. The deeper infection in the crypts is much more important than the surface infection. (Figs. 1 and 2.) This is readily explained if one examines the two illustrations here presented. (Figs. 3 and 4.) In the first we see a tonsil in cross section, showing the crypts, lined with columnar epithelium dipping down into the tonsil, in places touching the root of the tonsil itself. Sometimes these crypts communicate. Their lining epithelium is very thin, and is immediately in contact with the parenchyma of the tonsil itself, which is composed mainly of mononuclear cells. Infection through these crypts, tuberculous and otherwise, has been fully explained by Wood, Wright, Hurd, Ballenger, and others. In the second we see an acutely inflamed tonsil with the openings of the crypts filled with pus and débris. Behind this the ostium is closed by the surrounding inflammatory reaction until the deeper portions are entirely closed off. Infection in these parts cannot be reached by swabbing or sprays. The crypts must be opened up in some manner which will allow of proper drainage. Many writers advocate the washing out of the crypts with antiseptic solutions by means of a cannula and syringe. I tried this procedure in a few cases by means of a special irrigating forceps, but desisted after finding out that I made the condition worse instead of better. Inserting such an instrument, even after applying cocaine, has a tendency to increase the inflammatory reaction. Moreover, one agent has been found which is almost specific in these cases of acute tonsillitis. I refer to silver nitrate in a strength of 50 per cent. Ballenger uses an even stronger solution and swabs it over the entire tonsillar area. My usual procedure is as follows: After taking a smear and culture of the tonsil the throat is thoroughly sprayed with some alkaline antiseptic to dissolve the mucus. Then it is again sprayed with cocaine (1 per cent.) and adrenalin (1/5000), particularly over the tonsillar regions. Finally the tonsils are swabbed with pure cocain. After an interval of a few moments the opening of each crypt is applicated with 50 per cent. silver nitrate, the applicator resting in the crypt for ten to fifteen seconds. The patient is told to remain quiet for that day, to take a light diet, a cathartic, to spray the throat with a 50 per cent. hydrogen peroxide solution, to suck cracked ice and to apply iced cloths to the neck. As a rule the patient is well in twenty-four hours, but sometimes a second application is necessary. I have never had a patient who has not been cured after the second treatment. The applications are painless and the effect from the silver nitrate is readily explained. This antiseptic is extremely powerful, and on inflamed tissue acts as an astringent. One immediately sees after applying the silver nitrate an appreciable diminution in the size of the tonsil. This in itself is a comfort to the patient. The mouth of each infected crypt is disinfected, and what is of more importance, the shrink-

Fig. 4—The infected tonsil in cross-section. The crypts are distended, being constricted at the neck.

ing process retracts the mucosa at the ostium, so that the deeper portions of the crypt are opened up. Some of the silver nitrate reaches these deeper parts, but what I wish to emphasize mainly is that a sufficient passage remains patent to allow for drainage.

No permanent injury has been known to result from this treatment, when it has been used in competent hands with proper illumination.

THE PREVENTION OF INSANITY: HYGIENE OF THE MIND.

By A. J. ROSANOFF, M.D.,

KINGS PARK, N. Y.

SECOND ASSISTANT PHYSICIAN, KINGS PARK STATE HOSPITAL.

The object of this paper is to present a certain modern standpoint of the etiology of insanity and a review of measures of prevention which have been practised with some degree of success and which may, therefore, be recommended for general adoption.

By way of introduction it may be well to point out two facts, namely, that insanity is very common, at least one per cent. of the population being either insane or congenitally defective, and that it is apparently increasing at a rate which is about two times as great as the rate of increase of the general population.

The Causes of Insanity.—Fifty years ago, when Griesinger spoke of the multiplicity of causes in psychiatry, but little was known of the genesis of the various psychoses. Since then our knowledge has been enriched, so that while to-day we still recognize a multiplicity of causes, we are in a position to distinguish among them *essential* causes and *incidental* or *contributing* causes.

The *essential* causes are but few: chiefly heredity, alcoholism, syphilis, and head injuries. Each of these alone may produce mental alienation or it may render the nervous organization so vulnerable that a breakdown will occur at the occasion of some incidental cause which may be in itself quite insignificant but which here comes to play the rôle of "the last straw that broke the camel's back."

The *incidental* or *contributing* causes are innumerable, for almost any disturbing influence, no matter how slight, may determine an outbreak of insanity in the presence of one of the essential causes. Some, however, are met with in practice with special frequency and therefore seem to possess quasi-specific potency in the production of mental alienation; as being among these may be mentioned unhappy love affairs, pregnancy, abortion, childbirth, lactation, domestic troubles, overwork, business reverses, fright or other emotional shock, grief, and slight indulgence in alcohol.

There are few persons, if indeed there are any, who are so fortunate as to go through life without being repeatedly subjected to the influence of some of these incidental causes: the prevention of insanity consists largely in measures for combating the essential causes—heredity, alcoholism, syphilis, and head injuries.

Heredity.—The fact that nervous and mental diseases are often transmitted by heredity was known to Hippocrates and has since his time been amply illustrated by insane hospital statistics, but the exact conditions under which such transmission occurs have never been fully understood. A recent study has, however, revealed some data which seem to indicate that some forms of insanity are transmitted from parent to offspring in the manner of a trait which is, in the Mendelian sense, recessive to normal.[1] The table which is herewith appended shows the actual findings recorded in the study here referred to; these findings, it will be observed, are in close correspondence with theoretical expectation, which is as follows:

1. Both parents being neuropathic, all children will be neuropathic.

2. One parent being normal, but with the neuropathic taint from one grandparent, and the other parent being neuropathic, half the children will be neuropathic and half will be normal but capable of transmitting the neuropathic make-up to their progeny.

3. One parent being normal and of pure normal ancestry and the other parent being neuropathic, all children will be normal but capable of transmitting the neuropathic make-up to their progeny.

4. Both parents being normal but each with the neuropathic taint from one grandparent, one-fourth of the children will be normal and not capable of transmitting the neuropathic make-up to their progeny, one-half will be normal but capable of transmitting the neuropathic make-up, and the remaining one-fourth will be neuropathic.

TYPES OF MATING	Number of Matings.	Total Offspring.	Neuropathic Offspring.	Normal Offspring.			Died in Childhood	Data Unascertained.
				Neuropathic Progeny.	Without Progeny.	Normal Progeny.		
RR × RR ∞ RR	3	16	10	0	0	0	5	1
DR × RR ∞ DR + RR	19	129	45	14	20	27	20	3
DD × RR ∞ DR	5	18	0	8	2	7	1	0
DR × DR ∞ DD + 2DR + RR	7	54	12	6	18	10	8	0
DD × DR ∞ DD + DR	1	4	0	1	0	3	0	0
DD × DD ∞ DD	0	0	0	0	0	0	0	0

D = Dominant. R = Recessive.
RR = Neuropathic subject (nulliplex inheritance).
DR = Normal subject with neuropathic taint from one parent (simplex inheritance).
DD = Normal subject of pure normal ancestry (duplex inheritance).

5. Both parents being normal, one of pure normal ancestry and the other with the neuropathic taint from one grandparent, all the children will be normal, half of them will be capable, and half not capable of transmitting the neuropathic make-up to their progeny.

6. Both parents being normal and of pure normal ancestry, all the children will be normal and not capable of transmitting the neuropathic make-up to their progeny.

I might add that results similar to those recorded in the table here given have been obtained in a much more extensive study of heredity in feeblemindedness which was recently reported by Goddard.[2]

Alcoholism.—The most trustworthy experimental studies, among which may be mentioned those of Schneider,[3] Mayer,[4] Aschaffenburg,[5] Emith,[6] Kurz and Kraepelin,[7] show that even moderate indul-

gence in alcohol, though producing in the subject a sense of well-being and of increased physical and mental ability, in reality causes impairment of muscular power and coordination and of mental efficiency. In persons of neurotic constitution comparatively slight indulgence has been known to cause severe mental disturbance.

Excessive indulgence produces the sufficiently familiar picture of ordinary drunkenness, and such excesses, if frequently repeated, are apt to give rise to certain psychoses which are specifically alcoholic, that is to say, psychoses which occur only on the basis of chronic alcoholism. These are: delirium tremens, acute hallucinosis, the polyneuritic psychosis, chronic paranoid states, and alcoholic dementia.

Alcoholism is the cause of insanity in from twenty to thirty per cent. of all male admissions to hospitals for the insane; among female admissions the proportion is only about one-fourth as large.

Syphilis.—Syphilis, as is well known, may cause principally three different types of lesions in the brain: (1) active syphilitic lesions (basal meningitis, endarteritis, cerebral gumma), (2) parasyphilitic lesions (general paresis), and (3) postsyphilitic lesions (cerebral arteriosclerosis, softening, hemorrhage).

Cases of insanity which result from syphilitic infection constitute from ten to thirty-five per cent. of all asylum admissions, the proportions varying considerably in different communities and being, as a general rule, low in rural districts and high in urban districts.

Head Injuries.—Head injuries, when sufficiently severe to cause mental disturbance, produce at first an interruption of consciousness which is often followed by an acute disorder known as traumatic delirium and characterized by confusion, disorientation, hallucinations, and violent agitation. This condition has most frequently a fatal termination, but may terminate also in complete recovery or in recovery with more or less pronounced defect which is permanent. The defect consists either in a neurasthenoid state: nervousness, trembling, depression with vague anxious feelings, hypochondriasis, undue fatigability; or it may consist in actual traumatic dementia, affecting principally the power of retention and making it impossible for the patient to remember anything except occurrences of the period prior to the date of his injury. There may also be recurrent seizures, constituting traumatic epilepsy.

General Remarks on Prevention.—The prognosis of insanity of whatever nature or origin is, as a rule, gloomy: some conditions lead invariably to a fatal termination (general paresis, cerebral arteriosclerosis, senile dementia); others are incurable, leading to mental deterioration or simply running a chronic course without deterioration (dementia precox, paranoic conditions, alcoholic dementia, epileptic dementia); still others, though they frequently terminate in recovery, present a pronounced tendency toward recurrency (manic-depressive insanity, hysterical psychoses, acute alcoholic psychoses). Very few cases indeed recover permanently. Further, it must be pointed out that treatment may be palliative but does not materially affect the prognosis, and that in a given case the course and termination will depend simply upon the nature of the disorder and may be predicted without reference to the management of the case. It is plain, therefore, that in coping with the problem of insanity our hope lies rather in prevention than in cure.

Measures for the prevention of insanity may be undertaken by the individual or by society. As far as the average healthy individual is concerned the measures are few and simple; it must, however, be noted as a fact which has been repeatedly demonstrated under the most varied conditions that the great mass of individuals, even if made fully aware of all dangers, will not practise preventive measures in any systematic manner; this is perhaps due to a curious trait of human nature owing to which men are disinclined to believe that any evil may befall them and therefore have a tendency to take chances; further it must be remembered that the great causes of insanity appear in the shape of strong temptations which are difficult, and for some impossible, to resist. However this may be, those who are concerned with the problem of the prevention of insanity would be impractical if they relied entirely upon dissemination of knowledge on this subject among the people with the hope of thus reducing to a material extent the incidence of insanity or even of checking the progress of its increase. Dissemination of knowledge should, I believe, be regarded as a preliminary step which will make possible the application of large measures by society as a whole—and nothing less than that constitutes an effective system of mental hygiene.

The Prevention of Bad Heredity.—Laws prohibiting the marriage of defectives have been enacted in some States (Connecticut, Delaware, Indiana, Kansas, Michigan, Minnesota, New Jersey, North Dakota), but it is difficult to estimate the exact amount of benefit that has been derived from such legislation. In the first place it has not been rigidly enforced, as may be seen from the following quotation: "Of the total number of male patients received [at the Parson's State Hospital for Epileptics, Kansas] during the period who had attained the age of twenty-one years at the time of admission 30 per cent. had been married, and of the females eighteen years of age 56.8 per cent. had been married. Of these married epileptics, 25 per cent. of the men and 40 per cent. of the women had married after the development of epilepsy."[8] In the second place marriage is not necessary for propagation. Moreover, even if it were possible to fully enforce such laws the problem would be but partly solved; for the neuropathic make-up is well known to be transmissible to posterity through one or more generations of persons who are themselves healthy but who nevertheless carry the taint from their ancestors in their germ plasm.

For the neuropathic individual or for the one who, though himself normal, may yet be judged from a study of his family history to carry the neuropathic taint, measures for the prevention of conception have been advocated, particularly by Forel: "Anticonceptional measures also allow unfortunate pathological individuals, whose social and moral duty is to avoid procreation, to satisfy their sexual desire without the fear of bringing into the world miserable abortions, idiots, or invalids."—"If the objection is raised that egoists of both sexes profit by these measures to avoid procreation of children, I repeat once more that this is not to be regretted. Men who possess social sentiments and wish to have children will procreate all the more healthy members of society. What we have most to fear for the future of humanity is the want of social sense, or altruism."[9]

Unfortunately the "social and moral duty" is not

always scrupulously fulfilled by neuropathic individuals. By far more certain is, therefore, sterilization by vasectomy or salpingectomy, or by castration. Castration has been practised in some cases with the consent of the patients and their relatives. The following case is of interest:[10] "Girl of twenty-five years, suffered from epilepsy with occasional severe attacks of delirium; had pronounced nymphomania which had twice led to pregnancy. The children are epileptic and feebleminded and are cared for in a local charitable institution. The patient, physically strong, had been two years in the asylum where she had to be carefully watched on account of her nymphomania; she urged the authorities to discharge her as she was capable of supporting herself. It was suggested to her that she submit to castration, the nature and object of the operation having been fully explained to her. She agreed immediately. Her relatives having also given their consent, she was castrated by a gynecological surgeon. Since her discharge half a year ago she has earned her living outside and 'is satisfied with her condition.'"

In the State of Indiana legislation has been enacted providing for the sterilization of defectives and criminals, and a report has been made of 456 cases of vasectomy performed in compliance with that law at the Indiana Reformatory. This operation can be done easily under local anesthesia. "There is no diminution of the sexual power or pleasure. The discharge at orgasm is but slightly decreased."[11]

Salpingectomy is, of course, a more elaborate operation requiring general anesthesia; but under conditions of surgical asepsis and with a little experience it can be performed practically without danger to the patient.

Aside from the benefit of such prophylactic measures to posterity and to society, it may be pointed out that the subjects may also be benefited in various ways, but especially through freedom from the burden of parenthood, the many phases of which figure so prominently among the contributing causes of mental alienation.

The Prevention of Alcoholism.—From what has already been said concerning the effect not only of excessive indulgence but also of so-called moderate indulgence in alcohol it follows that the advice to the individual can only be: total abstinence without compromise. Those who favor temperance rather than abstinence do so on the basis of the usefulness of alcohol as a food and as a sedative contributing to the recuperative effect of rest by promoting complete relaxation. It is not to be disputed that alcohol does possess these beneficial qualities, but it is not possible to derive the benefit and yet escape the harm from using it. Moreover, moderate indulgence, if regular, leads but too often to the development of uncontrollable craving, increase of dosage, and ultimately to chronic alcoholism. It need hardly be added that alcohol either as a food or as a sedative is not a physiological necessity.

Dissemination of correct knowledge of the effect of alcohol should constitute a part of the program of all public schools. It is necessary before all to dispel the prevailing notions that alcohol is harmful only when taken in excess and that in moderate quantities it is beneficial or even necessary to the laborer or artisan.

Various legislative methods have been tried; of these three systems may be mentioned as having been proved to be in some degree effective: (1) the Gothenburg system, (2) prohibition, and (3) local option.

The Gothenburg system was first introduced in Sweden in 1855 and has since been adopted also by Norway and Finland. The Swedish law of 1855 gives to each municipality the right of prohibiting within its jurisdiction the sale of liquor over the bar or in stores in quantities under forty liters. Retail licenses in limited number—according to population—are awarded by the municipal authorities at public sale to the highest bidder, provided he be a person of good reputation. The law provides further that retail licenses may be awarded to societies, thus making it possible for public spirited citizens to form organizations for the purpose of securing the licenses which are at the disposal of the municipal authorities and thus assuming control of the entire retail liquor trade. Thus was founded for the first time in the city of Gothenburg "The Gothenburg Retail Liquor Stock Company." This and other similar companies derive no profit from the trade, the profits going in part (60-80 per cent.) into the city treasury and in part (20-40 per cent.) into the State treasury. The aim of such companies, in contrast with that of private liquor dealers, is to reduce the consumption of liquors; for that purpose they have established popular-price restaurants for working people, reading rooms, etc.

This system is imperfect in that it fails to control the sale of fermented beverages, affecting only that of distilled liquors. However, a special investigating committee, appointed by the municipal authorities of Gothenburg in 1899, has recommended the extension of the system to embrace the control of beer saloons. In spite of the shortcomings of this system, which are more easily pointed out than remedied, it stands as the most effective and most practical system that has yet been devised, as the following results will show.[12] Prior to 1855 liquor could be purchased in Sweden almost in any cottage. In 1869 there was only one barroom or liquor store to 8,028 inhabitants; in 1880 only one to 13,450 inhabitants. There are 2,400 separate municipalities in Sweden; of these 1,800 have entirely abolished barrooms and retail liquor stores. The consumption of liquor in Sweden was in 1851 22 liters per capita, and in 1896 it had been reduced to 7.2 liters.

Prior to enactment of the laws of 1855 from 25 per cent. to 30 per cent. of all male cases admitted to hospitals for the insane were due to intemperance. Following the enactment of those laws the percentage gradually became less and from 1866 until 1899 it varied between 5.2 per cent. and 7.19 per cent.

It should be added here that recent statistics from other countries show that the percentage of cases of insanity in which alcoholism is the cause approaches that of the older Swedish statistics: State of New York, 31.4 per cent.;[13] State of Massachusetts, 30.6 per cent.;[14] Staffordshire County, England, 26.3 per cent.;[15] Lower Austria, 24.9 per cent.[16]

The introduction of the Gothenburg system in Norway and in Finland has been followed by results similar to those obtained in Sweden.

Prohibition has been tried in several States. In some of these States the prohibition laws have been repealed (Connecticut, Vermont, Massachusetts); in others they have been but recently enacted (Alabama, Georgia, Oklahoma); in still others they have been in force for many years (in Maine since

1851, in Kansas since 1880, in North Dakota since 1889), so that they may be assumed to have been given a thorough practical trial.

It must be observed that owing to the operation of the Interstate Commerce Law a State cannot prohibit the importation of liquors from other States. This circumstance, together with the practical difficulties of enforcing prohibition, reduces materially the possible effectiveness of such laws. Nevertheless it has been amply shown that crime and pauperism have been reduced wherever prohibition laws have been enacted.[17]

Unfortunately the effect upon insanity is not so obvious. We find that in the State of Maine 21.4 per cent. of all male cases admitted to the hospitals for the insane (not counting the cases in which the causes were unascertained) are due to alcoholism,[18] —a figure which is but slightly below those of licensed States. It is clear that this slight difference may possibly be due not to prohibition but to other causes.

Local option seems to be a much more popular measure than State prohibition. It is estimated that only 10 per cent. of the population of the United States is living under State prohibition, while more than 75 per cent. is living under local option, and that over 40 per cent. of those living under local option are in "dry" territory.[19] Thus local option, as compared with prohibition, seems to possess the advantage of being more acceptable to most communities and therefore more practicable.

The effect of no-license under local option is similar to that of prohibition; that is to say, drunkenness, crime, and pauperism are undoubtedly reduced, but the incidence of insanity is but slightly if at all, affected.

The following table shows the reduction of drunkenness which resulted from no-license under local option in several cities in Massachusetts:

ARRESTS FOR DRUNKENNESS.

Cities.	License.		No License	
	Year.	Number of Arrests.	Year.	Number of Arrests.
Brockton	1898	1,627	1899	455
Waltham	1900	631	1901	179
Taunton	1901	1,202	1900	482
Chelsea	1902	1,246	1901	398
Newburyport	1901	673	1902	150
Lowell	1902	4,077	1903	2,304
Salem	1903	1,432	1904	503
Woburn	1903	842	1904	204
Fitchburg	1905	1,160	1906	359
